A PART-TIME JUNIOR CASUALTY OFFICER is required on January 4th, 1930, to assist in the Casualty Department, from 10 a.m. to 3 p.m. (Saturdays 10 a.m. to 1 p.m.), under the direction of the Casualty Officer. The work of this office includes a large number of tonsillectomies and other minor operations.

Candidates must be registered Medical Practitioners, and have held a responsible Hospital appointment.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, December 2nd, 1929, accompanied by copies of not more than three testimonials written specially for the purpose.

The appointment is made for six months, and is non-resident.

Salary at the rate of £150 per annum, with luncheon.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, December 4th, at 3.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary at the Hospital.

By order of the Board of Management,
JAMES McKAY,
Secretary.

November, 1929.

The Hospital for Sick Children,
Great Ormond Street, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on January 1st, 1930.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, December 2nd, 1929, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, December 4th, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By order of the Board of Management,
JAMES McKAY,
Secretary.

November, 1929.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

DOCTORS THEMSELVES
PRAISE
"RYVITA CRISPBREAD"

Dr. . . . . Harley Street, W.1.—"I am already using and prescribing 'RYVITA,' and I think it excellent."

Dr. . . . . S.W.1.—"This product solves the question—the importance of which has recently been brought into such prominent notice.—viz., of finding a wholemeal bread, pleasant to the taste, and demanding thorough mastication."

Dr. . . . . Ledbury.—"Please send 10 lbs. of 'RYVITA.' Everyone prefers the 'RYVITA' to bread. It is far superior from the point of view of health."

Dr. . . . . Bournemouth.—"Am delighted with your 'RYVITA.' Please send me a further 7 lbs."

Dr. . . . . Yeovil.—". . . . I have recommended 'RYVITA' to a large number of my patients, who are highly delighted with it."

Dr. . . . . Cruckerne.—". . . Up to now I think I have consumed personally about 30 lbs. of 'RYVITA.' My boys love it; scores of my patients are eating it."

Dr. . . . . Glasgow.—". . . Many ask about 'RYVITA'; we use nothing else, and always have it on the table for visitors' use as some, like ourselves, are already very fond of it. It is exceptionally good for keeping the gums and teeth in a sound healthy condition. The salivary glands are also stimulated to function in a normal and healthy manner; contributing further to a sound state of oral hygiene. I will be glad to recommend 'RYVITA,' and wish you and your Company every prosperity."

Dr. . . . . Droitwich.—"Kindly send me another 10 lbs. It is the very thing I have been looking for, for years. My household like it very much."

. . . . . *Esq. (Dentist), Wimpole Street, W.*—"I shall be pleased to recommend 'RYVITA' to my patients, especially for children's use."

Dr. . . . . Eastbourne.—"Very delicious to eat."

"*Dr. . . . . S.W.1.* has recommended and distributed several packages to patients of supply he purchased last week, and would be glad of samples for this purpose."

Dr. . . . . Almondsbury.—"I am exceedingly pleased with 'RYVITA,' and personally I have been freer from indigestion while taking it than for many months; consequently, I am recommending it freely in my practice. Send me a supply of samples to give to my patients. I have given several patients some of my own stock to start on."

Dr. . . . Southport.—"Have already induced a number of my patients to use 'RYVITA.' In cases where there has been habitual constipation, the result of eating 'RYVITA' has been excellent and the constipation has yielded without the use of aperients. You cannot make 'RYVITA' too widely known."

(Later letters.)

"I have nothing but good to report regarding 'RYVITA CRISPBREAD.' It has been excellent in all cases of constipation. Send me about 25 booklets, also a sample of 'RYVITA' to patient at address below."

"Some little time ago you brought 'RYVITA' to my notice. I got a large number of my patients to take it regularly. Some of these have been supplied in shops with 'something just as good.' Some are now buying an article which to my mind and experience is not as good as 'RYVITA.' There should not be this risk of their having something else palmed off on the customers."

NOTE.—The originals of all the above letters, are, of course, available, and can be seen by any persons properly interested.

(We could fill many pages with similar letters from Medical Men.)

Advertisements and Communications for our issues dated December 14th, December 21st, and December 28th, 1929: see Notice on Page 2 (adverts.).

In the Insulin Treatment of Diabetes the diet is still a factor of vital importance.

'Allenburys' Diabetic Flour

Is a special preparation of caseins and lactalbumen to which leavening agents are added.

It is a satisfactory and convenient product for the preparation of special foods, free from carbohydrates, and containing a minimum of fat; or definite proportions of these may be added as tolerance increases with the progress of the treatment. The 'Allenburys' Diabetic Flour is compact, convenient to use, and keeps well. From it may be prepared a variety of palatable and highly nutritious foods of special composition. Recipes and directions for use are enclosed with each packet.

COMPOSITION:	Per cent.
SPECIAL CASEIN	87.0
FAT	0.7
SODIUM BICARBONATE	1.6
ACID POTASSIUM TARTRATE	1.6
MOISTURE	9.1

Calorific Value—303 calories per 100 grammes or 1,376 calories per lb.

Further particulars and clinical trial sample will be sent on request.

LEWIS'S STANDARD PUBLICATIONS

With 26 Plates (including 6 coloured) and other Illus., 15 Diagrams, and 34 Charts. Demy 8vo. 30s. net; post. 9d.

A TEXT-BOOK OF INFECTIOUS DISEASES

Being the Third Edition of Goodall & Washbourn's MANUAL OF INFECTIOUS DISEASES.

Revised and in large part rewritten by E. W. GOODALL, O.B.E., M.D., B.S.Lond., lately Medical Superintendent and Lecturer on Infectious Diseases and Fever Hospital Administration at the North-Western Hospital of the Metropolitan Asylums Board; Vice-President (formerly President) of the Section of Epidemiology and State Medicine of the Royal Society of Medicine; etc.

"Dr. Goodall's long and intimate acquaintance with the infectious diseases makes this volume very acceptable."—*The Lancet.*

RECENTLY PUBLISHED. EIGHTH Edition. With 2 Plates and 91 other Illus. Demy 8vo. 21s. net; post. 9d.

HYGIENE AND PUBLIC HEALTH

(PARKES AND KENWOOD).

Revised by HENRY R. KENWOOD, C.M.G., M.B., F.R.S.Edin., D.P.H.Lond., Emeritus Professor of Hygiene and Public Health in the University of London, etc.; and HAROLD KERR, O.B.E., M.A.Dunelm, M.D.Edin., D.P.H.Camb., Professor of Hygiene and Public Health in the University of Durham, etc.

"Here we have a quarry of concise information valuable to students and practical workers, a bargain at the price asked for it."
—*British Medical Journal*

With 186 Illustrations, included in 93 Plates (1 Coloured) and the Text. Demy 8vo. 25s. net; postage 9d.

CHRONIC (Non-Tuberculous) ARTHRITIS

Pathology and Principles of Modern Treatment.

By A. G. TIMBRELL FISHER, M.C., F.R.C.S.Eng., late Hunterian Professor, Royal College of Surgeons of England; Assistant, Surgical Unit, University College Hospital, etc.

"Mr. Timbrell Fisher has established the existence of facts hitherto unknown and has made valuable contributions to our knowledge. His book is to be recommended."—*British Medical Journal.*

BY THE SAME AUTHOR.

With 79 Illustrations on 40 Plates and 1 Text-figure. Demy 8vo. 12s. 6d. net; postage 6d.

INTERNAL DERANGEMENTS of the KNEE-JOINT:

Their Pathology and Treatment by Modern Methods.

"An admirable monograph which may be regarded as a type of what a monograph should be."—*The Practitioner.*

BY THE SAME AUTHOR.

With 62 Illustrations. Demy 8vo. 9s. net; postage 5d.

TREATMENT BY MANIPULATION

A Practical Handbook for the Practitioner and Student.

"This edition will no doubt be even more welcome to the profession than its predecessor."—*The Lancet.*

"We can strongly recommend this book . . . the illustrations are excellent."—*St. Bart.'s Hospital Journal.*

Recently Published. FIFTH Edition, Revised and greatly enlarged. Medium 8vo. With 249 Illustrations. 31s. 6d. net; postage 9d.

THE DIAGNOSTICS AND TREATMENT OF TROPICAL DISEASES

A Compendium of Tropical and other Exotic Diseases.

By E. R. STITT, A.B., Ph.G., M.D., Rear-Admiral, Medical Corps, and Surgeon-General, U.S. Navy; Graduate London School of Tropical Medicine, etc.

"A very wide field is covered . . . very valuable addition to the text-books of Tropical Medicine."—TROPICAL DISEASES BULLETIN.

BY THE SAME AUTHOR.

EIGHTH Edition. With 1 Plate and 683 Figures. Post 8vo. 24s. net; postage 9d.

PRACTICAL BACTERIOLOGY, BLOODWORK, AND ANIMAL PARASITOLOGY

Including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes.

"This is essentially the practical pathologist's handbook."
THE LANCET.

With 25 Illustrations, including 17 Plates. 9s. net; postage 5d.

STERILITY IN WOMEN: Diagnosis and Treatment

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. & Edin., Surgeon to the Hospital for Women, Soho Square, London, etc.
Author of "The Effects of Radium upon Living Tissues," etc.

"The monograph shows in every page evidence of rich personal experience, and will well repay the most careful study."—THE LANCET.

SIXTH Edition. Plates from Original Drawings (6 in Colours) and other Illus. in Text. Demy 8vo. 30s. net; post. 9d.

ON DISEASES OF THE LUNGS AND PLEURÆ

Including TUBERCULOSIS AND MEDIASTINAL GROWTHS.

By Sir RICHARD DOUGLAS POWELL, Bt., K.C.V.O., M.D.Lond., F.R.C.P.; and Sir PERCIVAL H. S. HARTLEY, C.V.O., M.D.Camb., F.R.C.P., Physician, St. Bartholomew's Hospital, etc.

". . . can be confidently recommended as a safe guide to the practitioner in search of authoritative medical opinion in this country at the present time."—BRITISH MEDICAL JOURNAL.

FIFTH Edition. Revised and Enlarged. With 11 Plates (6 Coloured) and 76 other Illustrations. Demy 8vo. 21s. net; postage 9d.

MIND AND ITS DISORDERS:

A Text-Book for Students and Practitioners.

By W. H. B. STODDART, M.D.Lond., F.R.C.P., Physician for Mental Diseases to St. Thomas's Hospital, etc.

". . . students, practitioners, and specialists will all find much of value in this eminently readable volume."—THE PRACTITIONER.

THIRTEENTH Edition. Thoroughly Revised. With 9 Col. Plates and 278 other Illus. Demy 8vo. 21s. net; post. 9d.

SWANZY'S HANDBOOK OF

DISEASES OF THE EYE AND THEIR TREATMENT

Revised and Edited by LOUIS WERNER, M.B., F.R.C.S.I., Sen. Mod., Univ. Dub.; Surgeon, Royal Victoria Eye and Ear Hospital; Professor of Ophthalmology, University College, Dublin; and Examiner in Ophthalmology, Dub. Univ.

"Swanzy's text-book undoubtedly remains one of the best. One of the features of this volume is the excellence of the illustrations."
—THE LANCET.

THIRTEENTH Edition. Royal 32mo. 4s. 6d. net; postage 3d.

WHAT TO DO IN CASES OF POISONING

By W. MURRELL, M.D. Revised by P. HAMILL, M.D., D.Sc., F.R.C.P., Lecturer on Pharmacology and Therapeutics, St. Bartholomew's Hospital Medical School.

"Its value to the practitioner and medical student is, if possible, greater than ever."—BRITISH MEDICAL JOURNAL.

SECOND Edition. Thoroughly Revised. With 159 Illustrations (6 in Colours) from original Drawings and Photographs. Demy 8vo. 12s. 6d. net; postage 9d.

THE PATHOLOGY OF TUMOURS

By E. H. KETTLE, M.D., B.S.Lond., Professor of Pathology, University of London, St. Bartholomew's Hospital Medical College, etc.

". . . A model of conciseness. . . . The present edition is a worthy successor to the first."—THE LANCET.

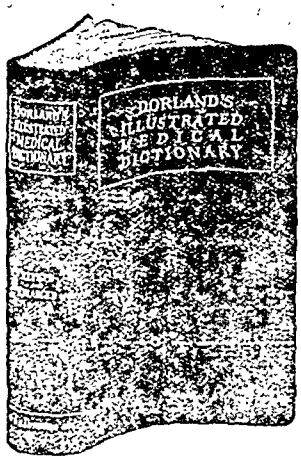
WHY EVERY MEDICAL MAN SHOULD HAVE

DORLAND'S ILLUSTRATED MEDICAL DICTIONARY

FIFTEENTH EDITION



"The dictionary has received the most thorough revision of its long career, and several thousand terms noted in the most recent medical literature have been added. . . . It may be said that the new edition fully justifies the great amount of work that has evidently been devoted to its preparation."—BRITISH MEDICAL JOURNAL.

"In these days of endocrinology, immunology, biochemistry, psychotherapy, and what not other bypaths of medical science, a complete and up-to-date dictionary is an indispensable desk-book. All our wants are fully met by Dorland's Medical Dictionary."—EDINBURGH MEDICAL JOURNAL.

"It is infinitely more than a medical dictionary, and takes on the character of a condensed encyclopædia. . . . Such a work as this should undoubtedly be in the hands of every medical practitioner, who will find it invaluable."—JOURNAL OF THE MEDICAL ASSOCIATION OF SOUTH AFRICA.

"The most convincing testimony to its value will be gathered when we state that the volume has never been allowed to be taken from our desk, and that we find it of the greatest value, having occasion constantly to refer to it. . . . An absolute necessity for medical men."—JOURNAL OF TROPICAL MEDICINE.

A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, Etc. By W. A. NEWMAN DORLAND, A.M., M.D., Member of the Committee on Nomenclature and Classification of Diseases of the American Medical Association. Octavo of 1,427 pages, with 525 illustrations, 105 in colours. Flexible binding, 35s. net; with Thumb Index, 37s. 6d. net.

Cecil's Text-book of Medicine

"The plan of presenting a textbook in which a large number of authorities have collaborated has obvious advantages to the student preparing for his final examination, and to the practitioner of more mature years seeking recent and reliable information. Dr. Cecil is to be congratulated on the success with which he has brought this magnum opus into being."—BRITISH MEDICAL JOURNAL.

By 130 Authors. Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical School. Octavo of 1,500 pages, illustrated. Cloth, 40s. net.

Garrison's History of Medicine

"The most readable, and in some respects the most valuable of medical histories. The record of progress is enlivened throughout by touches of human interest. The author is never dull. . . . We congratulate him on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."—BRITISH MEDICAL JOURNAL.

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other pictures. Fourth Edition. Cloth 55s. net.

Jackson & Coates' Nose, Throat, and Ear

"It would be impossible to appraise the merits of all the articles, so varied and so diverse, but as they must be taken collectively, it may be said that on the whole they maintain a high level and give a faithful picture of the best modern practice, with copious illustrations and admirable coloured plates."—BRITISH MEDICAL JOURNAL.

Edited by CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., and GEORGE M. COATES, M.D., A.B., F.A.C.S. Assisted by CHEVALIER L. JACKSON, A.B., M.D. Octavo of 1,177 pages, with 657 illustrations, and 27 inserts in colours. Cloth, 60s. net.

Blumer's Bedside Diagnosis

". . . the book is well bound, the print is excellent, and the illustrations carefully chosen and well reproduced. Not only is each volume indexed, but a separately bound index to the whole three volumes is provided, so that fruitless searching in the wrong volume can be avoided. The physician will find it hard to get a finer book."—THE LANCET.

Edited by GEORGE BLUMER, M.D., David P. Smith Clinical Professor of Medicine, Yale University Medical School. Three octavo volumes, totalling 2 820 pages, with 890 illustrations.

Per set, Cloth, £6. 15s. net. Index volume free.

Saunders' New Illustrated Catalogue sent Post-free on Request.

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street LONDON, W.C.2.

SLEEP AND THE TREATMENT OF ITS DISORDERS

By R. D. GILLESPIE, M.D., D.P.M., Physician and Lecturer in Psychological Med., Guy's Hosp., London.

CONTENTS: Physiology and Pathophysiology; The Effects of Sleeplessness; Pathology of Sleep; Treatment; Theories of the Nature of Sleep.

"Since no comprehensive monograph on the subject of sleep and its disorders has appeared in English for some years the book supplies a definite demand, and it gives an entirely up-to-date presentation of the subject. The book may be read with pleasure and profit by students and practitioners."—LANCET.

Size 7½ × 5. Pp. viii + 267. With 5 Figures. Price 7s. 6d. Postage 6d.

THE EYE IN GENERAL MEDICINE

The Constitutional Factor in the Causation of Diseases, with special reference to the Treatment of Diseases of the Eye.

By A. MAITLAND RAMSAY, M.D., LL.D., Fellow of Royal Faculty of Physicians and Surgeons, Glasgow; Consulting Ophthalmic Surgeon, Glasgow Royal Infirmary.

Second Edition. 8½ × 5½. Pp. ix + 255. Price 12s. 6d. Postage 6d.

TREDGOLD'S MENTAL DEFICIENCY

"Indispensable as a trustworthy guide to the most recent scientific and sociological findings in this department of human activity . . . should be read and referred to by all who are called into relation with the mentally defective."—JOURNAL OF MENTAL SCIENCE.

Fifth Edition. Size 9 × 6. Pp. xvi + 520, with 35 Plates. Price 25s. Postage: Inland 9d.; Abroad 1s.

MEDICAL LABORATORY METHODS AND TESTS

By HERBERT FRENCH, M.A., M.D.Oxon., F.R.C.P.Lond., Physician, Guy's Hospital, etc.; and TALLENT NUTHALL, M.D.Lond., Medical Assistant, Guy's Hospital.

"As might be expected, a considerable number of new tests have been introduced. . . . In all cases only the simpler methods are described, and it is therefore easy to find those tests which really fall within the scope of the average technicus."—JOURNAL OF CLINICAL RESEARCH.

Fourth Edition. Crown 8vo. Pp. xii + 214, with 3 Col. Plates and 62 Figs. Price 7s. 6d. Post. 6d.

7 & 8, Henrietta Street, Covent Garden, London, W.C.2.

HENRY KIMPTON, 263, HIGH HOLBORN, LONDON, W.C.1.

CASSELL AND COMPANY, LTD.

NINTH EDITION. NOW READY.

CLINICAL METHODS

By ROBERT HUTCHISON, M.D.Edin., F.R.C.P.Lond., and DONALD HUNTER, M.D., F.R.C.P.Lond.

For the Ninth Edition this Manual, now in its 87th thousand, has been thoroughly revised by Dr. Hutchison, with the collaboration of Dr. Donald Hunter, whose name replaces that of the late Dr. Rainy on the title-page. Help has also been given in special sections by recognized authorities on the subjects.

The illustrations have been reinforced by four new Plates, two of them in colour, and by some new Figures in the Text.

Foolscap 8vo, 698 pages. With 18 Colour and 2 Half-tone Plates, and 152 Figures in the Text. 12s. 6d. net.

HERMAN'S DIFFICULT LABOUR

A Guide for Students and Practitioners.

Revised by CARLTON OLDFIELD, M.D., F.R.C.P.Lond., F.R.C.S.Eng.

"The book is in a class by itself. . . . Can be most cordially recommended to such practitioners of the present generation as are not already familiar with it, as well as to students, and especially house-surgeons."
—BRITISH MEDICAL JOURNAL.

Seventh Edition. Crown 8vo. 574 pages. With 8 Radiographic Plates and 197 Illus. in the text. 16s. net.

THE ESSENTIALS OF MEDICAL DIAGNOSIS

A Manual for Students and Practitioners.

By Sir THOMAS HORDER, Bart., K.C.V.O., M.D., F.R.C.P.Lond., and A. E. COW, M.D., F.R.C.P.Lond.

"Well written and thoroughly practical."—BRITISH MEDICAL JOURNAL.

"The popularity of this manual seems assured. It is practical, yet sufficiently detailed to become one of the student's recognized textbooks."—PRACTITIONER.

Crown 8vo. 702 pp. With 8 Colour and 11 Black-and-White Plates, and Figs. and Charts in the text. 16s. net.

X-RAY DIAGNOSIS

A Manual for Surgeons, Practitioners, and Students.

By J. MAGNUS REDDING, F.R.C.S.Eng., Senior Surgical Radiologist to Guy's Hospital.

"An outline of radio-diagnosis—straightforward, well balanced, and well illustrated. . . . Can be warmly commended to all students of the subject."—LANCET.

Medium 8vo. 244 pages. With 80 Radiographic Plates. 21s. net.

MODERN OPERATIVE SURGERY

Edited by H. W. CARSON, F.R.C.S.Eng.

"A very welcome change from the usual type of operative surgery textbook. . . . The volumes . . . form most worthy companions to the already well-known three-volume 'System of Surgery.'"
—BRITISH JOURNAL OF SURGERY.

Two Volumes. Medium 8vo. 1,594 pp. With 735 Illustrations in the Text and 6 Plates. £3 3s. net the set.

CASSELL & CO., LTD., LA BELLE SAUVAGE, LONDON, E.C.4.

THE PRACTITIONER

THE LEADING MONTHLY MEDICAL JOURNAL

FOUNDED IN THE YEAR 1868

CONTROLLING EDITOR:
SIR HUMPHRY D. ROLLESTON, BART., G.C.V.O., K.C.B., M.D., F.R.C.P.
ASSOCIATE EDITOR:
R. SCOTT STEVENSON, M.D., F.R.C.S.E.

NO practitioner, whether in general, specialist, or consulting practice, or in the public services, can afford nowadays to be out of touch with the most recent advances in medicine. The best way to keep up to date is by the regular and unhurried perusal of a *monthly* medical journal. THE PRACTITIONER is one of the most attractively produced monthly journals in the world, it publishes only articles which have been especially written for it, and it is carefully edited. The new volume begins on January 1st with a greatly enlarged Special Number, profusely illustrated, which contains particulars of a Fifty Guinea Prize for junior practitioners. A specimen copy of THE PRACTITIONER will be sent free to any medical practitioner on application to the General Manager.

Annual Subscription £2 . 2 . 0 post free to any part of the world.

THE PRACTITIONER, 6-8, BOUVERIE ST., LONDON, E.C.4.

1929 Appleton Books

MINOR SURGERY

By EDWARD M. FOOTE, M.D., and EDWARD M. LIVINGSTON, B.Sc., M.D.

"Should prove invaluable to the Practitioner. The teaching is quite modern and at the same time sound and practical. The majority of the illustrations are beautifully reproduced photographs."—LANCET.

420 Illustrations. 35/-.

PROCTOLOGY

By FRANK C. YEOMANS, M.D.

"A magnificent production which will take its place as one of the leading books in the English language on disease of the rectum and the pelvic colon."—LANCET.

421 Illustrations and Coloured Plates. 45/-.

GONORRHŒA, Male and Female

By GEORGE R. LIVERMORE, M.D., and EDWARD A. SCHUMANN, M.D.

Particular attention is paid to pathology and diagnosis, with the idea of meeting every possibility. Every known therapeutic course has been delineated.

63 Illustrations. 21/-.

A SURGICAL DIAGNOSIS

By J. L. DONHAUSER, M.D.

"Dr. Donhauser may well be pleased with the results of what must have been prodigious labour. He has produced a book of sound surgical teaching and attacks the problems of diagnosis in a way that is both original and satisfactory."—LANCET.

35 Illustrations and many charts. 42/-.

PRINCIPLES OF PATHOLOGY

By H. D'ARCY POWER, M.D., and WILLIAM W. HALA, M.D.

This new book on general and regional pathology lays stress throughout on the functional derangements that are the cause of, and are caused by, disease processes. 293 Illustrations. 42/-.

BODILY CHANGES IN PAIN, HUNGER, FEAR, AND RAGE

By WALTER B. CANNON, M.D.

An account of recent researches into the function of Emotional Excitement. The New Second Edition incorporates ingenious new methods of study and interesting new results. Illustrated. 12/6.

Supplement to the

BILLINGS-FORCHHEIMER'S THERAPEUSIS OF INTERNAL DISEASES

Care and Management of Maladies and Ailments other than Surgical.

With the issue of this Supplement of 760 pages this important work has been brought fully up to date. Six volumes, Desk Index, and Supplementary Volume. Over 6,000 pages, fully illustrated.

Maroon buckram £12 12s.

Supplementary Volume sold separately £1 10s.

Electrocardiograph without case

CAMBRIDGE PORTABLE CARDIOGRAPH

Electrocardiograph in case

A novel form of film camera enables four films (6¼ × 3¼ inches) to be exposed in three sections in the normal way, without using a dark room. Non-immersion electrodes are used. The source of light is a 12-volt lamp. The outfit, including the battery, is contained in compact carrying cases.

This apparatus is similar in principle to the standard Einthoven electrocardiograph (and produces exactly similar records), but is arranged in a portable form, so that it may be easily taken to a patient's house.

World Wide acceptance of the Victor Shock-proof X-Ray unit

The First Installation of a Victor Shock-Proof X-Ray Unit. Photo courtesy of Neurological Institute, New York, N.Y.

Shock proof. Silent operation.
Compact. Self-contained. Greater flexibility.
Increased diagnostic range.
Eliminates overhead system.
Longer tube life. Same tube used over and under table.
Not affected by altitude or humidity.
Introduces a new principle of control.
Consistent results.
Complete diagnostic service.
Unit construction permits variation according to specialty.
No danger around ether, when setting fractures, etc.

THE sustained interest in, and orders received up to September 1st for this 100% electrically safe X-ray unit, are eloquent of approval generally of this epochal development.

In the United States alone fourteen states are represented in the list of users of the Victor Shock-Proof X-Ray Unit, some of these states accounting for several.

The list of foreign countries includes England, Norway, Australia, Mexico, Brazil, Argentina, Dutch East Indies, Guatemala and Colombia, one of these countries accounting for six outfits.

There are logical reasons why roentgenologists and institutions are selecting the Shock-Proof Unit as an important part of their modern diagnostic facilities. If you are not familiar with this apparatus, write for a detailed description.

We shall be pleased to demonstrate the Shock-Proof Apparatus to you at any time.

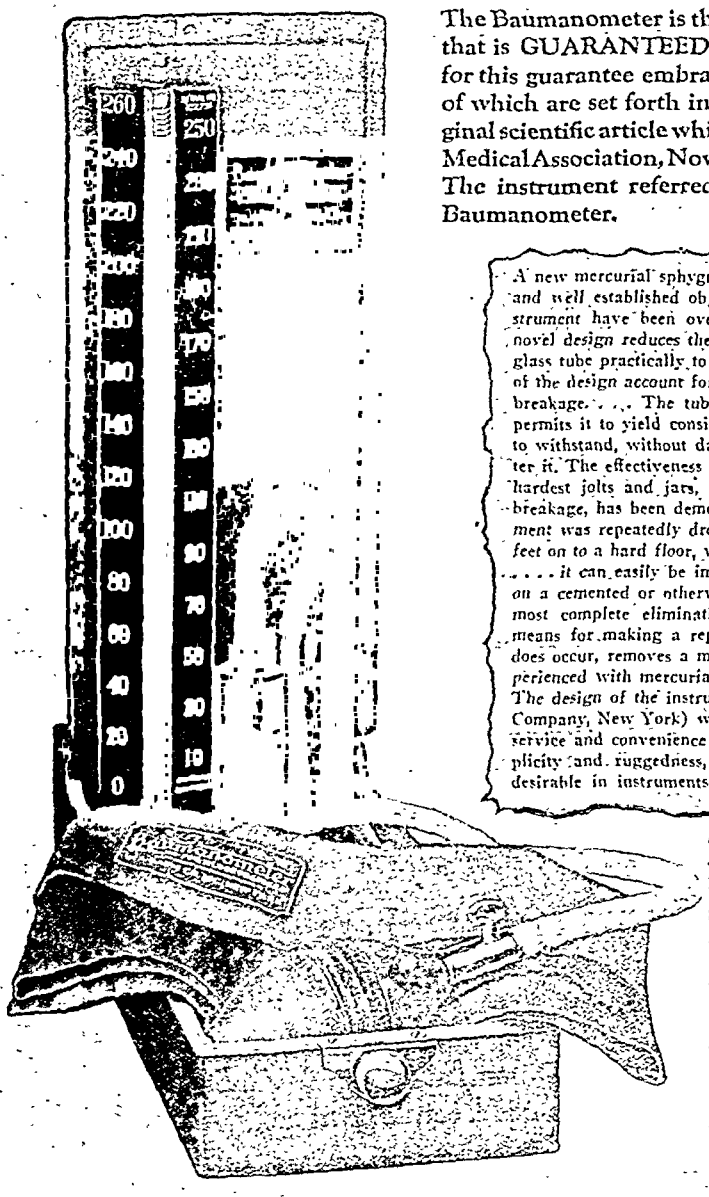
The *Lifetime* GUARANTEE
—*its TRUE significance*



The Baumanometer is the only instrument in all of the world that is GUARANTEED against glass breakage. The *reason* for this guarantee embraces certain facts, the more important of which are set forth in the following excerpts from an original scientific article which appeared in the Journal American Medical Association, Nov. 20, 1926, Vol. 87, *pp.* 1742 and 1743. The instrument referred to, of course, is the new Lifetime Baumanometer.

> A new mercurial sphygmomanometer in which several important and well established objections to this type of bloodpressure instrument have been overcome has been developed recently. Its novel design reduces the possibility of accidental breakage of the glass tube practically to the vanishing point . . . Several features of the design account for the almost complete elimination of glass breakage. . . . The tube is held in a resilient mounting which permits it to yield considerably to side and end thrusts and thus to withstand, without damage, shocks that would otherwise shatter it. The effectiveness of this unique mounting in absorbing the hardest jolts and jars, and thus protecting the glass tube from breakage, has been demonstrated. A completely assembled instrument was repeatedly dropped in all positions from a height of 4 feet on to a hard floor, without injury to the tube in any instance. . . . . it can easily be imagined what would have been the effect on a cemented or otherwise rigidly mounted tube. . . . . The almost complete elimination of glass breakage, and the simple means for making a repair in the rare case in which breakage does occur, removes a most exasperating difficulty heretofore experienced with mercurial sphygmomanometers. . . .
> The design of the instrument shown (made by the W. A. Baum Company, New York) was developed along the lines of maximum service and convenience to the user, without the sacrifice of simplicity and ruggedness, which experience has shown to be so desirable in instruments of this character.

That is why the Baumanometer is guaranteed against glass breakage; and why no other instrument is so guaranteed at all—much less for the user's *lifetime!*

That is why we can assure you of perfect, uninterrupted bloodpressure service for your lifetime... *You couldn't expect more, —don't be satisfied with less.*

Lifetime Baumanometer

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York, U. S. A.

Internal and External Germicide. **T.C.P.** (Trichlorophenylmethyliodosalicyl)

T.C.P. is a synthetic chemical of the "Organopolyhalogens" class. It is not caustic and it is a perfect disinfectant of the alimentary tract.

T.C.P. is probably the only organic germicide able to produce in the system oxygen in the nascent state. In consequence, T.C.P. entirely neutralises the action of bacterial toxins.

Germicides made only from coal tar derivatives or from heavy metals (arsenic, mercury, etc.) may have some germicidal effect, but lack entirely oxydising properties.

T.C.P. and all Organopolyhalogens exert a powerful stabilising effect on the nerves, and induce a healthy condition of the pluriglandular system. In these cases T.C.P. Colloidal Emulsion is most suitable, as well as for rheumatism, neuralgia, and many other ailments.

EXTERNALLY T.C.P. prevents infection, suppresses inflammation, promotes rapid healing and smooth granulation. Every form of sepsis yields readily to T.C.P.

INTERNALLY T.C.P. is better administered under the form of Colloidal Emulsion.

For all forms of DYSENTERY, ENTERITIS, GASTRO-ENTERITIS, HYPERTENSION, ARTERIO-SCLEROSIS, etc.

.....*M.B. (London), some time Deputy Commissioner of Medical Services, London Region, Ministry of Pensions; lately Medical Superintendent, Ministry of Pensions Hospital, ... , reports:—*

"My experience of it has extended over more than six years. In many important operations, especially those for THORACOPLASTY, we entirely gave up the use of the Carrell-Dakin Solution in favour of T.C.P.

"In my practice it has been found that the use of T.C.P. Liquid in treatment of chronic sinus cases, following old fracture of bones, in war wounds, or in cases of TROPHIC ULCERATION and ABSCESSES, ... the effects have been surprising.

"The most spectacular use of this preparation has only been known to me during the last 12 months, when it has been used internally, in combination with Colloidal Silicate of Aluminium, as an intestinal and gastric antiseptic; the curative effect of this combination in cases of HYPERCHLORHYDRIA, ... has been amazingly satisfactory.

"... A vast number of people of middle age suffer from digestive disturbances; have poor appetites; have gastric and intestinal spasms; and SLEEP VERY BADLY . . .

"... If the medical profession generally could be induced to try the effects of T.C.P. they would be amazed at the success of this preparation, which is an ideal gastro-intestinal antiseptic.

"A suitable mixture is prepared by British Alkaloids Limited known as 'T.C.P. B^3 COLLOIDAL EMULSION,' which is a combination of the original antiseptic Trichlorophenylmethyliodosalicyl with another organopolyhalogen containing the Bromine element, together with Colloidal Aluminium silicate, glycerine, and a suitable adjuvant. This mixture should be taken twice or thrice daily in doses of one tablespoonful of the emulsion in 4 or 5 tablespoonfuls of cold water before breakfast, and before the evening meal; in severe cases an extra and similar dose before luncheon is useful.

"In my experience of over 12 months this treatment has been most efficacious—in many cases which have almost defied treatment by the ordinary alkaline medication."

T.C.P. SOLUTION 3/- 8-oz. bottle. T.C.P. B^3 COLLOIDAL EMULSION 4/- 8-oz. bottle.

Literature will be gladly sent to any member of the Medical Profession.

Mistol

The normal secretion of the mucous membrane of the nose and throat may easily be changed in character, due to irritation or infection, so that it becomes itself, irritating, excessive in quantity and deficient in quality.

Mistol, being an oily preparation, clings tenaciously to mucous membranes and is not easily washed away by the natural secretions. Thus it keeps its soothing and astringent ingredients in direct contact with the mucous membrane for a considerable length of time. Proper application, too, is made easy and certain.

The Mistol formula is in strict accord with the opinions of leading nose and throat specialists, verified and approved by the most exhaustive research and clinical tests. It contains ingredients of the highest quality selected and compounded to exacting pharmaceutical standards.

Nujol Laboratories, 128, Albert Street, Camden Town, N.W.1

Sanatogen Strengthens but does not Irritate

The value of Sanatogen as a tonic food lies in its ready absorption. Even the weakest stomach can easily digest Sanatogen. For this reason Prof. Ewald of Berlin University, amongst others, has frequently given it in typhoid fever and reports that it is promptly absorbed during the febrile period with apparently the same ease as under normal conditions.

Writing in *"The Medical Press and Circular,"* a leading authority says:

"Sanatogen is readily absorbed by the stomach and has an immediate and remarkable effect, shown by a steady increase of body-weight and of muscular strength and energy."

SANATOGEN

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

DINNEFORD and Co. LTD.

"I give BEMAX to all children showing signs of B. coli infections of the Urinary Tract." Dg.29

Co. 13. "The most striking result was in the case of a child, aged 6, with chronic constipation, for which she had been drugged for weeks—Cascara, Paraffin, etc. Dessertspoonful of Bemax twice a day produced a healthy, active child."—M.D.

BEMAX is the most concentrated extract of natural Vitamin B. Many important Clinics and Child Welfare Centres rely on it to supply the "B" Vitamin content of the diet of their patients. That satisfactory results are achieved is evident from reports which reach us from doctors in charge of these organisations. Bemax has proved of inestimable value in severe cases of Constipation, Intestinal Toxæmia, Debility, Neurasthenia, Rheumatism, Gastric Disturbances, and Skin Diseases of all kinds—in fact, in all cases which show signs of B Vitamin deficiency.

Laboratory reports on Bemax and a full sized tin for trial will be sent to any medical man interested on receipt of his professional card.

"I would say that the addition of more Vitamin B (in the form of Bemax) has proved most valuable, and that, in certain children this addition has been of vital importance and the main cause of rapid improvements."
—B.A.Camb.(Hons.), M.B., B.C.

N.S.D. 18. "Have exhibited 'Bemax' in a number of cases of disabled men; it has certainly proved beneficial, especially in gastric atony."—M.D.

KOLYNOS
DENTAL CREAM

(Made in England)

The properties desirable in a dentifrice have been specified as follows, viz.:

Antiseptic.	Harmless to Mucous Membrane.
Pleasant Flavour.	Non-poisonous to the user.
Mildly Alkaline.	Must not alter reaction of the Saliva.
Contains Chalk as an Abrasive.	Must not destroy Salivary ferments.
Contains Soap as an Emulsifier.	Must not inhibit the secretion of the Saliva.

Twenty years of varied and painstaking laboratory experimen s with the wide and ever-increasing endorsement of the profession have demonstrated that these qualities are embodied in Kolynos Dental Cream.

Write TO-DAY for free professional samples, literature, etc.

KOLYNOS INCORPORATED
(Laboratories and Offices)
CHENIES STREET, LONDON, W.C.1

KOLYNOS DENTURE POWDER

An entirely new preparation for effectively cleaning artificial teeth. Can be used on the most delicate dental plate with complete safety and satisfaction.

Antiseptic. *Convenient in use.*

WHY K-Y JELLY FOR CATHETER CASES?

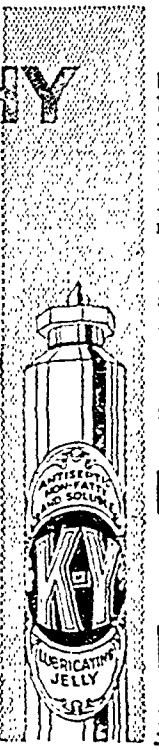
K-Y Jelly reduces the discomfort of instrument-introduction and manual examination more efficiently than any similar lubricant. It is far more "slippery" than petrolatum, flows easily, and never binds. It is emollient and antiseptic and does not interfere with the application of local remedies.

K-Y Jelly is prepared from certain vegetable substances blended in correctly balanced proportions with boric acid, and never spoils or becomes rancid or odorous.

Physicians and Surgeons are invited to write for samples to *Dept. B*, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating the name of their local supply house.

* * *

K-Y Lubricating Jelly is obtainable from medical supply houses and pharmacists throughout the world. Tubes in cartons, 1/3 (Hospital size, 2/6).



K-Y JELLY IS A MORE EFFICIENT LUBRICANT

JOHNSON & JOHNSON (GT. BRITAIN) LIMITED, SLOUGH AND LONDON

Bowel Infection
in
DISEASES OF THE NERVOUS SYSTEM

A generation ago the origin of diseases of the nervous system presented for the most part a tangle of insoluble medical problems. The scientific worker of to-day, however, has so far cleared a way through the jungle as to make its ultimate conquest a certainty. In disorders of the nervous, as of other bodily systems, the overwhelming part played by toxæmic agencies has become generally recognised.

"The first routine duty of the physician called upon to face nervous symptoms in which there is no routine cause, such as arsenic, lead, or alcohol, is to search for a focus of infection. In some cases this will be found in the nasal cavity and its accessory sinuses, or in the mouth or pharynx, but in the great majority the seat of mischief lurks in the bowel. Should constipation and anæmia be associated with otherwise obscure nervous symptoms, there need be little hesitation concerning the diagnosis, and still less about the treatment. Bowel toxæmia proclaims itself in the boldest of type, and the experienced physician often recognises auto-intoxication at a glance. Happily, in all such cases, now that the problem of intestinal disinfection has been solved by the introduction of the benzene derivative Dimol, it is possible to clear out the immediate cause of the trouble *in situ*."
———, M.D.(Ed.), Cavendish Square, W.1.

A new era in the treatment of many diseases of the nervous system is thus opened up by the discovery of this benzene derivative. With the introduction of Dimol, the **bactericidal equivalent** of 140 grains pure phenol can be administered four or five times a day without affecting the mucosa or producing any toxic effect whatever.

Samples and Literature will be sent on application to the

Dimol Laboratories, Limited, 40, Ludgate Hill, London, E.C.4

The Doctor orders *Thermogene*

BECAUSE:

(1) He knows it to be cleanly in use; whereas poultices and liniments soil clothes and skin, thus making examination with hand or stethoscope both unpleasant and difficult.

(2) He knows it to be fool-proof. It is always ready and calls for no skill in preparation or application. It is never too hot, and cannot get cold and clammy. Scalding and chilling are alike impossible.

(3) He knows that in addition to—or because of—its definite therapeutic action in promoting surface circulation and in stimulating healthy metabolism it invariably comforts and soothes the patient, and eases his pain.

Thermogene is carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice. The Thermogene Co., Ltd., Queen's Road, Hayward's Heath, Sussex.

THERMOGENE

MEDICATED WADDING

BOOTS PRODUCTS

Hexyl-Resorcinol (BOOTS)

is administered in enteric-coated tablets or in capsules. They contain the same dose, and the indications for their use are the same.

Boots Specification—White solid, crystallising in fine glistening needles, contains 100 per cent. of Hexyl-Resorcinol.

Melting point 67°—68° C. Phenol-coefficient (Rideal-Walker) not less than 50.

HEXYL-RESORCINOL is a recently discovered alkyl derivative of the well-known antiseptic Resorcinol.

Tested by the usual Rideal-Walker method of standardising disinfectants, HEXYL-RESORCINOL (BOOTS) is shown to possess extraordinary bactericidal potency numerically very many times greater than that of the ordinary organic disinfectants in general use. At the same time, the prescribed dose has no toxic action towards man or animals.

HEXYL-RESORCINOL (BOOTS) is supplied in Enteric-coated Tablets—in bottles of 25 and 100 tablets.

Special Gelatin Capsules—in boxes of 24 and 100 capsules—are also available.

WHEN MUCH DEPENDS ON PROPER NUTRITION

At periods when an adequate supply of easily digested nourishment is of paramount importance, the addition of Marmite to the normal diet has frequently proved extremely effective. The rich supplies of Vitamin B in Marmite, which is a highly concentrated extract of Yeast, are particularly beneficial for growing children, for convalescents and for expectant or nursing mothers.

MARMITE

Medical Practitioners are invited to write for a sample of Marmite, together with full evidence of its usefulness. The Marmite Food Extract Co., Ltd., 59, Eastcheap, London, E.C.3.

Valentine's Meat-Juice

In the **Treatment** of **Weak Babies**, in the **Gastric** and **Enteric Troubles** of **Infants** and in the **Wasting** and **Febrile Diseases** of **Children**, the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** has been **Demonstrated** in

Hospitals for Children.

The quickness and power with which **Valentine's Meat-Juice** acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

VITAD PALATINOIDS

¶ VITAD *is the unsaponifiable fraction of Cod-Liver Oil* containing in a high concentration Vitamins A and D.

¶ While presenting practically the full medicinal properties of Cod-Liver Oil, it is free from the nauseating oily fraction. Being exhibited as a Palatinoid, it is protected by the hermetically sealed non-actinic covering from all chance of oxidation and light action, thus ensuring a standard dose at all times.

¶ Palatinoid Vitad is put up in bottles of 25 and 100, and in two strengths:

m. 1½ for Children
m. 3 for Adults.

Two palatinoids respectively represent the full daily dose of Vitamins A and D.

In Syphilology

BISOXYL

At the annual meeting of the British Medical Association this year it was reported that:—

"... bismuth was now adopted by practically all syphilologists throughout the world as a substitute for mercury. It was more efficient and less toxic than the older remedy."

The opinion was expressed that the maximum beneficial results are obtained when a watery suspension of a sparingly soluble bismuth salt is used—the bismuth content, the purity of the salt, the size of the particles and the stability and rate of absorption of the product being factors of the greatest importance.

Bisoxyl is such a suspension of a sparingly soluble bismuth salt; it is prepared from pure, finely-divided bismuth oxychloride, and special attention is given to the physico chemical requirements mentioned above. There is ample proof of the value of Bisoxyl, and the evidence in favour of its use has been supplemented again recently by investigations carried out at one of the large London hospitals. (*Lancet*, Nov. 16th, 1929, pp. 1034 and 1050.)

Elixir of

ENZYMES

Elixir of Enzymes is a palatable preparation of the proteolytic and curdling ferments that act in acid medium. It is recommended as an aid to digestion and as a stomachic stimulant and mild carminative.

Elixir of Enzymes is of especial service in correcting faulty protein digestion which is one of the principal causes of gastro-intestinal auto-intoxication.

Elixir of Enzymes is an excellent vehicle for exhibiting iodides, bromides, salicylates and other drugs that disturb the digestive functions. One dram of Elixir of Enzymes will carry 46 grains of potassium iodide or 45 grains of sodium salicylate or 17 grains of potassium bromide.

Intestinal Disinfection

RHEUMATOID ARTHRITIS

UNDER this name, several conditions which are ætiologically distinct are doubtless grouped together, and we are still far from a solution of the cause of the disease.

It is obviously impossible to restore in any marked degree mobility to the joints of the hopelessly crippled, but in the early stages much may be done to retard or stop the progress of the disease.

An eminent surgeon has directed attention to the rôle of chronic intestinal stasis and alimentary toxæmia in the production of the disease, and has emphasised the need for intestinal disinfection.

For this purpose nothing surpasses the use of Kerol Capsules. Kerol is a potent and non-toxic germicide which is unabsorbed from the intestine, so that the whole of its germicidal power is exerted upon the contents of the bowel.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Rational Prophylaxis

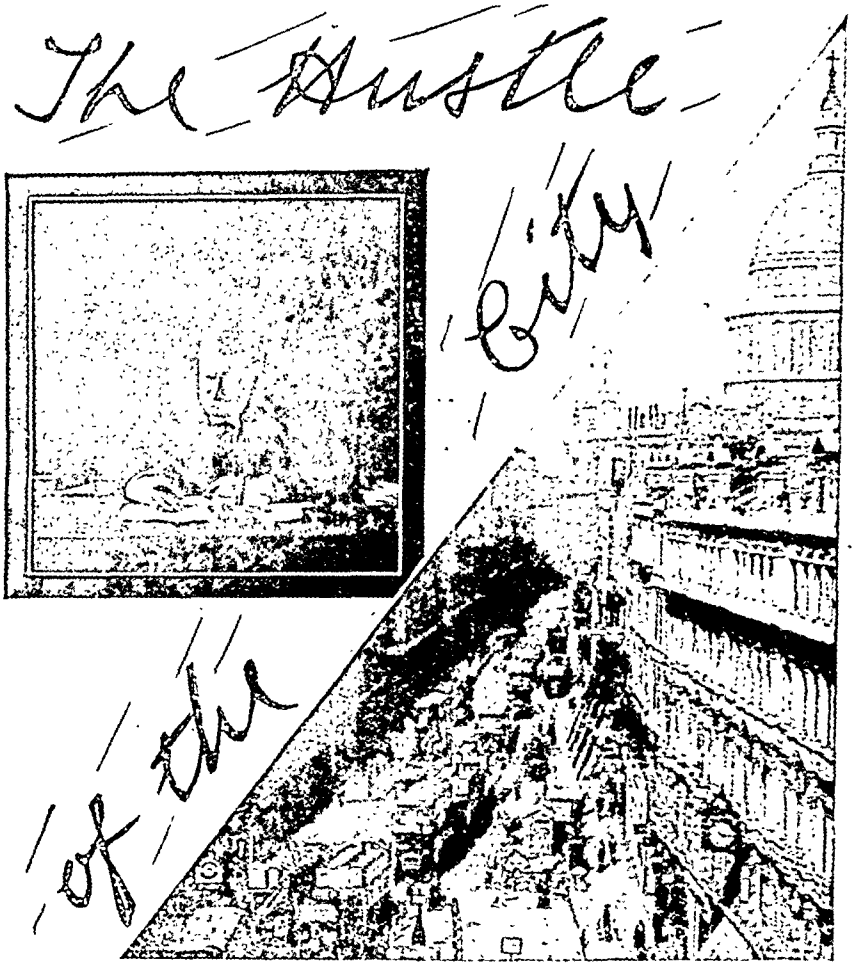
IT is clearly evident that the public health authorities now appreciate fully the importance and the possibility of reducing the incidence of seasonal epidemics.

Thanks to the advancement of medical science it is realised to-day that disease is largely a manifestation of a devitalised condition caused by inadequate nutrition and disregard of simple prophylactic measures. The ready availability of a product of the nature of Radio-Malt with its definite anti-infective and health-promoting properties makes rational prophylaxis universally possible.

The daily administration of Radio-Malt during Autumn and Winter prevents the draining of the reserve of natural disease-resisting power which is otherwise almost inevitable during the Winter.

RADIO-MALT

THE BRITISH DRUG HOUSES LTD. LONDON N-1



and its continuous nervous strain shorten the life of arteriosclerotic patients. General Treatment of high-blood-pressure cases can be advantageously supplemented by

"THEOMINAL"

Trade Mark Brand

Combination of Theobromine and "Luminal" brand of Phenyl-ethyl-malonyl urea.

"Theominal" reduces blood pressure, and, what is more important, improves the general condition of patients. It is indicated in Arteriosclerosis and its sequelae, Angina pectoris, Tachycardia, Climacteric disorders. "Theominal" is made up in 5 gr. tablets in tubes of 20, for dispensing purposes in bottles of 50, 250, 500 and 1000.

The Chronic

Often underlying the chronic condition is bowel stasis and irrational use of harsh cathartics.

Many chronic cases have been definitely benefited by a period of "habit time" education together with other rational treatment.

'Petrolagar' Brand Paraffin Emulsion affords a valuable aid to diet and exercise in bringing about a restoration of normal bowel movement, the effect being purely mechanical.

Petrolagar Laboratories Limited,

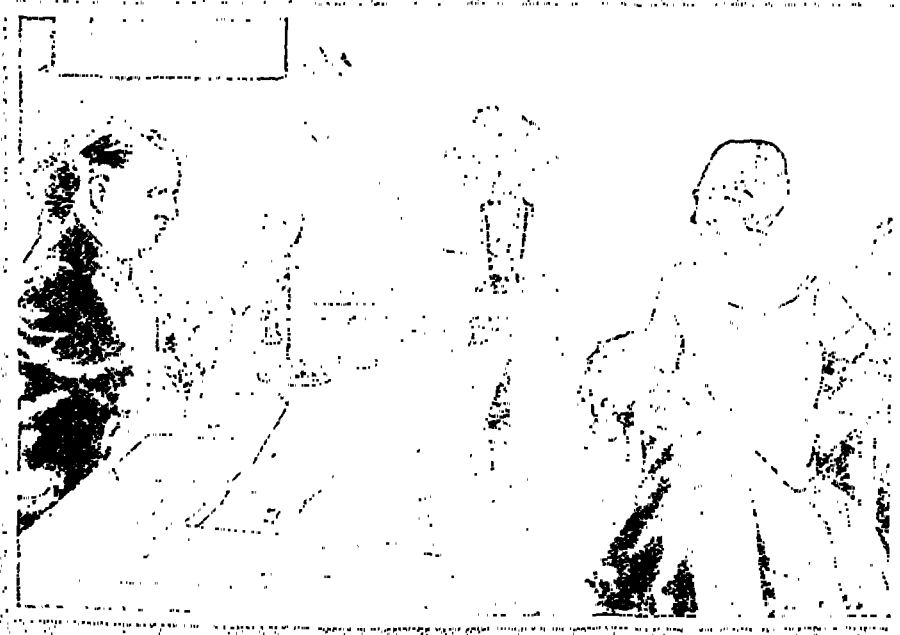
Petrolagar



National Committee for Promoting the Consumption of Norwegian Cod Liver Oil, Bergen, Norway

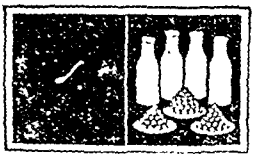
Ultra-violet radiation is sometimes tried to replace the lack of vitamins in food. It is not an economic way of attaining this result.

IN ITS REPORT FOR THE YEAR 1927—1928
the British Medical Research Council
STATES:

"The use of artificial light to supply only what the right food can give is merely wasteful. It commonly costs three or four shillings to give by light an effective supply of vitamin D that would cost less than a penny if given by the mouth in the form of cod-liver oil . . ."

Norwegian Cod Liver Oil abounds in natural vitamins. It is a natural food, supplying vitamins A and D, which is easily absorbed owing to its high percentage of glyceryl esters of unsaturated fatty acids. There is no efficient substitute for Cod Liver Oil.

A Teaspoonful of Norwegian Cod Liver Oil contains more Vitamins than



all the Butter and Milk any Individual can eat and drink in a Day

Calcium Deficiency in Women

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to secure adequate calcium retention.

The Practitioner says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

Rational Infant Feeding

The aim, in artificial feeding, is to produce as near as possible the equivalent of human milk, and therefore the most important constituent is the lactalbumin, because, apart from its protein value, it is responsible for breaking down the casein curd into minute, digestible particles. Albulactin is pure, soluble lactalbumin — the vital proteid of human milk — and when added to properly modified cow's milk it produces a milk mixture closely allied to human milk in composition and physiological effect. With Albulactin it is easy to meet every phase of infant feeding between the premature weakling and the normal robust infant.

The British Medical Journal says:

"There appears to be every reason to expect this preparation to prove of great value in the 'Hand feeding' of infants."

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO., Amsterdam, Holland.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

Messrs. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

A useful adjunct in the Treatment of RHEUMATIC AFFECTIONS

Reports received from Practitioners indicate that many cases of Rheumatic Affections have been successfully treated with Detoxicated Anti-Rheumatic Vaccine (Genatosan).

This vaccine now contains seven varieties of streptococci, including three new strains of osteotropic streptococci recently incriminated in the causation of rheumatism. Detoxicated Anti-Rheumatic Vaccine is an agent of great value in the treatment of acute and chronic rheumatism and rheumatoid arthritis.

A summary of recent discoveries regarding the bacteriology of Rheumatism appears in the Genatosan "Twelfth Vaccine Bulletin and Supplement." These booklets have been despatched recently to all Practitioners whose names appear in the Medical Register, and any Doctor who has not received them owing to change of address or other reasons is invited to write for copies which will gladly be sent free by the Vaccine Department of

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

Observations
ON THE
DIAGNOSIS AND TREATMENT OF FUNCTIONAL NERVOUS DISORDER.*

BY
T. A. ROSS, M.D., M.R.C.P.,
MEDICAL DIRECTOR, CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS, PENSHURST.

WHEN, as young men, we left hospital and went into practice most of us had the experience of encountering a great number of patients whose ailments did not seem of the same nature as those we had come across when we were students or resident hospital officers. Then the majority of the cases had well-marked physical signs, which helped us to place them in definite categories, whereas in many of our patients in private, though they presented a wealth of symptoms, there were few if any physical signs, certainly none of a gross nature, to corroborate these symptoms. It might, indeed, be said that the mainstay of many practices consists of those patients who do not present physical signs. They are not confined to one class of society, they are scattered throughout all, and I suspect there are plenty of them in the hospitals also, but they are not to be found *much in the wards; they are probably seen by the junior* out-patient physician, to whom they come again and again for the paper bearing the magic words "Rep. Mist."

The conscientious doctor with much industry examines them all over, to discover *what it is that is producing these* disabling symptoms; he passes in review their internal organs, their teeth, their eyes, their nasal sinuses, and what not; and so fine are the modern methods of diagnosis that some lesion, some departure from a normal ideal, can be found in most of *them, if enough care is taken.* Appropriate treatment is applied, and in the majority of instances great *improvement takes* place. After a period the patient has another illness without physical signs; again after examination and treatment improvement occurs, and this often enough goes on indefinitely. With some patients, however, the periods of improvement are short, later on *do not occur at all,* and much time and trouble is spent in trying to find out what is wrong, without avail.

I am very far from saying that because a patient exhibits *no physical signs* he is to be regarded as suffering from a neurosis; no doubt focal infections make people ill; and, still more, there are certain diseases such as encephalitis, disseminated sclerosis, cardiac degenerations, etc., in which physical signs may be absent for a time; but what I *wish to emphasize* is that the majority of patients who go in and out of illness over a long period, and who yet *present* no signs, are more likely to be suffering from a neurosis than from a physical illness, and that in all such the mental state should be investigated.

What is meant by *neurosis?* The definition which I should give provisionally is that a neurosis is that congeries of symptoms, whose name is legion, which depend on no physical change but on a failure to make mental adaptation to the *difficulties of life.* This definition does not exclude certain psychoses; but it emphasizes the point that the illnesses I wish to talk about are psychogenic.

Two attitudes are commonly taken up as regards the kind of case I have outlined. One, which is passionately defended by certain kindly men, is that these patients are ill physically, but that the illness is of a kind which we have hitherto *as a profession* ignored or slurred over; the illnesses are said to be due to causes like infection of the apex of a tooth, or of some other region of the body; to reflex causes, as from astigmatism; to intestinal or other intoxication; to failure in endocrine balance; to lack of vitamins, and so on. The ground on which these beliefs are justified is commonly that many patients are cured when these things are attended to; there is little other ground for them. It may be said that this ground is good enough; but not when we look into the history of the neuroses. Fifty years ago these patients were being cured by minor gynaecology, painting the cervix, putting in a pessary; later they were cured by the Weir Mitchell treatment; at another time by the Salisbury diet, just as effectually as they are now by the extraction of teeth or tonsils, or by the administration of polyglandular preparations. And now these older methods are little used. If they were as effectual as they were thought to be in the heyday of their youth why were they dropped, and how long will their successors last? There have been endless cures for these patients, and the one thing that the remedies must not be is old-fashioned; the one thing essential is that they shall be to some extent boomed.

This leads straightway to the other view held about these *people—namely,* that there is nothing wrong with them, that they are making a fuss, that they are imagining their symptoms. That this view is held by eminent members of the profession cannot be doubted. From time to time contempt for "poor neurotics" is poured forth in the journals from the highest quarters. The view is one which is a little *difficult to understand.* If a patient says he has a symptom, he either has it or he does not have it. If he *does not* have it he is an impostor, and it would be more honest on our part if we said so straight out, and did not take refuge in the subterfuge of calling the symptom "imaginary." I have tried frequently to get those who talk of imaginary symptoms to go all the way and say that the patient is a *liar,* but that far they will not go.

Now a third view is possible, and indeed if we consider the first group of doctors, those who hold that there is a physical cause for these disorders, and take the whole story of the cures together, we shall find a common factor. This factor is that both the doctors and their patients believed in the remedy, which explains also why the remedy must be in the fashion. If faith did good, there must have been want of faith in something to cause the illness. That is, the pathology of the illness is mental, but that does not in the least prove the view that it is imaginary.

A little ordinary observation would show us that there is a multitude of symptoms in everyday life which do depend on mental states, which are certainly not imaginary, and are equally certainly not dependent on physico-chemical alterations from the normal. In a person previously quite well fear may cause suddenly palpitation of the heart, tremor and paralysis of the limbs, pallor of the body, even diarrhoea; all these symptoms can be observed; there can be no question about their being direct consequences of the mental state. Less obviously, but in the personal experience of most of us, anxiety may give rise to a headache, failure of concentration, loss of appetite with indigestion, and poor and disturbed sleep. Let the fear go on for months and the symptoms get more and more prolonged, and there is a perfect picture of so-called shell shock. Let the anxiety be prolonged, and we get the fatigued, sleepless, dyspeptic person who cannot concentrate and who has a headache; the sort whom we label neurotic, and who is so common an occupant of every doctor's list. We begin then to see the possibilities of a non-physical pathology, of a psychopathology for the kind of recurrent invalids without physical signs about whom we have been thinking.

How are these patients to be recognized? For we have seen that mere absence of signs will not help us, and we cannot afford to wait for months to make a diagnosis; we are also to bear in mind that focal sepsis and such-like states may produce symptoms.

There are two criteria of great importance: one is the *attitude which the patient has towards his disease,* the second is the nature of the history. The non-neurotic person has a hatred of disease and not too much trust in doctors, especially when he is well. He is not proud of his disease; he makes light of it, he disobeys orders when he can. He is not wrapped up in it. There are some compelling diseases which may make anyone uninterested in anything else—abdominal catastrophes, acute pleurisies, severe fevers; but we are not likely to confuse these with the troubles of our neurotic patients. But the mentally normal man with early phthisis or early cancer is refractory to the idea that he is seriously ill—if he is or he is

*Made before the South Middlesex Division of the British Medical Association on October 9th, 1929.

neurotic as well as physically ill, for there is no reason why a neurotic should not have a physical illness. The neurotic, on the other hand, is immensely interested in his illness and takes the utmost care of it. If he has palpitation he is sure to think he has grave heart disease, and will accept and better any instructions he may receive about resting his heart; the true cardiopath who is not neurotic goes about his business with œdema up to his knees.

The history of the neuropath is characteristic, but there is a difficulty: it is not altogether easy to obtain it if one is hurried. A good deal of time is often needed to get it; the patient must be allowed to tell his story in his own way, and the doctor must be prepared to sit and listen. If this is attended to, the history is very easy to get. When it is obtained it will be found that the patient failed with unusual frequency to meet the ordinary difficulties of life in an adequate way, and that often he was prevented from doing so by illness, an illness which he may categorize frankly as a "breakdown," or which again may be concealed under some euphemism such as "flabby heart." The student did not get through his examination when he should, because he overworked, and got insomnia; or he foolishly went a walking tour a few weeks before the examination was due, dilated his heart, and so was unable to go up for it; the soldier who was particularly keen to go out to France, having been unduly detained in this country, got sunstroke a week before his draft left England, and has been giddy ever since. Another feature in the history is the inordinate gravity of common illnesses; when these patients get colds they are ill for weeks; influenza leaves debility for months or years; there are long periods of indigestion at times of life when affairs are difficult, and so on; and it will almost always be found that the present illness, which is the one the patient is clearest about in this preliminary history taking, arose when there had been a good deal of mental discomfort, stress, boredom, anxiety, grief, or the like. Something tipped the balance, as is seen most easily in the shell-shock cases. The patient had been living in terror for months; then he was blown up or buried and never got over it.

In the taking of the history there will emerge certain character traits which are also characteristic, and to one of the most important of these the name of narcissism may be applied. Narcissus, it will be remembered, was a youth who, perceiving his *own image* in a pool of water, fell in love with it, and stayed on for the rest of his life in that one spot gazing at it. All children pass through a stage of narcissism. Events are of importance solely because of the effects on themselves. The ideal normal adult should have escaped from this and should be able to look on the world objectively, without always considering how it is *going* to affect him personally. Through and through there is no such person, but I think we may say that we are grown up in so far as we have attained such a position. The history of the neuropath will show that he has hardly budged from the childish outlook. Intellectually he may have grown fully, but emotionally he has remained fixed, so that as his story is unfolded it is seen to be very much a tale of how he never got a chance; whenever by exercise of his industry or virtue things were prospering, some malign influence, some malign person stepped in and they went wrong. He may blame himself *too, but in* such a way as to give his listener ample opportunity to say "Oh, no, it was not your fault." And always that wretched health of his was giving way at critical times.

I do not say that this is not a portrait of most of us; but in these people it is more *manifest*, more the whole thing. Moreover, the really grown person does not readily tell his history; if he is pressed he will give a story of his life, but it will be a bald affair; he will tell us what parts of the world he was in at certain *periods*, will name the schools he was at, when he married, if he remembers the date, and so on. The neuropath will straight off pour out intimate details to a stranger, if only that stranger shows the slightest sign of being willing to listen sympathetically. He will usually say that he has *never told* this to anyone before, and we may feel flattered; but if we live in an institution we soon find that he has told a good *many* others. With some there is apparent stickiness; the phenomenon of garrulity is not so cunningly present, but that is usually because the patient is feeling that this listener will not listen sympathetically.

For the rational understanding and, as I think, treatment of the neuroses it is essential that the doctor should get to know this history one way or another, for one of the main things he will have to try to deal with is this self-centredness. I do not call it selfishness, for according to their lights these people may be quite unselfish in their acts. One of their bitter surprises with the world may well be that, having lived so unselfishly, they have been so terribly let down. Quite often, moreover, their deeds may be as good as those of other men. Two men go into a river to rescue a drowning child: one goes simply because there is the child who has to be fished out, and it is all rather a nuisance, but the job has to be done. That is a fully grown adult. The other thinks what will be thought of him if he does not go, or that he will get credit if he does go, or he gives himself credit for going. He is self-centred, not adult, neurotic.

All rational methods of treatment have as an aim that the patient should by going over his past become aware himself that he has been acting in a self-centred way. Psycho-analysis is nothing but this. The patient has not seen his acts in a proper—that is, fully adult—light; many of them he has forgotten altogether; he has forgotten them because if he reflected much on them he would be uncomfortable in his narcissism, and narcissism is to him essential; indeed, he is hardly aware that there is another mode of living. Psycho-analysis is, however, a thing that is outside our province; it is a thing wholly unsuited for general practice; it is a heavy weapon to be used rarely. But in general practice it is often possible by getting the history carefully to let the patient see for and by himself that his illnesses have come on, sometimes at any rate, because they helped him to solve a difficult situation, but that the solution itself was not worth having. It is possible, for example, to let him see from his own story that that examination which he deferred because of cardiac debility was one which he dreaded very much, and to let him see that dread may cause uncomfortable cardiac sensations about which at the time it was really rather helpful to be frightened; he had his reward, but it was not worth having.

It is clearly understood that the patient was unaware of what was going on. Why should he be aware? He was at the time anxious about the examination, and as he was anxious about something, he was liable to acquire these symptoms which anxiety produces—headache, poor sleep, loss of concentration, etc., which we have already considered. Whether, once they have started, they continue or not depends on the way in which they are regarded by the patient—and here is where our influence as doctors may make an enormous difference. It is common for the anxious mother of such a patient to ask the doctor whether the patient is not overworking, and it is common in my experience for the doctor to agree, when he has heard about headaches, insomnia, and so forth; and it is, I fear, rather common for him to hint that the symptoms are grave—especially the insomnia. The course of study is therefore suspended, not to be begun again till the examination is over. What is worse is that the patient is left with a fear that his brain will not stand hard work. He will not have been told this, but he naturally and legitimately infers that if he subjects it to hard work in the future he may become insane. I admit I see only those who have proceeded downhill after such an experience, and I may be biased, but I think it is common for such a person to be chary of ever using his brain very much again; for if he does he begins his work in fear, and that will, of course, soon reproduce all the symptoms; so that presently we get this person unable to read for more than the most absurdly short time—five minutes or something like that; if he tries to force himself he is stopped by symptoms. A few years ago I saw a lady of 57 who had seen an eminent oculist thirty years before. He had told *her casually not to strain* her eyes; and from that moment she had faithfully carried out his instructions. She had never read for more than ten minutes at a time, and that

only three times a day. Even that sometimes caused headache, and anything longer was followed by a very severe one. When she travelled her eyes were bandaged to shut out the scenery as it flashed passed at the rapid rate of fifteen miles an hour. After two or three reassuring conversations she was able to read all day without discomfort—but she had lost thirty years.

Another evil which accrues from such treatment is one of which the patient is not conscious, but which is nevertheless very potent. The patient has learned that he can escape from the disagreeable by illness. He will tend in future, and with each escape more and more, to use this method of settling all difficulties. He becomes one of those people whose nerves cannot stand this, that, and the other; of whom everyone has to be careful, who must not receive bad news, who must be saved all anxiety, for whom the world must be kept noiseless, who is, in short, a *perfect nuisance*.

I have drawn a picture of the patient who says he cannot sleep, and of the doctor who has regarded this loss of sleep as grave; but harm may be done in other directions. In parallel circumstances when symptoms were attached to other organs of the body—to the heart, the abdominal organs—there has been a tendency in some doctors to diagnose diseases that were not there, diseases sometimes which the doctor invented because he did not know what to say. In my younger days cardiac debility was one of them. He did not diagnose any known form of heart disease, for that could be contradicted; he said that at the time he was examining there was a weakness, and if later someone else should say that there was nothing wrong with the heart—well, he never said that the thing was more than temporary. The doctor himself had acted narcissistically; he had got out of a difficulty by some means other than facing it, regardless of the fact that someone else would have greater difficulties to face. For *this is true*—that every difficulty in this world which we ourselves shirk will have to be shouldered by someone else. *But to return to our doctor with a conscience*, who is far commoner; he too, as we saw, may err. He may begin to ponder why this lad or young woman cannot study like other people without disaster, and though he is not led by the will-o'-the-wisp of brain fag, lack of nervous energy, or some such thing for which there is as much evidence as there is for cardiac debility, he may begin a physical treatment. The patient is fitted with spectacles, her teeth are x-rayed and extracted, her appendix is perhaps removed, or her floating kidney is stitched up, though that is apt to come later in life. And during these investigations the important examination goes to the wall, and *again the patient* has escaped from a difficulty by means of illness; and when later on she wants to escape from another a fresh hunt round her body has to take place.

Now what should have been done? You must pardon me for being dogmatic. The first thing we have to consider is the value of these symptoms which the anxious student whom we have been considering presents. He himself is probably genuinely frightened by them. But are they of great importance? While they are present they are absolutely crippling; no one can do any mental work if failure of concentration is present, and no effort of will will overcome such failure. It is not, however, true that people cannot work because they have little sleep; there are many authentic accounts of brilliant brain workers who slept *little*; but no one can work if he is alarmed about want of sleep, if he feels that it is because he has worked so hard that he has become an insomniac, and that insomnia leads to *insanity*. Is it true that insomnia leads to insanity? There is no good evidence that it does; there is, I submit, no evidence that it leads to anything in particular unless the patient is anxious about it. We are in a vicious circle; anxiety about an examination caused insomnia, insomnia increased anxiety, and that in turn kept the insomnia in being. If we can persuade the patient that it is not so very serious, that it is at worst uncomfortable, we shall have gone a long way to stop the insomnia. The same may be said of every other anxiety symptom: if the patient has cardiac discomfort he will not move about for fear of straining his heart; if he has to move, the fear that he will strain it will bring on the discomfort; this increases the certainty in the patient's mind that there is a cardiac weakness, which increases the anxiety, and so on round and round.

When I was introduced to psychotherapy it was this point of anxiety about symptoms keeping these symptoms in being which was first brought to my attention; and while some patients seemed pleased to learn that there was no lesion, but only anxiety, I was surprised to find that most of them were annoyed, and often *seriously* annoyed, to receive a favourable opinion. Most of them had seen many doctors, and these might be put into three categories—the heartless fellows who frankly said there was nothing wrong and that the patient should pull himself together; the sympathetic who murmured that his nerves were not strong enough for the tasks of life, and who then gave bromide; the understanding men who said that there was a lesion, a cardiac weakness, an intoxication of some sort, who treated the peccant organ. The last two groups were liked because they told the patient that he must take *great care of himself*. *I think* I was put into a class of modified heartlessness; I did not tell him to pull himself together, but to listen to an explanation; on the other hand, I seemed to have acquired a rather subtle method of saying that there was *nothing wrong*. *It was no use* saying that anxiety was a something.

What I had not grasped in *these early days was that* most patients with functional symptoms are not prepared to take the consequences of being well. We have seen reasons why they may not be, but *the reasons may not* be manifest—not, I mean, to the doctor; they never are to the patient. He is blind to them. It is *therefore not* to be expected as a rule that improvement will follow the mere statement that there is no lesion, *even if the explanation* is given that anxiety is a satisfactory cause of the symptoms. But it is of the utmost importance that no positive physical diagnosis should be given, even if some lesion is present, unless the doctor is sure that that lesion will cause these symptoms. Suppose there is a mitral presystolic murmur and the symptoms are those of insomnia, loss of concentration, and fatigue, and suppose the heart is regular, the blood pressure normal, the patient has a good colour, is not short of breath, has no pulmonary signs—suppose, that is, that compensation is good; then it is certain that that heart is not causing these symptoms. But if any doctor suggests to that patient that it may be, a hundred others will not convince him to the contrary; and yet in our work we constantly find that lesions, where there is no certainty that they ever could cause symptoms of any kind, are being blamed for widespread disability, and that it is nearly impossible to get these beliefs shaken. Much, then, can be done by the practitioner not to increase and fix neurosis if he refuses to give even a tentative diagnosis in the absence of probability.

It is the young people whom it is necessary to be careful about. Old neurotics will probably remain neurotics; in them it is often difficult to distinguish between a neurosis and a degeneration, and it does not matter very much; but it is essential to be sure of the young. A hasty, ill-considered physical diagnosis may fix a neurosis for life.

If, however, the history has been listened to in the way described, the patient will reveal himself as a person who has habitually reacted badly to the calls of life; and a physician who has listened patiently to one of these people has thereby acquired great power over him. The patient feels that here at last is someone who has cared to try to understand, and from such a one he will receive the bitter draught of being shown where he has been acting wrongly. To please such a one he will see that he was shirking something, turning the symptoms of anxiety to account to get him out of difficulties; and with such a guide he will be able to see that nothing but misery can come out of such procedures. He will not like it at first, and he will probably need a good deal of guidance; but if these people are taken in hand in this way *it is* surprising how many will respond.

It will be urged that there is nothing very new in discovering that neurotic patients are self-centred, even if we use a new name; and it is true that by the time I see these patients they have usually been told very often that

they are self-centred. They have also been told that they are ill physically, in each case by a competent authority, and they do not know what to believe. They naturally have made some compromise, such as that they are weak-willed, an inborn defect for which they should not be held responsible, and which at any rate they cannot overcome. The secret of success lies in getting the patient to see things for himself, and telling him very little. He should be told that he has no lesion capable of producing these symptoms, but that the doctor has every reason to believe them to be there truly. That is nearly all the information he requires. He knows perfectly well that mental states cause bodily symptoms. He knows that disgust may cause vomiting; he knows that fear may cause palpitation, that horror may cause fainting, etc. He need only have his attention drawn to these things. If his history has been taken before any opinion is given, it can easily be shown that he was worse at difficult periods, at periods when he was more than usually anxious. It is a step from that for him to see that when, later on, there was the prospect of a difficulty, which illness could postpone, he sometimes fell ill, and so evaded the difficulty; and when he has grasped that he has done so habitually he will be less sure that he has been unlucky, and begin to think that he has not chosen the better part on important occasions, that he has acted pusillanimously, that he has tried to save his skin for the moment. There will be no need for anyone to use the world self-centred; he will see all that, all that it means without the word. I submit that this is something different from telling him.

If the patient has been led in this way to see that his illnesses have been mental in origin, and that his misfortunes have not been anyone's fault in particular, he may then easily develop a sense of guilt; the symptoms are his fault—somebody's fault they must be. To some extent this is, of course, a trait common to all of us, but in these patients the feeling is apt to be excessive. In a sense they always had this feeling more than other people; I do not think it is a creation of the treatment. It was repressed, and this implies that the patient himself was really unconscious of it. It is a phenomenon which needs some care in handling. It is a real sense of unworthiness, but a patient can easily use it as a something with which to beat the doctor, and make him sorry that he ever started to unravel the patient's mind. There are many times when he is excessively angry with the doctor for depriving him of the symptoms out of which he frequently derived benefit; there are many other times when he sees that this doctor has been his greatest friend—to both attitudes we must preserve a certain aloofness. Do not set much store by the praise that will from time to time be heaped on you by these patients, and you will not be much upset by those other occasions when they are not only blaming you to your face, but gossiping behind your back.

We shall find after a short time of treating a patient in this way that though he may still report symptoms, our conversations are, on the whole, not about symptoms but about mental affairs—about frustrations of desire, about guilt for shortcomings, about difficulties that require to be met, about the best ways of meeting them. The danger that is to be then avoided is that we should become too much the person without whom nothing must be done, whereas our aim is that these people should learn to stand on their own feet. While at first we may have to point out what their course of action should be, later we shall have to let them know that they themselves must settle their own problems. For example, the modern young lady has nothing to do at home, and leads there a life where every hour has to be provided with spurious occupation, which is of no value to anyone, and therefore merely a pandering to her self-centredness. When she makes the discovery that her business is to be helping somehow in the work of the world, she would like to be told what to do. Personally I never try to find out. If I selected a job for her she would soon let me know that it was unsuitable. I tell her to read advertisements, and that downstairs she will find the current number of a magazine devoted to women's occupations. My business is not to settle anything for her, but to let her feel that so long as she remains somebody to be amused she is not likely to keep well.

Two corollaries and I have done. The first is that there are an enormous number of people going about suffering from minor illnesses which are called indigestion, gastritis, debility, headache, eyestrain, brain fag, and many other names, who are suffering from neurosis and whom a comparatively simple therapy would cure. Some are no longer in need of an illness to help them out of difficulties—that phase has passed. They can be cured by the simplest explanation. They have remained ill because fear was put into them. They have got lost in a fog and are glad to be taken out of it. They are the people who, to our shame, are cured by Christian Science, by Coueism, and other unscientific remedies. There are, of course, others who will need the training in character outlined above.

The second point is that we have envisaged neurosis not as an illness but really as a badly developed personality. The thing began in childhood, though its manifestations may not have called for medical help till much later. If this is true our re-education can never begin too soon; and indeed it should be pre-natal. It is the parents who start these things, not, as I think, by heredity so much as by example. If heredity is a factor, then the neurotic parents should be all the more careful about what they do with their children, above all what example they show them. The mother who goes to bed with a headache because the cook has given notice is not only doing something bad for herself, she is teaching the children in the worst way possible how difficult situations should be met. The parents who are taking undue physical care of their children, who are petting them, who are unkind to them, who are, in general, silly with them, are a good deal under the eye of the family doctor, and I think it is very much in his power to sterilize the seeds of neurosis at the beginning.

In conclusion I feel that I have been saying what most of you know and practise; those who do not are not the ones who attend these meetings. If I have been too elementary I apologize, but in my own practice I seem to see the hand of those who do not practise these things. The neurotic sees many doctors, and he unfortunately clings to the teachings of the bad ones.

CONSTIPATION: ITS NATURE AND DIAGNOSIS.*

BY

GEOFFREY EVANS, M.D., F.R.C.P.,

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL.

IT is with a feeling of some diffidence that I offer these remarks on a subject so commonplace as constipation. It would have been an easier task to deal with certain aspects of the disorder, such as its varieties, its causation, or its treatment; but it will be my object to discuss chiefly constipation itself, its nature, and its diagnosis, because these are matters of first importance and some difficulty.

For general purposes, though difficult to apply to a particular case, constipation may be defined as a condition of undue delay in the passage of food residues through the large bowel. It has been more accurately defined by Dr. Hurst as a condition in which none of the residue of a meal, taken eight hours after defaecation, is excreted within forty hours.

Symptoms of Constipation.

These fall into three main groups, and it is by the appearance of one or more of these symptoms that a person recognizes the fact of constipation in himself, or, in other words, diagnoses his own complaint.

The first group of symptoms is directly related to the disorder of function of the large bowel itself, and they are as follows:

1. Regularity of defaecation. The best regulated bowel empties at a certain time once or twice in every twenty-four

* An address to the Devon and Exeter Medico-Chirurgical Society, October, 1929.

hours.* Less frequent evacuation, such as once in forty-eight hours, may be normal, and it is possible in a particular case that an evacuation three times in twenty-four hours is physiological. To the extent that it is a matter of convenience it is under the control of the will, and to the extent that it is a matter of habit it is dependent on a series of reflex mechanisms.

2. Completeness of evacuation. This is perhaps even more important than regularity of evacuation. The rectum is usually empty in a healthy person, and the passage of faeces into it gives rise to a sensation of fullness in the perineum and a desire to go to stool; if it does not empty completely with defaecation there is a remaining sensation of fullness, or of incompleteness of the action, which vitiates the sense of satisfaction that accompanies the perfect performance of physiological function.

3. Hard stools, and difficulty or discomfort in passing them. This is generally accepted as evidence of constipation by a healthy person, but if it is occasional and the evacuation is complete it may occur without undue delay.

4. The size of the stool. Most people, without actual inspection of the faeces, have a general idea as to whether or not the evacuation is adequate in bulk; this criterion may be fallacious because it is dependent partly on the size of the stool and the effort with which it is passed.

5. Abdominal discomfort. A sense of distension (or pain) in the abdomen, more particularly felt horizontally just below the level of the umbilicus, a sense of discomfort in the left iliac fossa, or a sensation of fullness or pressure behind the symphysis pubis, are symptoms which may arise from a delay in the passage of material through the bowel; they may equally be due to the accumulation of flatus.

The second group of symptoms is due to a disturbance of function of the digestive tract apart from the large bowel. These symptoms are chiefly gastric, and perhaps in part hepatic; they are a loss of appetite, nausea, a feeling of biliousness, acidity, heartburn, and a bad taste in the mouth, particularly on waking in the morning.

The third group of symptoms affects the body as a whole, or systems other than the digestive tract; they are headache, physical and mental inertia, a sense of fatigue and mental depression, and other more remote symptoms, such as precordial discomfort, palpitations, and rheumatic pains in the thighs, which symptoms the patient, from past experience, has learned to associate with constipation.

In this selection of symptoms of constipation no reference has been made to a large and varied group of symptoms generally attributed to intestinal toxaemia, both because constipation should be considered, in itself and in its symptomatology, as a disorder simply of neuro-muscular activity, and because it is uncertain that constipation alone is responsible for any state of toxaemia. It might be argued that some of the symptoms previously named are toxic in origin and not reflex, and that the headache, for instance, is surely a toxic phenomenon. This explanation is unlikely, however, because the headache passes very quickly, or at once, with a complete evacuation; and Alvarez has shown that a headache may result from distension of the rectum.

The Necessity for Accurate Diagnosis.

In regard to most symptoms of disease a man generally goes to his doctor for a diagnosis; but he is inclined to regard his bowels as peculiarly his own concern and to deal with their disorders by himself, sometimes helped by the advice of a friend or a friendly chemist. If he consults his doctor at all, the diagnosis is already made, and he tells his doctor that he is suffering from constipation and wants treatment for it. Now if a man goes to his doctor and says his kidneys are bad, the doctor is sceptical of the diagnosis, and says to his patient, or thinks to himself, "What do you know about your kidneys? Tell me your symptoms; let me examine you; leave the diagnosis to me." But if a man goes to his doctor complaining of constipation, the diagnosis is taken on trust, and often even without inquiry as to the history or symptoms of the complaint, and treatment for constipation is prescribed forthwith. I can best make my point by quoting an extreme case of supposed constipation.

The patient was a girl, aged 14, whom I was asked to see a few years ago. Having heard that the girl had been obstinately constipated all her life I advised her admission to a nursing home for observation. The following day her mother asked me how I intended to treat her daughter, and in reply I asked for a little time to consider the case, because I was not yet sure of the diagnosis. Her mother was taken aback, and said there was no doubt of her being constipated, because her bowels had never acted without an aperient since birth. I prescribed a low-residue diet to prevent distension, a teaspoonful of paraffin oil at bedtime to prevent the accumulation of hard faeces, kept the child in bed, and awaited events. At the end of two days of inaction the bowels acted, and continued to do so regularly and completely; meanwhile the diet was increased, the paraffin discontinued, and the patient given her liberty. When the mother was told that her daughter was not constipated, and probably never had been, that in fact the diagnosis of constipation had been wrong, she explained that her husband was a martyr to constipation. She was determined, she said, that her daughter should never suffer like her husband, and so had given laxatives regularly from birth; on any day that the bowels had not acted she had given the child a laxative. She was content with the explanation that the bowels had never had time to act naturally, because she had kept them too empty, and all was well.

Physiology of Peristalsis.

Just as a knowledge of anatomy is essential to the recognition of variations in structure, so is a knowledge of physiology essential to an understanding of disorders of function. Alvarez has put the matter simply when he asks the question, "Why does food go down the bowel?" and the same question first occurred to me when I saw a patient suffering from anorexia nervosa, whose food regurgitated up her oesophagus and poured out of her mouth as easily as it had previously been swallowed. Death ultimately resulted from slow starvation, and at the necropsy no change in structure was discovered to account for the remarkable reverse peristalsis which was exhibited during life. To say that food passes downwards as a result of peristalsis simply begs the question, for it does not explain why the food passes downwards instead of upwards, nor does it explain reverse peristalsis in normal digestive activity.

The first explanation offered by physiologists depended on certain experiments on animals in which stimulation of the bowel at a point caused contraction above and dilatation below. The difficulty of repeating this observation in different animals, and even in the same species of animal, under the best experimental conditions, threw doubt on the validity of what had become known as the myenteric reflex. Another explanation of peristalsis is in terms of nervous control; it has been suggested that the control of peristalsis rests in collections of nodal tissue situated at intervals in the wall of the digestive tube, and that each node sets the pace for and controls the rhythmical activity of a certain section of the tube.

It is tempting to compare peristalsis in the intestine with the mechanism of contraction as we know it in the heart; but the anatomical and physiological facts are not yet available, and it is not yet agreed, for instance, that nodal tissue exists in the walls of the digestive tube. Meanwhile a more convincing theory, the gradient theory, is being worked out by Dr. Walter Alvarez.[1] Alvarez has shown that proximal segments of the small intestine are more irritable than distal segments, and he explains the passage of food residues downwards in terms of this graded irritability, since material would tend to pass from more irritable to less irritable segments. He has also shown that there is a gradient of rhythmic contraction; in the case of the rabbit the rate of rhythmic contraction is twenty times per minute in the duodenum as compared with ten times per minute in the lower ileum, and he says that by observing the rates of contraction of short excised segments he can recognize which are proximal and which are distal. Further, there is evidence of an underlying metabolic gradient—in other words, the rate of anabolic and oxidative processes in the bowel is more rapid in proximal than in distal segments. To what extent the gradient theory can be applied to the human colon is still uncertain, but there is reason to believe that the tone of the rectum and sigmoid is higher than that of the colon immediately above, and Alvarez has suggested that this

prevents faeces packing up against the sphincter ani previously to their expulsion.

We owe much of our knowledge of the movements of the normal colon to Dr. Arthur Hurst,[2] who has published many original observations on the subject during the past twenty-two years. The passage of food residues through the colon is chiefly effected by a sudden contraction of the colon as a whole, as the result of which the contents of the bowel are moved forward in a single mass for a distance of twelve inches or more in a few seconds. This movement is termed mass peristalsis, and the chief stimulus to its production is eating a meal. The co-ordinating mechanism is presumably the gastro-colic reflex first described by Hurst. Defaecation is normally initiated by a voluntary act, by which the intra-abdominal pressure is increased by contraction of the muscles of the abdominal wall and depression of the diaphragm, and at the same time the anal sphincters are relaxed. The call to defaecation is a sensation of fullness in the rectum due to its rapid distension by faeces which pass into it from the pelvic colon. By the voluntary effort to empty the bowels the intrarectal pressure is increased and an involuntary movement of mass peristalsis in the large bowel is set in motion by a reflex mechanism whose centre is situated in the lumbo-sacral region of the spinal cord. The whole colon appears to be involved in this movement of mass peristalsis which accompanies the evacuation of faeces. The contents of the caecum and ascending colon are moved into the transverse colon or beyond; the contents of the distal portion of the transverse colon are moved into the descending and iliac colon, and after the emptying of the rectum and pelvic colon they are passed out in turn through the anal canal.

This in barest outline is a brief account of the mechanism of the passage of food residues through the intestinal tract. I have purposely omitted reference to other neuro-muscular activities, such as local contractions of the bowel wall, variations in the tone of the circular and longitudinal coats, and other forms of peristaltic activity of the colon, including reverse peristalsis. I visualize the digestive tract with its own independent activity in terms of the gradient theory put forward by Alvarez, and the co-ordination of its activities by the reflex mechanisms studied by Hurst, the centres of which are situated in the spinal cord.

The activity of the higher centres which are involved in eating and swallowing food, and in defaecation, cannot, however, be left out of account even in such a skeleton description of bowel movements as this. The reflex mechanisms so far referred to are congenital or inherited reflexes. The researches of Professor Pavlov[3] have shown the importance of acquired or conditioned reflexes to be no less than that of unconditioned reflexes. Conditioned reflexes are the basis of what are commonly called habits, and are largely concerned in much of the activity which was previously regarded as instinctive. Now that we know that even a puppy's choice of food is partly an acquired or conditioned reflex (though its potentiality to acquire a conditioned reflex may be inherited), we shall hesitate to speak of the natural or normal food of man, and we shall hesitate before making an attempt to alter the habits of a healthy man. Not only does a study of Pavlov's work make it easier to understand why some people eat one kind of food and another people another kind, but even the man whose bowels act daily at 9.45 a.m. with such regularity that he can set his watch by their movement is no longer a remarkable phenomenon, but rather a simple example of a conditioned reflex whose effective stimulus is the passage of an interval of time.

The Rate of Passage of Food Residues.

Constipation has been somewhat academically defined as a delay in the passage of food residues through the digestive tract, and therefore to make the diagnosis of constipation we must have some measure of the normal rate of passage of intestinal contents. In many normal people carmine taken before breakfast one morning is evacuated with the stool passed after breakfast the following morning, and it occupies the last part of the stool. Seeing that, with a stomach which has emptied four hours after a meal, the ileum is empty five to six hours later, it follows that much of the food taken after the carmine is still in the large bowel. When defaecation is efficient and complete the contents of the colon from the splenic flexure to the rectum are evacuated more or less completely. Hence under normal circumstances the caecum, ascending colon, and probably the proximal two-thirds of the transverse colon, always contain food residues.

According to Hurst's observations, the length of time taken by a meal to pass through the digestive tract varies from nine to thirty-three hours, depending on the relation of the hour of the meal to defaecation. Thus, part of a meal taken nine hours before defaecation may reach the distal end of the transverse colon by the time of defaecation, and be carried out through the rectum by the mass peristalsis which accompanies the act. If the bowels act once in twenty-four hours the rest of the meal will remain in the bowel for a further twenty-four hours. During this time it will be carried presumably in successive movements of mass peristalsis past the splenic flexure through the descending colon and iliac colon (which lengths of the large bowel tend to remain empty of food residues) into the pelvic colon, where it collects. If any passes from the pelvic colon into the rectum, it should normally give rise to a desire to empty the bowels. Food residues, however, from successive meals are mixed together in their passage through the digestive tract, and some days may elapse before the whole food residue of one meal is evacuated. Carmine can generally be recognized in the faeces of two days, and the barium of a barium meal remains, as traces at least, for two or three days.

Alvarez has tested the rate of passage of small glass beads 2 mm. in diameter through the bowel in normal subjects with good digestion. In a series of experiments on eight healthy young men there were two who passed 85 per cent. of the beads in twenty-four hours, but most of them took four days in which to get rid of 75 per cent., and there were some who passed only 50 or 60 per cent. in nine days. He notes that those with slower rates usually had well-formed and well-digested stools, but some of the subjects had a tendency to constipation. Seeing that these observations show a greater delay in the passage of material through the bowel than the accepted normal from *x*-ray observations, 60 grams of barium were given in milk to a number of students; their stools were collected, and the drug was recovered quantitatively. It was found that 75 per cent. of the drug was passed by the third day, and after that there was a slow excretion lasting several days.

Whatever difference there may be between the actual figures in different series of experiments, there is no doubt that, normally, food residues take considerably more than twenty-four hours to pass intact through the digestive tube, and as we know that the stomach and small intestine normally empty themselves completely, it follows that in ordinary circumstances food residues remain for a length of time in the colon.

In view of the functional activities of the colon, this delay in the passage of material through it is to be expected. Thus, apart from the mass peristalsis already described, a characteristic feature of the colon musculature is its sluggishness; Alvarez says that excised bits of colon muscle generally have a slow rate of contraction, and the parts proximal to the middle of the transverse colon are very tolerant of distension. In addition to being a passage for food residues, its important function is the absorption of water; it also absorbs some of the final products of digestion; it is an excretory organ for the salts of heavy metals, and one other function, which is important from our present point of view, is its capacity to act as a reservoir for the digestion of cellulose by bacterial fermentation. It is curious that those people who particularly advise the ingestion of large quantities of cellulose by their fellow men should be insistent on frequent evacuations of the bowel, and the hurried transit of food residues through the digestive tract.

It is a common opinion at the present time that the bowels should be empty, but with this knowledge of digestive function the medical profession is in a position to assure the public that the bowels should normally contain food residues, and should not be empty. In order to make this point perfectly clear to those who have an obsession about keeping their bowels empty, and who, to achieve this end, take laxatives regularly, I am in the habit of saying that it is better for the bowels to be full than

empty. I believe it is impossible to empty the colon completely, and that because of the inability of its walls to collapse (as can those of the small intestine and rectum), the emptying of the colon of solid material necessarily leads to the accumulation of flatus. It is simple to understand how this misconception about keeping the bowels empty has arisen. There are two parts of the digestive tract which are usually empty—namely, the gullet and the rectum. If anything sticks in the gullet it is a cause of acute discomfort. When solid material or gas reaches the rectum, and thereby distends it, it should lead to a desire to evacuate it. When evacuation is ineffective or incomplete, distension of the rectum with faeces gives rise to local discomfort, as well as more distant effects, such as headaches, a sense of fatigue, and other symptoms. These pass away, as it were by magic, with the emptying of the rectum, perhaps after taking a purge. And so the average man, ignorant of physiology, confuses his rectum with his colon, and comes to the conclusion that a state of health is best achieved by as complete an emptying as possible of the whole bowel.

The Clinical Diagnosis of Constipation.[4]

It follows, therefore, that—as in the case of other diseases, whether functional or organic—we cannot rely on our patient's diagnosis of his own disease. A careful history and review of the symptoms may lead to a provisional diagnosis, but the diagnosis can only be established by clinical examination. The first essential is to establish the fact of constipation as the primary disorder, and assuming that this is done by the exclusion of disease elsewhere in the body, and by the exclusion of demonstrable organic disease in the digestive tract itself, the accurate diagnosis of constipation on an anatomical and physiological basis is approached.

On an anatomical basis constipation is recognized as occurring in two forms. In the first, known as colon constipation, there is an undue delay in the passage of food residues through the colon. In the second, which is known as dyschezia, there is a failure in the mechanism of defaecation. Dyschezia may be further distinguished as due, on the one hand, to a failure in the function of the rectum to empty, and, on the other hand, to a failure in the function of the pelvic colon to empty in defaecation.

On a physiological basis colon constipation is divided into three forms: (*a*) a general undue delay in the passage of food residues through the colon, which may be termed sluggish colon; (*b*) an over-irritable or spastic state of the colon, which is termed spastic constipation; (*c*) an atonic condition of the colon, which is rare, and which is termed atonic constipation.

These several varieties of constipation can sometimes be diagnosed on the clinical history. Thus, a patient suffering from rectal dyschezia will complain of a sense of fullness in the rectum, of a sensation of being unable to empty the rectum completely, of piles, pruritus ani, or other symptoms of rectal congestion. Sigmoid dyschezia may be suggested by discomfort in the left iliac fossa, due to stasis and congestion in the iliac colon, discomfort and a sense of distension immediately above the pubes, or in some cases to an alteration in the action of the bowels, the patient noticing that in defaecation there is a single action which is due to the evacuation of the rectum, but that there is no closely following action which results from a complete emptying of the pelvic and iliac colon. In both these cases the stools tend to be hard and passed with difficulty.

In colon constipation there is a sense of general abdominal distension, and complaint of many of the symptoms referred to in sections 5 and 6 of the paragraphs describing symptoms of constipation, at the beginning of this paper.

Spastic constipation is one of the most obstinate forms of the complaint. It is associated with nervous exhaustion; it is accompanied by abdominal discomfort, which is chiefly felt on the right side of the abdomen, and which frequently amounts to actual pain, making the differential diagnosis from chronic appendicitis and cholecystitis a matter of considerable difficulty. Those who suffer from this complaint frequently experience a feeling that food residues do not pass further than the left hypochondrium, or at any rate never reach the rectum. They have generally acquired the habit of taking laxatives regularly every night at bedtime, and, having tried paraffin oil, agar preparations, and senna pods without success, they have come to rely on phenolphthalein, cascara, or vegetable laxative. On account of increased tone in the rectum and sphincter ani their stools, when formed, are small and round, like a lead pencil, or flat and narrow, sometimes described by the patient as like a tape; generally, as a result of taking laxatives, their stools are loose.

Physical Examination.

Both with a view to establishing the fact of constipation, and with a view to the accurate diagnosis of its variety on an anatomical and physiological basis, the patient who complains of obstinate constipation is advised to take a low-residue diet, one or two drachms of paraffin oil every night at bedtime, to stop all laxatives, and to report again at the end of seventy-two or ninety-six hours. At the same time he is instructed to make an effort to empty his bowels three-quarters of an hour after beginning breakfast, at some time between 6 and 9 o'clock at night, and at any time in the day that he feels the call to go to stool. The low-residue diet is prescribed with the object of preventing abdominal distension, in case the patient should be suffering from spastic constipation. The paraffin oil is to prevent the accumulation of very hard faeces in the rectum and pelvic colon, in case the condition should be one of dyschezia. Laxatives are stopped to allow of the diagnosis of the fact of constipation, and of its variety when present. The bowels having been emptied by laxatives, it naturally takes twenty-four hours for a normal food residue to collect, and another twenty-four hours before this food residue is an efficient stimulus for evacuation; indeed, owing to the excessive stimulus to which the bowel has become accustomed by the habit of taking laxatives regularly, it may be a further twenty-four hours before a normal stimulus is effective in provoking peristalsis. The instruction to make an effort to empty the bowels three-quarters of an hour after beginning breakfast is given with the object of allowing the gastro-colic reflex time to act, and in case, as a result of some conditioned reflex, it should have become a habit of the bowels to respond to a gastro-colic reflex at a later time in the day, the patient is advised to make the additional effort between 6 and 9 o'clock at night as a regular habit, and at any hour of the day if he feels the least inclination. At the same time the patient is advised to get up early enough in the morning to have plenty of time to wash and dress before breakfast, time to enjoy his breakfast, and time for defaecation before starting the day's work; he is also advised not to strain at stool, the gastro-colic reflex and defaecation reflex being relied on for normal evacuation.

Having been given these instructions the patient reports again at the end of seventy-two or ninety-six hours, and it may then be possible to determine the fact of constipation, and, if constipation is present, its variety, by clinical examination. Rectal dyschezia will be diagnosed by finding the rectum full of faeces; sigmoid dyschezia may be diagnosed by the same means, though in some cases where the pelvic colon is out of reach of the examining finger, the accumulation of faeces in it may be a matter of inference rather than one of demonstrable fact. In both kinds of dyschezia there is frequently a fullness, a hardness, or tenderness of the iliac colon. When the condition is one of sluggish or atonic colon the whole abdomen has a doughy feel, or the colon may be distinctly palpated as a large, sometimes rather tender, firm, or doughy mass, occupying the position of the ascending, transverse, and descending colon. In a typical case of spastic constipation the rectum and sigmoid are empty, there may be spasm of the sphincter ani, and so much contraction of the rectum that it fits the finger like a glove; the iliac colon may be felt like a cord tightly contracted, in contrast to the caecum and ascending colon, which are full, firm, and tender, suggesting chronic appendicitis, the tenderness, however, being more diffuse. When there is tenderness of the hepatic flexure the differential diagnosis is from disease of the gall-bladder and right kidney, and in some cases the reflex spasm of the pylorus and hyperchlorhydria suggests the diagnosis of peptic ulcer.

Other points in the clinical examination of the case, such as the general condition of the patient, his physical form, and the state of his nervous system, assist in the diagnosis, but the differential diagnosis of the varieties of constipation is one of considerable difficulty, and can only be made in some cases by *x*-ray examination.

Radiographic Diagnosis.

In order to avoid the description of the radiographic appearances in the different forms of constipation a series of films illustrating the several varieties of constipation was shown. Not only is radiographic evidence useful in confirming, or otherwise, a clinical diagnosis, but it is of particular value in excluding certain forms of organic disease, such as diverticulosis, early carcinoma, and other forms of organic disease which may be difficult to exclude with certainty by clinical examination; it is also invaluable in the accurate diagnosis of those cases in which more than one variety of constipation is present at the same time—as, for instance, the coincidence of spastic constipation and rectal dyschezia.

Treatment of Constipation.[5]

The first object of treatment is to obtain a regular action of the bowels with the passage of a formed stool. Just as mental depression and emotional distress are responsible for constipation, and just as fear and fright may cause diarrhœa, so constipation is itself responsible for a sense of depression and fatigue, and the constant passage of loose stools over a period of years is the cause of nervous exhaustion, and its cardinal symptom, fear. The second object of treatment is to secure a regular and complete evacuation of the bowels by the regulation of habits of life and food. The importance of habits in allowing an opportunity for the various reflex mechanisms concerned in bowel activity to have an opportunity for their action has already been alluded to. The need for caution in advising anyone to change his dietetic habit has already been indicated; at the same time it is obvious that rectal dyschezia requires a full-residue diet and a soft stool to assist complete evacuation of the rectum, while an irritated condition of the colon, such as is present in spastic constipation, must be given rest by the prescription of a low-residue diet, which will save the tired and irritated bowel from unnecessary stimulus. The third object of treatment is to find a drug, where drug treatment is necessary, which will promote the passage of a formed stool without pain or discomfort, and one which can be used without variation, if necessary for years on end, in minimal but adequate dosage. If the laxative employed requires changing from time to time it is evidence that it is unsuitable for its purpose. Remembering always that the movements of the colon are considerably more sluggish during the night than during the day, it is important that it should not be unduly stimulated by an evening laxative. Excessive colon activity, due to taking laxatives at night, is a common cause of insomnia, and there can be little doubt that almost as much disease and distress of a low-grade and chronic type is caused by the habitual use of laxatives as results from the abuse of alcohol and other stimulants.

In dealing with disorders of the bowel, whether of functional or organic nature, the result of bowel activity must at least be seen, if not examined in a more detailed manner. No man would venture an opinion on the condition of the kidneys without examining the urine, and no man can give a final opinion on the condition of the bowels without seeing the stools. Apart from the completeness of digestion of food residues, which can be largely judged by the inspection of the stools, and apart from the presence of mucus, pus, and blood, which may be an indication of organic disease, the size and shape of the stool provide an indication of the state of tone of the rectum and anal sphincters; the bulk of the stool gives some idea of the patient's diet and rate of passage of food residues through the bowel, and the fact of the last part of the stool being soft or semi-solid is a good criterion that evacuation has been complete.

POSITION OF SURGERY IN THE TREATMENT OF GASTRIC AND DUODENAL ULCERS.*

BY

H. H. RAYNER, M.B.Vict., F.R.C.S.,

SENIOR ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY.

A SUMMARY of the statistical records of gastric and duodenal ulcer cases dealt with in the Manchester Royal Infirmary during the past four years may usefully introduce this subject. It should be explained that these records are carefully compiled, and it may be taken that the diagnosis of ulcer has been verified so far as the circumstances have permitted.

1. The average number of admissions per year (1925-29 inclusive) of non-perforated gastric and duodenal ulcers exceeds 400, and of these some 70 per cent. are admitted (directly or by transfer from the medical wards) to the surgical wards. Some 60 per cent. of the ulcers are duodenal or pyloric, and the remainder gastric or prepyloric.

2. The average number per year of perforated ulcers is 135, of which 75 per cent. are duodenal. The mortality rate for perforated duodenal ulcer cases is 12 per cent., while that of the perforated gastric ulcer is 33 per cent.

3. The frequency of haemorrhage as a complication of ulcer cannot be gauged from the hospital statistics, because in the group of cases labelled haematemesis or melaena (or both) there must be a few in which the haemorrhage is due to conditions other than ulcer; furthermore, it must be remembered that only a proportion of the cases of haematemesis are sent to hospital for admission as urgency patients; whilst as regards perforations in the population served by the hospital, almost all nowadays will be sent in for the necessary operation. However, it is worth noting that some 40 cases of haematemesis are admitted each year to the medical wards, and the mortality of these under medical treatment is about 10 per cent.

The figures I have given show that in this hospital—on the staff of which medicine and surgery are pretty equally represented—surgery is still employed in the treatment of the majority of cases of gastro-duodenal ulceration without including the perforated ulcers. I do not suggest that this proves the value of surgery. I merely draw attention to the fact.

So far as the perforated ulcers are concerned, there can be no doubt about the nature of the treatment, and it is gratifying to see the great improvement in the results during the past twenty-five years, though the mortality in the gastric ulcer group still leaves much for the surgeon to improve upon. The improvement in the main is due to the earlier recognition of the catastrophe—it is now quite common for these cases to reach the surgeon within an hour or two of the occurrence of perforation; better surgical technique, too, accounts for some of the improvement. In regard to the latter it is interesting to note the difference of opinion among surgeons as to the scope of the operation for closure of a duodenal ulcer perforation. Some strongly advocate the performance of gastro-enterostomy at the time of the operation for closure of the perforation, unless, of course, the patient's condition is so poor that nothing beyond the essential minimum of closure of the perforation is permissible. It is claimed by these surgeons that the immediate and remote results are better if gastro-enterostomy is done at the time; other surgeons content themselves with closure of the perforation and cleansing of the peritoneal cavity, and only practise gastro-enterostomy in the exceptional case in which there is already pyloric stenosis, or in which stenosis is considered extremely likely to follow on the closure of the perforation owing to the distortion and narrowing of the duodenal lumen which this step sometimes entails.

I do not myself perform a gastro-enterostomy unless pyloric stenosis is present, or apprehended as very likely to follow, and in a series of my own cases, 30 in number, I performed a gastro-enterostomy six times; there were two deaths in the 30 cases, which represents a mortality of 7 per cent. But I must state that in two of the patients on whom I had not performed a gastro-enterostomy I had to do so within three weeks of the operation for closure of the perforation, owing to the appearance of well-marked

* A paper delivered to the Rochdale Division of the British Medical Association on October 16th, 1929

cumulative vomiting; both these two did well. The mortality of perforated gastric ulcer in the Manchester Infirmary statistics is nearly three times that of the perforated duodenal ulcer; the following factors are responsible, I believe, for this disparity in results: the gastric perforation is commonly much larger than the duodenal perforation, the escape of contents is therefore greater, and the spontaneous sealing up of the perforation by fibrinous adhesions is for the same reason not so often accomplished as it is in duodenal ulcer perforation; the escaping contents from gastric perforation are probably more highly infective; and, lastly, the closure of the perforation is commonly more difficult, and therefore more insecure. In operating on perforated gastric ulcer it is my practice, whenever the closure of the perforation is difficult and unreliable, to perform a high jejunostomy for feeding purposes; this step I strongly recommend in such circumstances. It is interesting to speculate on the risk of perforation which a given patient with ulcer runs; it is impossible to estimate this, and clearly the risk must be much reduced by proper treatment (medical or surgical) of the ulcer. The Manchester Infirmary figures of 400 non-perforated ulcers and 135 perforated ulcers per year represent the proportion of perforations to the total number of ulcer patients as 25 per cent., but the risk cannot be so high as that; possibly 10 per cent.—rather more for duodenal and less for gastric ulcer—may not be far out.

In regard to the treatment of the other acute complication, haemorrhage, there has been a good deal of discussion in recent years as to the advisability of immediate operation for the purpose of arresting the haemorrhage. In the case of a sudden and severe bleeding from an ulcer most surgeons are opposed to immediate operation for the arrest of the haemorrhage, because the majority of such patients recover under medical treatment. Still, in view of the fact that the mortality from ulcer haemorrhage treated by medical measures is not negligible—for it is probably in the neighbourhood of 10 per cent.—it would seem to me unwise to make the policy of non-surgical intervention an inflexible rule. In certain circumstances the advisability of immediate operation should still be carefully considered—for example, the case of the patient who is seen a few hours after the first severe attack of haemorrhage, whose condition is still quite good, and who in other respects is a healthy subject. If it is known, as the result of previous investigation, that the ulcer is duodenal, or, if gastric, is in a position easily accessible, then it is very doubtful if the risk of immediate operation at the hands of a practised surgeon is equal to the risk of non-operative treatment. It is mortifying in the extreme to witness, a day or two later, the sudden reduction of such a patient to a state of intense anaemia as the result of a recurrence of the haemorrhage; the feeling that the golden opportunity has been allowed to pass is irresistible.

There is less room for difference of opinion in the case of persistent or recurrent small haemorrhages, as may be met with occasionally in duodenal ulcer at or past middle life; in this type surgical treatment is strongly indicated.

In the treatment of ulcer patients suffering from severe haemorrhage I would particularly draw attention to the value of whole blood transfusion, as distinct from citrated or defibrinated transfusion; whole blood appears in such cases to have a special haemostatic effect in addition to the well-recognized restorative action common to all methods of transfusion.

The more insidious and chronic complications produced by healing of an old ulcer—pyloric stenosis by the duodenal and prepyloric ulcer, and the less frequent hour-glass contraction of the stomach by lesser curvature ulcers—are well recognized as necessitating surgical treatment for their complete relief, though no doubt much can be done by medical measures for early cases of pyloric stenosis in which the stenosis is due in part to spasm and inflammatory swelling. The striking benefit to be obtained by a well-executed gastro-enterostomy in a patient suffering from cicatricial pyloric stenosis is so well known that it is unnecessary to dwell on it. So, too, the operation of partial gastrectomy in cases of hour-glass contraction of the stomach gives results almost equally good, though with a rather greater risk. It is interesting to note here that one has met with several cases of pyloric stenosis in which the previous phase of ulceration has been accompanied by such mild and infrequent symptoms that the patient has not sought treatment, or only in a very casual way, till the onset of obstructive symptoms—notably cumulative vomiting—has been produced by contraction of the healing ulcer.

In a consideration of the chronic complications of ulcer an allusion must be made to the relationship of gastric carcinoma and chronic gastric ulcer. That carcinoma does occasionally develop in the edges of a chronic gastric ulcer is certain, but that it happens in any considerable proportion of ulcer cases I do not believe. Knowing what we do about the liability of carcinoma to follow chronic ulceration or long-continued irritation of the epithelial surfaces in other parts of the body, one would be disposed to accept the contention whole-heartedly in the case of the stomach were it not that clinical experience of gastric ulcer and of gastric carcinoma fails to support it. In this paper it is not possible to discuss the evidence, but it does appear to me that the risk of malignancy supervening on chronic gastric ulcer is so small that the contingency should weigh but lightly when we are called upon to decide between medical and surgical treatment. Of course, the position is quite different in that group of gastric cases in which, after full investigation, there remains a doubt whether the lesion is an ulcer or an early carcinoma; in this group operation is strongly indicated.

And now, what of the treatment of the uncomplicated chronic gastric and duodenal ulcer? If we accept the claims made by the physicians in the last few years, then surgery would appear to occupy a small and precarious position in the treatment of this the largest class. This swing of the pendulum towards medicine, particularly in the duodenal ulcer class, is overdue, and must be welcome to many abdominal surgeons because it will make for a higher standard of medical treatment and after-care than has hitherto been attained, and in this way to a more just discrimination in the selection of cases for surgical treatment. That surgery is still very necessary in particular cases, and will continue to be necessary, I do not doubt. One difficulty we have in deciding the relative merits of medical and surgical treatment arises from the fact that, while we have a good deal of statistical information about the late results of surgery, there is as yet not much information available about the late results of medical treatment. That the ulcer in its early stages, before it has attached itself to and eroded other viscera, will heal permanently under efficient medical treatment cannot be doubted—operation and post-mortem observations, as well as clinical experience, establish this. It is also certain that the longer the duration of the ulcer symptoms and the greater the number of relapses before the patient comes under efficient medical treatment, the more refractory will the ulcer prove to this treatment, and the greater its tendency to relapse under the strain of ordinary life. It must be emphasized that the healing of an old-standing ulcer is by no means tantamount to cure, though, of course, it is a substantial step in that direction. I have on three occasions resected the portion of the stomach wall bearing an ulcer which appeared to have healed to such an extent that the unpractised eye would have had difficulty in detecting the existence of an ulcer in the specimen. Yet in these patients their symptoms had persisted up to the time of the operation; in all the history extended over a period of not less than four years, and was marked by severe relapses, accompanied in two by attacks of severe haematemesis. In one a careful radiographic examination failed to disclose the presence of an ulcer, though it showed a persistent spasm of the greater curvature opposite the ulcer site.

There is one type of ulcer, infrequent but distinctive, in which surgical treatment is essential for the complete relief of the patient. The ulcer I have in mind is situated in the posterior wall of the stomach, though usually involving the lesser curvature as well, or in the posterior wall of the duodenum; in either case the ulcer is burrowing deeply into the pancreas. If the ulcer is in the anterior wall of the stomach, then it is attached to and eroding the liver; the ulcer crater, if gastric in position, may be as large as a five-shilling piece. A striking feature of such ulcers is

the persistent pain in the epigastrium and in the back, to the right or left of the lower dorsal spine according as the ulcer is duodenal or gastric. The pain, though constant, is made worse by nourishment, and may necessitate the use of opium, especially at night. Frequently there are repeated haemorrhages. The gaunt, haggard, and anaemic facies of the patient is a characteristic feature. In my experience many of these patients respond very poorly or not at all to the careful medical treatment of my medical colleagues, but a well-planned operation gives immediate and complete relief which, with reasonable after-care, is, I believe, lasting. But apart from such a severe type as this it is not possible to lay down hard-and-fast indications for surgical treatment in the uncomplicated ulcer. We have to consider not only the essentially medical factors—that is, the clinical and radiographic features and the responsiveness of the ulcer to medical treatment—but also the economic and social circumstances of the patient.

A really prolonged course of treatment, to be followed by regulated diet and habits, is an ideal not often realizable by patients of the hospital class, hence the appeal of surgery, with its prospect of a more rapid cure and a reduced risk of relapse under normal conditions of life to this particular class. Without doubt this is the chief reason for the large proportion of ulcer cases in the surgical wards of the Manchester Royal Infirmary. Another factor that enters into the question is the surgeon's faith in his own methods—a faith to be derived and proved from his experience, and not from his impressions.

The scope of this paper is not intended to include a consideration of surgical technique, but recently so much has been written and spoken about the value of gastro-enterostomy in the treatment of duodenal ulcer that a brief allusion may be made to this subject. Many surgeons, probably a considerable majority, regard gastro-jejunostomy as the best operation for duodenal ulcer. My own experience has led me to prefer pyloroplasty—either of the Finney or Horsley type, but when possible the former—combined with excision or cauterization of the ulcer. I believe this operation gives results as good as the best after gastro-jejunostomy, but without entailing the liability to such a grave, if infrequent, sequel as gastro-jejunal ulcer or to the less serious troubles met with after gastro-jejunostomy for duodenal ulcer. Since the foregoing remarks about gastro-jejunostomy for duodenal ulcer were written, the late results in 331 duodenal ulcer patients, on whom gastro-jejunostomy had been performed at the Manchester Royal Infirmary at least five years before the inquiry, have come to hand, and it is noteworthy that 15 per cent. of the patients were found to complain of "slight symptoms" and 13 per cent. of "very definite symptoms."

The inquiry into the late results of gastro-enterostomy which is being conducted at the present time by the British Medical Association throughout the whole country should afford some valuable information about the position of this operation in the treatment of duodenal ulcer, and it was in furtherance of this inquiry that the figures I have just quoted were obtained.

THE PROPHYLACTIC TREATMENT OF PATIENTS WHO HAVE HAD ALBUMINURIA IN A PREVIOUS PREGNANCY.*

BY

LOUIS C. RIVETT, M.Chir., F.R.C.S.,

CONSULTING OBSTETRIC SURGEON, EAST END MOTHERS' LYING-IN HOME; SURGEON TO IN-PATIENTS, QUEEN CHARLOTTE'S HOSPITAL.

I HAVE been stimulated to make this preliminary communication on the prophylactic treatment of cases which have had albuminuria in a previous pregnancy by papers by Young and Gibberd. These writers have shown that a large number of cases of albuminuria of pregnancy are followed by permanent renal damage. I must emphasize that this is only a preliminary communication, and the method of prophylactic treatment outlined is still in the experimental stage, but I hope that the details of the cases we have treated will stimulate others to impress on all patients who have albuminuria of pregnancy the necessity in any subsequent pregnancy of placing themselves under expert care at the very earliest moment.

At Queen Mary's Hospital for the East End, where this investigation is being carried out, we have always explained to every patient the urgent necessity of reporting immediately a period is missed, and the majority of patients becoming pregnant again after albuminuria or eclampsia have come under observation at six to ten weeks after the commencement of the last menstrual period. The investigation has been carried out in collaboration with Dr. A. A. Osman, physician to Queen Mary's Hospital for the East End, and Dr. H. G. Close, working for the Medical Research Council.

The theory on which this investigation is based is the result of an extensive examination carried out by Dr. Osman for the Medical Research Council on cases of scarlatinal nephritis, and the essential feature is maintaining the reaction of the urine throughout the whole of pregnancy at a minimum alkalinity of *p*H 7.7. In order to achieve this it is often necessary to give quite large doses of alkalis by the mouth. To guard against overdosage it is advisable to estimate the bicarbonate content of the blood plasma, and this is done by the method of Van Slyke, Stillman, and Cullen, described in the *Journal of Biological Chemistry* in 1919. This estimation must be repeated at intervals, especially if any change in the original dose is indicated. In normal non-pregnant women the average plasma bicarbonate is about 0.030 molar concentration. In 85 per cent. of pregnant women there is considerable reduction, an average being about 0.0247. This blood analysis is somewhat intricate, and cannot be carried out without proper laboratory facilities. The reaction of the urine can easily be ascertained in a very few minutes by colour comparisons with standard phosphate mixtures, using methyl red and brom-thymol blue as indicators. We have found that the dose which is usually both safe and effective is about 400 grains a day of equal parts of sodium bicarbonate and potassium citrate. This may have to be varied according to the reaction of the urine and the bicarbonate content of the plasma. In some cases we have had to give as much as 780 grains—over an ounce and a half a day—while in others the dose may be reduced to a drachm or two a day.

The patient is advised to diet. The protein intake is reduced by curtailing the amount of meat, milk, and eggs. Milk is allowed in tea, coffee, and milk puddings, but is not allowed as a beverage. Eggs are not allowed in quantity, but one egg may be taken every other day. Meat of all sorts, and particularly red or greasy meat, is to be taken sparingly, and only every other day. White fish (not salmon, mackerel, etc.) may be taken freely, and vegetables and fruit *ad lib.*

As regards general hygiene, special attention should be paid to the bowels, and a free action daily must be ensured. Fresh air and gentle exercise are of importance, and at the same time the patient must take plenty of rest and avoid all strenuous exertion.

I will now relate case details of fourteen patients, some of whom have been on a modified treatment.

CASE I.—*First pregnancy in 1925. Emergency, after delivery with post-partum eclampsia. Second pregnancy in 1927. Under observation from tenth week. Small doses of alkali only. No albumin. Live baby at term. Third pregnancy in 1929. Under observation from seventh week. Small doses of alkali only. Patient was found to have threadworms, for which she was treated. No albumin. A normal healthy-looking baby died during labour at term. There was no post-mortem examination.*

CASE II.—*First pregnancy in 1923. Admitted after delivery with post-partum eclampsia. Second pregnancy in 1925. Under observation from eleventh week. Small doses of alkali only. Albuminuria. Premature baby stillborn. Third pregnancy in 1928-29. Under observation from twelfth week. Full alkali treatment (400 grains). No albumin; no oedema. Macerated foetus.*

CASE III.—*First pregnancy in 1924. Eclampsia. Second pregnancy in 1927-28. Under observation from sixth week. Full alkali treatment (400 grains). No albumin. Live baby at term.*

CASE IV.—*First pregnancy normal. In the second pregnancy albuminuria and oedema were present. In the third the patient was on full alkali treatment from the twelfth week. No albumin; no oedema. Live baby born at term.*

CASE V.—*In the first pregnancy the patient suffered from eclampsia. In the second pregnancy she was under observation*

* Read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Manchester, 1929.

and alkali treatment from the tenth week. There was a trace of albumin at the twenty-second week. Alkalis were increased up to 720 grains a day. Albumin disappeared. Live baby born at term.

CASE VI.—First pregnancy in 1927. Albuminuria. Premature twins born alive. Second pregnancy in 1928-29. Under full alkali treatment from the sixteenth week. No albumin; no oedema. Live baby at term.

CASE VII.—Patient had nephritis at the age of 10. Albuminuria and oedema were present before pregnancy. She was under observation from the fourteenth week. She was given 400 grains a day, later reduced to 150 grains a day. No albumin; no oedema. Live baby at term.

CASE VIII.—In the first pregnancy eclampsia was present. Baby stillborn. During the second pregnancy the patient was on alkali. No albumin until two days before delivery, when a trace was found. Live baby at term.

CASE IX.—First pregnancy: albuminuria present. Premature baby weighing 3 lb. 2 oz. born alive; lived two days. In the second pregnancy patient was under observation from the twelfth week. Small amounts of alkali only. No albumin. Live baby at term (6 lb.).

CASE X.—First pregnancy in 1925-26. Admitted with gross albuminuria. Live baby. Second pregnancy in 1927. Under observation from the eighth week. Small amounts of alkali only. No albumin Live baby at term.

CASE XI.—First pregnancy in 1925-26. Admitted with gross albuminuria. Premature baby weighing 3 lb. 8 oz.; lived four days. Second pregnancy in 1927. Under observation from the tenth week. Small amounts of alkali only. No albumin. Live baby at term.

CASE XII.—First pregnancy in 1921. Admitted with eclampsia. Baby stillborn. Second pregnancy in 1925. Under observation from the fourteenth week. Small amounts of alkali only. No albumin. Live baby at term.

CASE XIII.—First pregnancy ended by miscarriage about the twenty-fifth week. Albuminuria; blindness. The second pregnancy was a repetition of the first. In the third pregnancy patient was under observation from the twelfth week. Full alkali treatment—150 grains, increased to 350 grains. No albumin. Live baby at term.

CASE XIV.—First pregnancy normal. In the second pregnancy albuminuria and oedema were present during the last two months. Premature baby born alive. In the third pregnancy the patient was under observation from the twenty-sixth week. She was given 400 grains, increased to 500 grains daily. No albumin or oedema. Live baby at term.

GAS-OXYGEN IN MIDWIFERY.*

BY

H. EDMUND G. BOYLE, O.B.E., M.R.C.S., L.R.C.P.,

SENIOR ANAESTHETIST TO ST. BARTHOLOMEW'S HOSPITAL.

For many years past I have thought that the statement "Pregnant women stand chloroform well" was a mistake—merely copied from one book to another. I felt that it was obviously wrong to give a woman at the time of the birth of her child an anaesthetic so potent, so toxic, so dangerous as chloroform; but it was the accepted idea which had been handed down to us from the late Sir James Y. Simpson, and so it was a sort of gospel that is believed in even now, although there have been a very large number of fatalities—fatalities which will continue so long as this method is employed.

In this communication I propose to put before you a newer and, I think, a better idea—it is the administration of gas and oxygen for childbirth. This method has been familiar to me for some time from the literature of anaesthetics in Canada and the United States of America, but it was not until 1921 when, as the representative of the Anaesthetics Section of the Royal Society of Medicine, I went to Canada and the United States, that I first had personal and practical knowledge of it. I should like here and now to say that my introduction to this most valuable method was due almost wholly to Dr. Wesley Bourne of Montreal. The method has both advantages and disadvantages, and I propose to deal with them in that order.

Advantages.

1. The patient is given gas and oxygen with every pain—and after a few minutes she learns to ask for the mask as a pain is starting; she soon finds out that a few breaths of gas and oxygen will greatly diminish her pain, and when she realizes that she can go on having it, and that it will not slow her labour or hurt either herself or her baby, she is delighted.

2. The gas and oxygen, being non-toxic, can be given for a very long time without any harm to the mother or child—provided always that cyanosis is never allowed to be present. (My longest case so far has been eleven and a half hours.)

3. As this anaesthetic is non-toxic, it follows that the mother and the child have less to eliminate afterwards than if they are given chloroform. In connexion with this I well remember a case when the mother and child were both yellow for many days after a long chloroform administration, and yet with her next baby the mother refused to have the newer and, in my opinion, better anaesthetic.

4. The anaesthetist can greatly reduce the obstetrician's work, for if he knows enough of midwifery he need not send for the obstetrician until about an hour before the child is born. This is a point that I commend to the notice of the obstetricians.

5. The patient soon gets to an analgesic state, and between the pains is quite conscious, and indeed in some cases inclined to be talkative.

6. Finally, towards the end of the confinement, when the head is on the perineum, a little ether can be turned on, and the patient rendered completely unconscious, then, as the head is born, the ether is shut off, likewise the gas, and a mixture of CO_2+O (1 to 6) is given; this increases the respirations of the mother both in rate and amplitude, and as a result the baby becomes rosy pink and begins to "give tongue."

7. After the child is completely delivered, it is quite easy to deepen up the anaesthesia for the delivery of the placenta, and in my experience women who have had this form of analgesia *plus* anaesthesia recover consciousness very soon; and long before one can pack up one's things and leave they are quite conscious and full of gratitude, especially those who have had chloroform for their previous confinements.

Disadvantages.

1. A special anaesthetist has to be present, and one who knows the method. It is not a method for one man to do both anaesthetic and confinement.

2. He must have an apparatus suitable for the occasion. The obstetric sets can be hired at a small charge for the use of the machine, and when returned to the makers they see how much of the gases have been used and charge for them as well.

3. The anaesthetic is naturally more costly than when chloroform is given.

The impression left on my mind by the cases that I have attended is that the pains are by no means slowed; indeed, I think that in some cases, where plenty of oxygen has been used, the pains seemed to be increased both in frequency and in strength. This, however, is merely my impression. I cannot prove it. There is one point, however, that I am sure of, and it is that the patients are far less exhausted, even after a long labour, with gas and oxygen than they are after chloroform; moreover, they recover much more quickly.

It is essential to remember that throughout the whole administration the patient must be kept pink. Cyanosis should never be present, since if allowed for any time the life of the child will be endangered.

I prefer to start the anaesthetic at the commencement of the second stage of labour, but if the patient is a nervous primipara then it can be started before. My usual custom when I begin is to have the gas-bag nearly full of gas and oxygen in the proportion of about 4 to 1, and to tell the patient to take three or four big breaths, and then to hold her breath. She will then feel a sort of pleasant feeling of well-being permeating the whole body, and the pain will be dulled. It is only necessary to give the gas and oxygen with each pain; it should not be given continuously. Later on, when the expulsive pains begin, the patient is told to take four or five big breaths and then strain down. They know a pain is on, but, as they are analgesic, they will obey instructions and strain down.

Care must be taken to see that when the head is on the perineum the expulsive pains are under proper control. By this I mean that the patient must be quiet, and to do this, as I said before, a little ether is mixed with the gas.

*Read in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

and oxygen, the pains are controlled, and tearing of the perineum is avoided.

I am quite convinced in my own mind that anyone who has seen a labour conducted under gas and oxygen analgesia, with a brief period of anaesthesia for the actual birth, will never willingly give anything else. The method is comparatively new in this country, and it may take years to develop and spread, but I feel sure that by its adoption a certain number of lives—both of mothers and children—would be saved. This is a point of paramount importance, and one that I am certain will appeal greatly to everyone who has the welfare of women in childbirth at heart.

THE DRUG TREATMENT OF SPASMODIC RHINORRHOEA.*

BY

W. M. MOLLISON, M.CHIR., F.R.C.S.,

SURGEON TO THE EAR AND THROAT DEPARTMENT, GUY'S HOSPITAL.

THE name "spasmodic rhinorrhoea" is symptomatic and serves well; vasomotor rhinitis, spasmodic rhinitis, paroxysmal rhinitis, and intermittent neurotic catarrh are alternatives. Perhaps I should now use the more up-to-date phrase "nasal manifestation of allergy." The subject of "allergy" is wide, and embraces many conditions which up to now have been regarded as entities—asthma, hay fever, rhinorrhoea, urticaria, intestinal disturbances, angioneurotic oedema. It is now recognized that all these diseases are manifestations of reaction of body cells to stimuli, many of which are not known. In our specialty one of the stimuli is known—pollen in the production of hay fever. It is thus seen that the subject chosen for these notes is only a corner of a wide field.

No doubt eventually it will be possible to treat each case appropriately; in the meantime, empiricism plays an important part. In these cases of mine that empiricism is everything, as no investigation was made to discover the exciting cause of the symptoms. Briefly, the symptoms of spasmodic rhinorrhoea are a watery discharge from the nose, accompanied by or preceded by sneezing. The symptoms vary a good deal in degree.

Many people who look on themselves as normal sneeze several times on rising in the morning; many more sneeze on looking at the sun. One man, a medical student, had a bad bout of rhinorrhoea and sneezing only at week ends. At the other end of the scale there are patients who suffer from rhinorrhoea or sneezing all day; so profuse is the rhinorrhoea that it wakes them, and before they have time to reach for a handkerchief their nightgowns are soaked. In one case the patient sneezed thirty to fifty times before breakfast, another a hundred times. Occasionally the sneezing is so severe that the patients are completely exhausted; on one occasion such a patient had to be placed in a nursing home and given morphine to check the sneezing. Between these extremes there are many grades. Patients often feel exhausted and children complain of *tiredness on playing games.*

I do not pretend to know when the suggestion of thyroid administration was first mooted, but it was suggested to me by the case that I now quote. Some years ago I was consulted by a lady for nasal symptoms which had developed since she became pregnant; these symptoms were nasal obstruction, rhinorrhoea, and sneezing. Thinking that some error of *internal secretion might be the* cause, I gave thyroid extract, with good results. After pregnancy was over all symptoms disappeared. This lady came to see me again during the next pregnancy with recurrence of symptoms; the same treatment cured her. This, of course, was cheering to me as well as to her, and in my mind established some internal secretion error as an underlying factor in cases of spasmodic rhinorrhoea, and a tendency developed to treat all my cases similarly, regardless of age or sex. The following case also *suggested that some metabolic error might be present.* A woman of 55 attended the out-patient department at Guy's Hospital on account of rhinorrhoea so profuse that her life was rendered miserable; it woke her *at night, and her nightgown* was soaked before she could reach her handkerchief. After one week's treatment with thyroid she was cured. Then, in 1919 or 1920, Dr. Mayo read a paper at the Royal Society of Medicine on the importance of calcium to the human economy. The impression left on my mind was that all human ills were the result of lack or perhaps excess of calcium. Calcium was therefore added to the thyroid.

TREATMENT.

The details of treatment have varied slightly from time to time: the earlier cases received thyroid extract; later calcium lactate and parathyroid were given; other forms of calcium employed were kalzana, tricalcine, and, in a few cases, collosol calcium. The dose is 15 grains of the calcium and 1/10 grain of parathyroid extract; of thyroid extract 1/2 grain twice a day, though this may have to be reduced; of collosol calcium 1 drachm twice a day. In two cases quinine was given when hyperthyroidism was suspected.

Before starting treatment one tries to exclude obvious mechanical abnormalities in the nose—sinus infections, polypi, adenoids.

RESULTS.

As indicated above, the results of this treatment are sometimes dramatic; but many cases that appear typical fail to respond at all. Perhaps one or two cases are worth quoting.

Case 1.—A boy of 12, a doctor's son, was subject to asthma; he had a very sensitive nose, a mere touch being enough to make him sneeze. The mucous membrane of the nose was pale. He was given 15 grains of calcium lactate and 1/2 grain of thyroid extract twice a day. His father wrote that the boy had been better in health that term than ever before; the "colds" disappeared, also all asthma. In error he had been having 1/2 grain of thyroid gland, instead of extract, so that the result of treatment must almost surely have been due to the calcium. It was found that if the calcium was stopped the "colds" returned.

Case 2.—A boy of 16 in September, 1927, complained of nasal obstruction and "colds"; he had some shortness of breath, which was considered to be asthma by a competent observer. He sneezed a great deal and had much rhinorrhoea. He was given 15 grains of tricalcine and 1/10 grain of parathyroid extract twice a day. Two months later all symptoms had disappeared, and he had lost his shortness of breath. His doctor considered all his troubles to be due to infected tonsils, and was, I fear, annoyed with me that I would not remove them. The boy has remained perfectly well.

Case 3.—A lady of 47, seen in October, 1927, complained of "nasal catarrh" of a few years' standing. She had intense nasal irritation, watery discharge, and violent sneezing, chiefly at night, which wakened her at 3 to 5 a.m. She was given 15 grains of tricalcine and 1/10 grain of parathyroid extract twice a day. In November—one month later—she wrote saying that she was almost well.

Case 4.—A man of 45, a schoolmaster, seen in February, 1926. He had had hay fever for twenty-three years, and then began getting symptoms all the year round, and this had culminated in a very severe attack of rhinorrhoea and sneezing, which had exhausted him. He had tried many remedies, and confessed that he came with little faith or hope. After taking calcium lactate and parathyroid for fourteen days he wrote that he was cured—"the stuffy breathless oppression has gone, and I have had practically nothing since."

Case 5.—A boy of 11 was seen in 1926; he was never free from a cold; he had had various operations on this account. At 5 years of age he had had adenoids removed; at 9 tonsils removed; at 9½ tonsils enucleated and some operation on the nose; he had also had appendicitis. In spite of all his adventures no improvement had resulted; the nose was always blocked, and he had headaches and a lot of sneezing in the mornings. Examination showed that the anterior end of the right inferior turbinal had been removed, also, of course, the tonsils and adenoids. Calcium lactate and parathyroid were given; the result was good, he ceased sneezing in the morning, scarcely had to use a handkerchief, and felt very much better. One may wonder in this case whether the appendicitis was not really another manifestation of allergy.

Case 6.—The following case shows the occasional rapid result of treatment. A nurse, aged 42, had such profuse rhinorrhoea that she had to use towels in place of handkerchiefs; it also woke her at about 3 a.m.; she had much sneezing. After three or four days of calcium and parathyroid she wrote to say she was cured.

Details of all the cases would be of no interest, but here are the results in 40 consecutive cases which were followed up as far as possible:

Cured	15 = 37%	65%
Better	11 = 27%	
No better	5	
Not traced	9	

It is not suggested for a moment that 65 per cent. of cases of rhinorrhoea will be cured by giving calcium and parathyroid; but the results in even this small number are at least encouraging.

* A paper read in the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Manchester, 1929.

PNEUMOPYOPERICARDIUM: THE RADIOLOGICAL DIAGNOSIS.

BY

JAMES F. BRAILSFORD, M.D.B'HAM., M.R.C.S.,

THE QUEEN'S HOSPITAL, BIRMINGHAM.

(*With Special Plate.*)

THE conditions of pneumohydropericardium and pneumopyopericardium are rarely diagnosed. They may exist, yet their presence may be unsuspected owing to their insidious development during the progress of a grave lesion, or to the physical signs and symptoms of the primary lesion masking those of these conditions.

Pneumopyopericardium may arise from any lesion which leads to perforation of the pericardium *from within* or without; thus it may be associated with:

1. Rupture of the pericardium by a foreign body in the oesophagus or stomach or by a puncture wound.
2. Paracentesis.
3. Direct violence—with or without a definite fracture of a rib or the sternum.
4. *Artificial pneumothorax.*
5. The breaking down of a tuberculous lesion which is in close proximity to the pericardium.
6. The rupture of *inflammatory lesions near the* pericardium —abscess (lung, liver, subdiaphragmatic), *empyema*, etc.
7. Carcinomatous ulceration of oesophagus, bronchi, or stomach.

The *perforation* of the pericardium by foreign bodies is rare in man, but *in cattle it is fairly* common. One has seen a number of cases at the public abattoir due to the swallowing of *long strips* of sharp metal or wire, which have torn through the viscera into the pericardium and infected it with *organisms from* the alimentary canal. The *animals* have become obviously so seriously ill that they have been sent to the abattoir for the purpose of "saving their lives"—*or, in other* words, to get early slaughter with the idea of *being able to sell* the meat. Infection of the pericardium by organisms of the *B. welchii* group readily leads to the *development of pneumopyopericardium.* Imperatori[1] *records a case of* pericardial oesophageal fistula following impaction of a foreign body in the oesophagus.

During the needling of the thoracic cavity the pericardium may be ruptured and infected, and the condition so produced. Rigler[4] records such a case. Ljungdahl[5] has described a case of pneumopericardium occurring in a lad, eighteen years of age, who, whilst running, suddenly experienced a severe pain in the chest, with breathlessness and a feeling of obstruction in the bronchi, followed by a loss of strength. Peterson described a case in which he said that the alveoli were ruptured and air collected between the pericardial pleura and the pericardium. Saupe[3] has emphasized the possibility of confusing this with pneumopericardium. That pneumopericardium can arise as the result of an artificial pneumothorax is shown by the history of the case recorded by Saupe.

Wenckebach[12] has described a case of pericarditis with effusion associated with phthisis treated by repeated withdrawal of the effusion and replacement by air. On one occasion as much as 1,400 c.cm. of fluid was withdrawn and 600 c.cm. of air introduced. It was found that the introduction of air considerably reduced the rate of exudate production, and altered its character from haemorrhagic to clear serous fluid, and consequently greatly improved the condition of the patient. His radiograph of the artificial pneumopericardium shows that the *pericardium* is very considerably dilated to the left, and to a much less extent on the right. On the left it reached to the level of the *fourth* space posteriorly and to the first costochondral junction anteriorly, and on the right from the diaphragm to the sixth *rib* posteriorly and the second space anteriorly. It has been shown at post-mortem examination that pneumopyopericardium has arisen as a result of rupture of the *pericardium secondary to* tuberculous cavitation, empyema, abscess or gangrene of the lung, or carcinomatous ulceration of the oesophagus, bronchi, or stomach.

DIAGNOSIS.

The diagnosis of pneumopericardium can only be definitely established by an *x*-ray examination. In the case to be described, the reason for the *x*-ray examination was the gravity of the dyspnoea, which appeared to have developed *rapidly. The physical signs for several years suggested the* diagnosis of phthisis. No additional physical *signs* were detected to account for this marked dyspnoea, and its onset had been insidious. The suspicion of pericarditis had not been aroused by any of the physical signs. Normally the *pericardium* invests the heart *so closely* that it cannot be *seen on the radiograph (except perhaps at the left cardiophrenic* angle), even if pericarditis exists, unless this has been present over a long period and calcification of the pericardium has occurred. Even when a pericardial effusion is present the radiograph may not determine its presence, though Schultze,[9] Schwaer,[10] Amelung,[1] and others have demonstrated radiographs which show a double *contour* to the heart shadow—the inner shadow being interpreted as the heart shadow and the outer shadow that of the fluid in the pericardium. It may be possible to demonstrate this in a few selected cases where the respective densities of the heart and fluid permit, but it is by *no means a common finding. Definite cases of pericarditis* with effusion occur in which no such radiographic shadows can be obtained. Moreover, such appearances may be shown on antero-posterior radiographs where no pericarditis is present; such lesions as a pleuritis mediastinalis or dilated oesophagus or paravertebral abscess or aneurysm of the abdominal aorta[3] may give such a picture.

It is essential in the radiography of the heart that the best technique be adopted, and the chief factor is undoubtedly shortness of exposure. As in gall-bladder radiography, important features may be entirely missed if the duration of the exposure is not sufficiently short to give a sharp outline. I have drawn a resemblance between such *radiography and photography of crowded thoroughfares.*[2] If the exposure of the latter is long enough only a clear photograph of the buildings and fixed objects will be obtained, whereas with a reduction in the time of the exposure the moving objects begin to be portrayed until with very short exposures even the detail of the fast moving cars will be shown.

Similarly with radiography of the thorax. If the exposure is so long that *movement of the heart can occur*—not only on account of pulsation but also of breathing—it is possible to produce a radiograph which shows the detail of the spine but little or no heart shadow. As this radiograph appears to have been "accurately" exposed it may be regarded as satisfactory. Indeed, I have seen such a radiograph exhibited and the suggestion seriously put forward that the absence of the heart shadow might be due to diminished density of the heart in phthisis.

With the very short exposures from a distance which are possible when using the big modern transformer sets and time switches, it is possible to obtain radiographs on which the outline of the heart is as sharp as if it had been drawn. With such exposures it only needs slight difference in the density of different structures to get an outline of their form, and it is with such radiographs that the greatest help in diagnosis can be obtained.

Description of Case.

A man, aged 40, had complained of a cough for some years. His sputum had been examined on several occasions for the tubercle bacillus with negative results. After an operation for appendicitis a fistula had developed *in the right iliac fossa* and persisted for nearly two years. This healed, but broke down again after four years, and during the past two years has widened considerably, and is *now most* offensive. Five months ago he developed dyspnoea. Dr. Benjamin Dale of Birmingham—to whom I am indebted for the history, clinical details, and permission to record the case—had attended him for several years. He re-examined the thorax with the development of the dyspnoea, but could find no new physical signs, and on this account requested an *x*-ray examination. On screening the chest, the lung fields, particularly in the upper half, showed much of the mottling which suggests chronic fibrotic changes. It had the appearance seen in cases of chronic phthisis, though no definite cavity formation could be detected. *Marked* emphysema of the lower lobes was suggested by the *lighting up* of these areas and the depression of the diaphragm and its small excursion.

A large localized collection of fluid with gas above was seen in the middle of the thorax, and when the patient was rotated it became obvious that the fluid and gas were contained in the

pericardial sac. The surface of the fluid could be seen to move with each pulsation, and when the patient was rotated lying down the gas bubble could always be seen lying above the fluid which flowed into the dependent parts. A further *x*-ray examination of the patient after he had been resting for one month showed no change in the appearance of the pericardium. About the same quantity of fluid and gas appeared to be present. His dyspnœa was perhaps a little less marked, and he was able to walk about without much distress.

After a further two months' rest another *x*-ray examination was made, and to our astonishment the whole appearance had changed. There is now no evidence of gas or fluid in the pericardium, and the heart shadow appears to be of normal shape and dimensions. His dyspnœa has practically disappeared and, excepting for his fistula, he feels much better. He stated that he had "vomited" a large quantity of foul-smelling matter since the previous examination, but it is impossible to say if this had any relation to the disappearance of the fluid from the pericardium. It would be remarkable to get such a complete evacuation and apparent healing and improvement in the patient's general condition if the fluid in the pericardium had been fetid pus containing gas-producing organisms, and I am inclined to the opinion that it was rather of the nature of a pericardial effusion following rupture of the pericardium and pleura, with entrance of air which was later absorbed. The appearance of the lung fields suggests that the underlying cause is tubercle, but no tubercle bacilli have been found in the sputum on any occasion.

Description of Radiographs.

The radiographs are instructive in showing the form which the *pericardium* may assume when dilated by a large collection of gas and fluid. It is generally taught that in pericarditis with effusion the area of precardial dullness becomes pear-shaped—the stalk of the pear reaching up to the level of the left sterno-clavicular articulation. It will be seen from the postero-anterior radiograph, Fig. 1 (and Fig. 1A, which is a tracing of Fig. 1), that the widest part of the pericardial sac in this case is at the level of the fluid surface, which is three interspaces above the level of the diaphragm, the base of the pericardium being narrower. The general shape of the pericardial sac is ovoid, excepting for the notch due to its attachment to the aorta and pulmonary artery.

FIG. 1A.—Tracing of outline of pericardium and fluid level from antero-posterior radiograph (Fig. 1).

Another noticeable feature is that the pericardium is more dilated to the left than to the right. This feature I also observed in the radiograph illustrating the case of artificial pneumopericardium by Wenckebach. The dilatation in my case is also seen to be more above than below. Curschmann recommends paracentesis in or lateral to the left mammary line in the fifth or sixth left interspace, in view of the fact that the fluid tends to collect on either side or below the heart rather than in front of it. These radiographs show that the features described are not necessarily present, and little success would have attended efforts to drain the pericardium if these recommendations had been adopted.

No dullness to the right of the sternum was detected, and this is to be explained by the shape of the pericardium and the emphysema of the base of the right lung. The lateral radiograph (Fig. 2) and the tracing from it (Fig. 2A) show the outline of the pericardium. This I thought was due to some thickening and calcification of the pericardium, and it suggested that the lesion had been present for a considerable time, but from the last examination I believe it to be due solely to it being the limiting membrane of the large gas-containing cavity. Its outline resembles that shown in the drawing of the posterior wall of the pericardial sac (Fig. 616 in *Gray's Anatomy*).

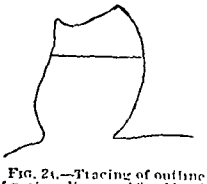

FIG. 2A.—Tracing of outline of pericardium and fluid level from lateral radiograph.

The radiographs also illustrate the importance of taking radiographs in several planes and rotating the patient during screening. It would be impossible from the antero-posterior radiograph to state definitely that the fluid and gas were in the pericardium.

Differential Diagnosis.

Similar appearances shown on the postero-anterior radiograph I have seen in a case of empyema localized in the mediastinal area which had been partly drained by needling; an echinococcal cyst which had ruptured and partly drained; a mediastinal tumour the middle of which had disintegrated, liquefied, and partly drained; and a large œsophagus with cardiospasm.

Other conditions, such as paravertebral abscess, aneurysm of the heart and descending aorta, and mediastinal tumour, would have to be considered if no gas collection was present. By rotating the patient during screening or by taking radiographs in several planes these conditions could be excluded.

A CASE OF PANCREATIC CALCULI.

BY

STANLEY N. SENNETT, M.B., B.S.LOND., M.D.BERL.,

CAPETOWN, SOUTH AFRICA.

(*With Special Plate.*)

IT is extremely rare for pancreatic calculi to be diagnosed during life, so that it is always of interest when such a diagnosis can be made with reasonable certainty.

The patient, an Indian, aged 37, was sent to me by Dr. G. Narunsky of Claremont, Cape, on February 19th, 1929. For the previous four to five months he had complained of pain in the epigastrium, which radiated to both sides of the abdomen. The pain seemed to come on five to ten minutes after food. For the past six weeks the pain was more severe, practically continuous, and was getting worse, so that for the last two weeks he had eaten very little. He had no attacks of colic, but only the dull continuous pain.

He had no appetite, no desire for food, had not vomited, and was not jaundiced. His tongue was furred and his breath very foul. The teeth were bad. His bowels were constipated, but latterly he had had a few loose, very small motions.

He had marked tenderness just above the umbilicus. The liver and spleen were not palpable. There was no glycosuria.

One of the stools was examined. It was very small in amount, contained little faeces, much mucus, and certainly was not a pancreatic "fat stool."

An Ewald-Boas test meal showed 50 per cent. free HCl and 66 per cent. total acidity. A barium meal *x*-ray examination was then made, and the four photographs reproduced in the special plate were among those taken (see Films A–D).

Film A (taken in the prone position) shows shadows in the loop of the duodenum and to the left of the first lumbar vertebra.

Film B (taken six and a half hours after the ingestion of the barium meal) shows the bulk of the meal in the ileum. A wire was placed on the abdomen to indicate the position of the abdominal tenderness. The shadows show quite plainly on the right of the body of the second lumbar vertebra, and across the body and to the left of the first lumbar vertebra.

Film C (taken twenty-six hours after barium meal) shows the ascending and transverse colon well filled and the shadows above the colon.

Film D was taken four days later, after the patient had had an enema and an aperient to clear the alimentary canal. The shadows show very clearly.

FIG. 1.—Postero-anterior radiograph of pneumopyopericardium. Note that the dilatation is mostly to the left side and more dilated above than below. Marked mottling of the lung fields, particularly the upper halves, the bases show emphysema.

FIG. 2.—Lateral radiograph of the thorax, showing pneumo- ium and its attach- also emphysema of the dorsal spine.

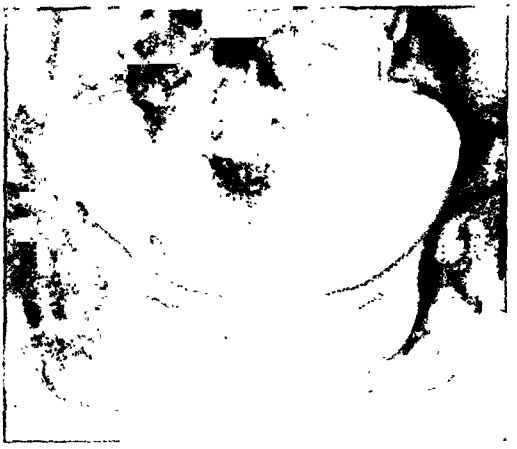
I. H. LLOYD-WILLIAMS: BONY PLAQUES DEVELOPING IN THE SKIN.

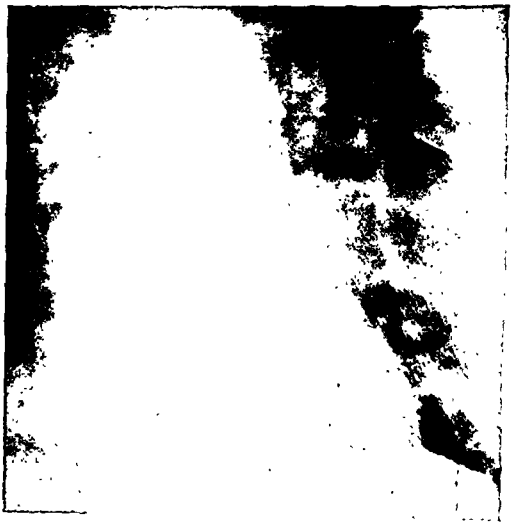
X-ray photograph of the case reported. Note the normal appearance of the bone and the superficial position of the plaques.

J. CLAY: BIMANUAL METHOD OF LOCATING A STONE IN THE URETER.



X-ray photograph showing stone in lower end of right ureter.

B. T. HALLIWELL: FRACTURE OF RIBS CAUSED BY COUGHING.



After an examination of the photographs a diagnosis of pancreatic calculi was made. I lost trace of the patient after that, but have since heard from Dr. Narunsky that, after having consulted several other doctors, the patient returned to him on May 22nd. He was then severely jaundiced and very emaciated, and died the same day. Unfortunately no consent could be obtained for a post-mortem examination.

Comment.

Certain points of interest emerge from a consideration of this case.

1. The pain was not typical of any particular gastric condition. It seemed to come on soon after food, but was not relieved by anything. Later, the pain was practically continuous.
2. The patient had no attacks of colic.
3. There was no glycosuria.
4. There were no fatty stools.
5. Jaundice was late, and was probably due to a pancreatic stone blocking the common bile duct.
6. The very probable diagnosis of pancreatic calculi from the *x*-ray examination, as the head, body, and tail of the pancreas are so definitely outlined by the shadows. Also the site of the abdominal tenderness coincides with the shadows seen.

ON A CASE OF BONY PLAQUES DEVELOPING IN THE SKIN.

BY

I. H. LLOYD-WILLIAMS, *M.C.*, M.B., B.S.,

HONORARY MEDICAL OFFICER, HAYWARDS HEATH HOSPITAL.

(With Special Plate.)

THE occurrence of calcification in tissues is well recognized. The presence of calcified deposits in the skin either as milia or in scars is described by Malcolm Morris and others. The existence of actual bony plaques in a cutaneous scar seems to me of sufficient rarity to be worth recording.

The patient is an elderly woman who, in 1924, got her right sleeve caught in the flame of a spirit lamp. The burn was a severe one, extending to the outer side from about two inches below the elbow to about six inches above, and in one part, just above the elbow, almost encircling the arm. Healing took about seven months, and skin grafting was resorted to. There was no trouble until about five years ago, when a plaque was extruded through the skin by a process of slow ulceration, taking about eight months for the ulcer to heal.

About a year ago last April "a little spot" started on the outer side of the arm, just above the elbow, which gradually grew larger. A calcareous plaque was observed in the process of extrusion. There was very little inflammatory reaction in spite of the presence of a little pus on the dressings. Solution of the plaque by lactic acid dressing to hasten the removal was tried without avail. The plaque was finally extruded and the residual ulcer healed in about three weeks. The plaque was sent to the Clinical Research Association, and they reported as follows:

"This specimen is found to be a piece of exceedingly hard, calcareous bone in which an excess of calcium salts has been deposited; it is also covered on one side by a hard deposit of calcium and magnesium phosphates. We regret the exceptionally long time taken in the analysis, but the specimen was so exceptionally hard that special means of softening and decalcifying had to be adopted."

The specimen was about one inch long by about half an inch wide and perhaps a sixteenth of an inch thick.

At the time of writing another plaque is commencing to come away and several others can be felt lying in the skin and movable over the underlying tissues. The *x*-ray photograph shows the calcareous deposits in the skin. I had this taken with a view to determining the state of the underlying bone; this is obviously healthy.

The chief interest in the case lies in the fact of actual bone seems tissue developing in an unusual position. So far as the history of the original injury and the present *x*-ray findings are concerned, the possibility of transference of osteoblasts from the humerus to the skin seems very unlikely. The most probable explanation is the conversion of connective tissue cells, either mature or in the early stage thereof in granulation tissue, into osteoblasts. This would bring the lesion into line with the ossification that occurs in callus and myositis ossificans.

I am indebted to Miss Ivatt, radiographer, Haywards Heath Hospital, for the radiograph, and to Dr. H. T. Cubbon, radiologist, for the following report:

"Lying in the soft tissues, posterior to the lower two-thirds of the humerus, there is a collection of opacities, which appear to be in the nature of plaques of bony tissue. Surrounding the plaque with a cavity in it, there is a collection of small granular opacities. The shaft of the humerus appears to be perfectly healthy, and although the bony opacities are very like sequestra, their origin could not be found. The appearances do not conform with a typical myositis ossificans."

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

LARGE LUNG ABSCESS WITH GANGRENE.

(With Special Plate.)

THE following case is thought to be of sufficient interest to be worth reporting.

A man, aged 63, was sent to the out-patient department of King's College Hospital by Dr. J. Shaw about June 1st, for haemoptysis of three weeks' duration.

History.—He had always been healthy and had never suffered from cough. In the beginning of May of this year he noticed a local anaesthetic about May 7th; the tooth was removed under a had taste in the mouth, generalized pain, and slight malaise; this was put down to a septic tooth, which became blood-stained, and later seemed to be pure blood, about an ounce at a time. At the end of May there was severe paroxysmal cough, often lasting an hour at a time, with pain in the right upper chest.

Physical Examination.—When seen, in the beginning of June, he was of the plethoric type, with a thick neck and slight cyanosis of the face and ears. The breath was very offensive; teeth extremely septic; no finger clubbing. Temperature 101°, respirations 20, pulse rate 84. In the right lung there was impaired movement and percussion note above the third rib; air entry was feeble, and there were numerous fine non-consonating crepitaticus; vocal resonance was increased. The heart was slightly enlarged to the left, without displacement, and there were no signs of aneurysm. Blood pressure 150/96. The liver was about three fingerbreadths down. On screening with the *x* rays a large opacity, the size of a grape-fruit, was seen in the right upper chest, with a fluid level, the amount of fluid did not decrease when the patient put the head low and coughed. (See radiogram in special plate.)

The diagnosis lay between lung abscess and interlobar empyema, causing acute congestion of the lung.

The patient was admitted to hospital early in June. The temperature was remittent between 99° and 102°, respirations 30, and pulse rate about 90. The sputum varied between 3 and 8 ounces daily; it was fetid, and consisted of brownish or bright red blood with pus. Microscopically it contained no broken-down lung tissue, but was teeming with bacteria of different types.

The physical signs altered very little, except that the air entry at the right upper lobe was very slight, on two occasions amphoric breathing was heard over the dull area, there was no whispering pectoriloquy or coin sound.

The diagnosis of pulmonary abscess with gangrene was made, but we were unable to account for the fact that the cavity did not empty materially on adopting a suitable posture; the large amount of fresh blood was also unusual. It was deemed inadvisable to try to tap the abscess by means of a trocar and cannula for fear of causing empyema.

The patient gradually became more toxic, and died suddenly after a fit of coughing on June 11th, after ten days in hospital.

Post-mortem Examination.—The teeth were very septic; oedema of the tissues of the right upper chest, neck, and mediastinum; serous fluid (35 ounces) in the right pleural cavity; the trachea was full of blood; old dense adhesions at the right apex and recent fibrinous adhesions over the right upper lobe in the axilla. The right upper lobe was converted into a huge gangrenous cavity with a mere shell of lung remaining; this was filled with blood-clot (at least 10 ounces) and broken-down lung tissue. The bronchus to the right upper lobe was occluded by gangrene and swelling, and was sticking into the cavity in such a way that it bent over at an angle; it would thus act as a valve, allowing air to enter but preventing the free expulsion of pus and blood (see photograph, Fig. 3). No foreign body was found.

There was acute congestion and early pneumonia in the lower lobes of both lungs. There was early pericarditis on the right side, with cloudy swellings and congestion of the various organs.

There seems little doubt that the origin of the condition was the inhalation of septic blood-clot following the extraction of the tooth five weeks before death; this set up an abscess, the bronchus became obstructed, preventing free drainage, and gangrene ensued.

J. L. LIVINGSTONE, M.D., M.R.C.P.,

Junior Physician, King's College Hospital.

BIMANUAL METHOD OF LOCATING A STONE IN THE LOWER END OF THE URETER.

(With Special Plate.)

THE following case seems worthy of record as illustrating the value of the bimanual method for locating at operation a stone in the lower portion of the ureter.

A married woman, aged 41, was sent to hospital by Dr. Welsh on August 5th, with a history of severe attacks of right renal colic, which had occurred at irregular intervals during the previous four years. An *x*-ray photograph showed a shadow at the lower end of the right ureter. At the cystoscopic examination, after the injection of indigo-carmine, blue urine entered the bladder freely from the left ureter, but none escaped from the right meter. The ureteral catheter would only pass 1 cm. up the right ureter.

On August 16th, under a general anaesthetic and with the patient in the Trendelenburg position, an incision was made at the outer border of the right rectus and the ureter exposed extraperitoneally. The ureter was dilated and tortuous, but, although the ureter was easily followed to the bladder, the stone could not be felt, and it seemed possible that it might have been passed, as happens to so many stones in this position. Before doing anything further I passed the right hand into the vagina, and then, with the left hand in the wound, was able to locate the stone. It was then a simple matter, after putting on a clean glove, to cut down on and remove the stone, which was 1 cm. long and 1·2 cm. in diameter. The rough surface of the stone explained why it had not been passed. No attempt was made to suture the ureter, as I think sutures in this position may lead to cicatricial stricture of the ureter, and a suture may act as a foreign body. A drainage tube was passed down the site of the opening in the ureter and brought out at the lower end of the abdominal wound.

During the after-treatment a little urine escaped from the wound, but soon stopped, and on September 5th the wound was healed and the patient returned home.

The bimanual method was a great help, as without it the stone could not be felt either from the wound or from the peritoneal cavity, and I was reluctant to open the ureter without first feeling the stone, lest I should find that the stone had been passed. I am indebted to Dr. Gamlen for the *x*-ray photograph of the stone.

Newcastle-on-Tyne. JOHN CLAY, F.R.C.S.

FRACTURE OF RIBS CAUSED BY COUGHING.

(With Special Plate.)

THE following account of the fracture of four ribs by coughing may be worthy of record.

The patient was a doctor aged 40; he was a man of good physique, who had always been fairly healthy and had had no previous chest trouble. At Christmas time, 1928, he had influenza, and was in bed for some ten or twelve days. His chest was affected, and he had a mild pleurisy and some pseudo-asthma. About New Year time he was convalescent and was sitting in a chair when he had a paroxysm of coughing, which gave him acute pain in the left costal region. This was so bad that morphine was prepared although not used. He inhaled chloroform instead and was put to bed. He continued to have attacks of similar pain, especially at night, and his attacks of asthma continued for a fortnight. These were not relieved by adrenaline, but completely stopped after one application of ultra-violet rays.

He recovered sufficiently to go to the seaside, and was sent by Dr. Carver of Torquay to have a radiological examination of his chest. At the examination, on January 25th, he was found to have some evidence of pleurisy on the left side, and films showed that the sixth, seventh, and eighth ribs of that side had been comparatively recently fractured posterior to the mid-axillary line. He was practically free from pain at that time.

After the examination he went home, and on getting out of a bus he had an attack of coughing, which at once brought on a repetition of his previous acute pain. He arrived home in a more or less collapsed condition. On February 11th he came for a further radiological examination, and it was noted that he had—since his previous visit—fractured the ninth rib in much the same line as the other three.

The clinical examination showed no evidence of tumour or other pathological condition of bone tissue, but there was delayed resolution of the lung condition, which persisted until the beginning of April.

He was examined again recently (July) and appeared fit and well. Callus was forming around the sites of fracture.

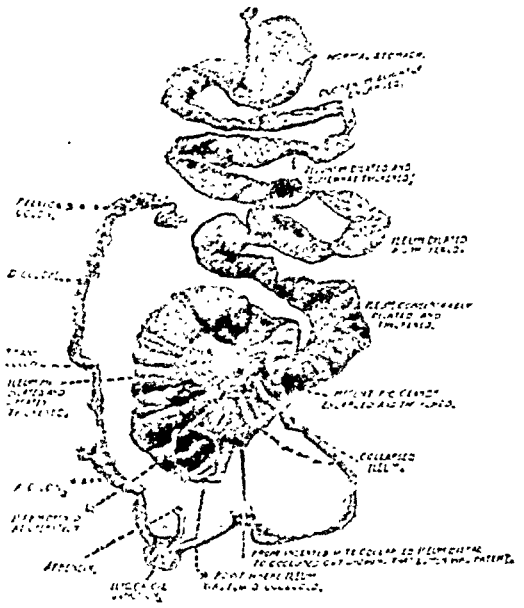
Torquay. BASIL T. HALLIWELL, M.B., Ch.B.

CONGENITAL OCCLUSION OF THE SMALL INTESTINE.

THE report by Dr. Bernard Shea, on September 24th, 1927 (p. 549), of a case of congenital occlusion of the small intestine prompts me to place on record another instance of this interesting condition, with an illustration in which the main features are so clearly demonstrated that any written description would appear to be unnecessary.

On February 19th, 1925, a Chinese male infant was admitted to the District Hospital at Ipoh with an extremely distended abdomen, and a history of not having passed meconium since birth. The patient had been seen by a private practitioner, who had attempted bowel lavage; this, however, brought away nothing but mucus.

Examination revealed a perfectly patent anus, and a small rubber catheter passed easily into the rectum.



An exploratory laparotomy was performed, and an enormously distended coil of ileum presented. This was delivered. It was found that the ileum was occluded, as shown in the accompanying photograph. An opening was made in the distended bowel, and an enormous quantity of meconium evacuated. It was found impossible to perform any type of anastomosis. The opened ileum was sutured to the abdominal parietes, and continued discharging meconium until the following day, when the infant died.

Post-mortem examination confirmed the operation findings, and the entire gastro-intestinal tract was removed, preserved in formalin, and photographed.

C. BERGOYNE PASLEY, F.R.C.S.I.,
Chief Surgeon, Federated Malay States.

EXTREME CARDIAC OEDEMA WITH RECOVERY.

THE following clinical details may be of general interest in view of the satisfactory results in an extreme case of cardiac oedema which followed the exhibition of the compound digitalis pill when other treatment had failed.

An infantryman, now aged 36, suffered from bronchitis during and after the war. In 1921 the attacks became more frequent and rather more severe. In 1925 he began to be cyanosed and dyspnoeic, and developed clubbing of the fingers. After admission to hospital his lungs cleared up and the cyanosis disappeared. Radiograms showed peribronchial thickening, emphysema, and an increase in the transverse diameter of the heart, but he was not at this stage oedematous.

Eighteen months later (1927) he was again ill with severe cough, thoracic pain, dyspnoea at rest, and cyanosis. His heart was definitely enlarged clinically, his lungs gave a hyper-resonant note, and many rhonchi were audible on auscultation. He developed oedema of the legs and genitalia, and was treated with lobelia; his legs were tapped, the oedema subsided, and he was able to leave hospital in June, 1927.

Two months later he relapsed and was readmitted. The heart was more enlarged than before, and the pulse became irregular; there was orthopnoea, general anasarca, ascites, and oedema of the chest wall. The oedema gradually became the most prominent feature of the case; it affected his legs, thighs, abdomen, and back. Tubes were introduced into his legs. Digitalis was given and his abdomen was tapped for the first time on October 7th, 1927. For the succeeding eight months his abdomen was tapped every ten or twelve days. At first about 100 ounces were withdrawn, but as the condition progressed over 400 ounces were withdrawn at a time. The oedema spread to his arms, hands, and face. His output of urine fell as low as 10 ounces per diem. Tapping the abdomen was not followed by an increase in the output of urine. Between October and the following July the abdomen was tapped twenty-five times, and a total of over 20 gallons of fluid was withdrawn. Between May 25th and June 22nd, 1928, 1,035 ounces were withdrawn from the abdomen,

and during the same period only 519 ounces were passed per urethram; the administration of diuretin or urea was followed actually by a slight fall in urinary output. His urine, examined many times, contained only a trace of albumin and no casts.

On June 11th his abdomen was tapped: 413 ounces were drawn off and at the same time the patient was put on Guy's pill twice a day and 5 grains of caffeine citrate three times daily. His average output of urine during the preceding ten days had been 18.7 ounces. During the succeeding ten days it rose to 29 ounces. By June 30th the change in the man was very noticeable; he had developed a healthy colour and his legs were less swollen. On July 15th his abdomen was tapped once more and 354 ounces were drawn off; this was followed by a drop of 20 beats per minute in the average pulse rate, and the urinary output rose to 40 ounces.

By August 7th the patient was passing over 100 ounces per day; he was up and walking about, and said he felt perfectly fit. He ate well, and his muscles regained a firm, healthy tone. In view of the seriousness of the man's history it was decided to keep him on his treatment and under observation; he left hospital, however, against advice, on September 14th, and it is not known what treatment he received outside.

On October 23rd he was readmitted with respiratory distress, cyanosis, and ascites as bad as ever, passing an average of 16 ounces a day. His abdomen was tapped and 198 ounces withdrawn. After six days in hospital he was again put on Guy's pill and caffeine citrate. The urinary output rose from 18 to 40 ounces, and after a week to 80 and 104 ounces. The ascites did not return, and his colour became healthy. The treatment was then changed to diuretin, and the urinary output fell to 52 ounces. After seven days he was put back on Guy's pill and caffeine citrate; the urinary output rose again and increased up to 100 ounces.

In view of the failure of other diuretics, notably diuretin, and of digitalis alone, the improvement was doubtless due to pil. digitalis co., though diuresis may have been assisted by the caffeine citrate. The man has now been well for two months, is up, and goes out of doors.

The points of special interest in this case are: (1) the enormous quantity of fluid (6,603 ounces) withdrawn from the abdomen; (2) the changes which followed the administration of the compound digitalis pill; (3) the good symptomatic recovery.

For permission to publish this case I am indebted to the Director-General of Medical Services, Ministry of Pensions, and to Dr. Alexander Goodall, consulting physician, Edenhall Hospital, Midlothian.

Resident Medical Officer, Ministry of Pensions Hospital, Edenhall, Musselburgh, Midlothian.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH MIDDLESEX DIVISION.

Ante-natal and Post-natal Duties of the General Practitioner.

At a meeting of the South Middlesex Division, held on November 13th, a lecture was delivered by Dr. LESLIE WILLIAMS, entitled "The ante-natal and post-natal duties of the general practitioner."

Dr. Williams passed in review the various factors concerned in the low standard of obstetrics. The first was the erroneous lay belief that pregnancy and labour were normal physiological processes; it needed to be brought home to the public that it was only by the most thorough care *before*, during, and after labour that any guarantee of normal progress could be given. Again, there was a lack of appreciation by the public of the amount of care required of the doctor in managing a pregnancy; other factors were the inferior status of obstetrics in many educational schemes, and the lack of opportunity for post-graduate instruction and practice in minor obstetrical operations.

The patient should be examined first of all as early as the tenth week, at which time the diagnosis of pregnancy could be made with certainty, and a retroverted gravid uterus be dealt with by introducing a ring pessary which should remain until the sixteenth week. The general examination should include an investigation of the condition of heart and lungs, an inspection of the breast and nipples for abnormalities, the testing of urine, and the taking of blood pressure. The patient should be given advice about the hygiene of pregnancy, including the desirability of abstinence from coitus at the times when the first five menstrual periods would have been due, and particularly during the last four weeks of gestation; also the desirability of a restricted protein intake, the care of the teeth, the avoidance of violent exercise (including excessive motoring), and the replacement of immersion baths by shower baths during the last two weeks. The next examination might be made at the twenty-eighth week. The size of the uterus should be noted in order to determine that the pregnancy was advancing at ordinary speed. As to the size of the pelvis, the lecturer was convinced that external pelvic measurements should be replaced by an internal examination, in which an effort should be made to reach the sacral promontory and so measure the diagonal conjugate. The cavity should be explored to exclude bony abnormality or tumour, and the width and shape of the subpubic arch be palpated. The further examination should take place at the thirty-fifth or thirty-sixth week, when it was the doctor's duty to find out how the foetus lay and fitted into the pelvic brim. *This was the time to convert a breech presentation to a vertex, for at this period it was not so liable to return to a breech presentation as was the case when version was performed earlier. Further, version occasionally induced premature labour, and if this did result the child born at the thirty-fifth week had a much better chance of survival than one born earlier.* Should disproportion be suspected, the difficulty of determining the exact moment when induction of premature labour was required for just commencing overlap placed the case outside the province of the general practitioner and demanded the opinion of a specialist.

With regard to post-natal care, Dr. Leslie Williams confined his remarks to certain little complications which were often overlooked. Perineal lacerations were usually detected, but it was equally important to find any vaginal lacerations, which were in just as urgent need of repair. There was no perineal laceration without an accompanying degree of vaginal laceration that needed suture by catgut; silkworm-gut suturing alone was an incomplete line of treatment. Lacerations of the cervix formed a more difficult problem, and immediate repair under anaesthesia was an operation with which in fairness the general practitioner could not be called upon to deal. It was the duty of the practitioner to make a bimanual examination of the uterus at about the fourteenth day. If the uterus was bulky and subinvoluted, the patient should not be allowed to get up, and she should be treated by ergot. Should membrane be retained in the uterus at the time of delivery no attempt to remove this should be made, but its natural expulsion should be assisted by adoption of the Fowler position and administration of ergot. The retention of placenta was a more serious business, and except in the case of a woman suffering from shock, its immediate detachment and removal by ring forceps under anaesthesia was desirable. A largely neglected side of obstetrics was the preservation of the patient's figure, by support of the breasts by a two-tailed bandage, and restoration of tone in the abdominal muscles by massage about the eighth day of the puerperium, followed by exercises usually from the twelfth day.

Dr. Leslie Williams also called attention to the need for watching for late manifestations of sepsis (about the twelfth day). With regard, finally, to retroversion, the bulky subinvoluted uterus that retroverted after pregnancy was frequently the cause of menorrhagia, backache, and discharge. To cure this condition without operative intervention demanded early diagnosis, replacement, and maintenance of the uterus in a correct position for six months. One of the principal post-natal duties of the doctor in charge of an obstetrical case was a second bimanual examination about two or three months after delivery in order that such an abnormality as a retroversion of late onset might be detected and treated.

The lecture was followed by a discussion, in which the ante-natal scheme of the Ministry of Health was considered. The meeting was generally in agreement that if the scheme were followed it would necessitate more examinations, consultations, blood pressure estimations, and urine tests than the proposed fee—stated as 11s. 6d.—would cover.

BIMANUAL METHOD OF LOCATING A STONE IN THE LOWER END OF THE URETER.

(With Special Plate.)

THE following case seems worthy of record as illustrating the value of the bimanual method for locating at operation a stone in the lower portion of the ureter.

A married woman, aged 44, was sent to hospital by Dr. Welsh on August 5th, with a history of severe attacks of right renal colic, which had occurred at irregular intervals during the previous four years. An *x*-ray photograph showed a shadow at the lower end of the right ureter. At the cystoscopic examination, after the injection of indigo-carmine, blue urine entered the bladder freely from the left ureter, but none escaped from the right ureter. The ureteral catheter would only pass 1 cm. up the right ureter.

On August 16th, under a general anaesthetic and with the patient in the Trendelenburg position, an incision was made at the outer border of the right rectus and the ureter exposed extraperitoneally. The ureter was dilated and tortuous, but, although the ureter was easily followed to the bladder, the stone could not be felt, and it seemed possible that it might have been passed, as happens to so many stones in this position. Before doing anything further I passed the right hand into the vagina, and then, with the left hand in the wound, was able to locate the stone. It was then a simple matter, after putting on a clean glove, to cut down on and remove the stone, which was 1 cm. long and 1·2 cm. in diameter. The rough surface of the stone explained why it had not been passed. No attempt was made to suture the ureter, as I think sutures in this position may lead to cicatricial stricture of the ureter, and a suture may act as a foreign body. A drainage tube was passed down the site of the opening in the ureter and brought out at the lower end of the abdominal wound.

During the after-treatment a little urine escaped from the wound, but soon stopped, and on September 5th the wound was healed and the patient returned home.

The bimanual method was a great help, as without it the stone could not be felt either from the wound or from the peritoneal cavity, and I was reluctant to open the ureter without first feeling the stone, lest I should find that the stone had been passed. I am indebted to Dr. Gamlen for the *x*-ray photograph of the stone.

Newcastle-on-Tyne. JOHN CLAY, F.R.C.S.

FRACTURE OF RIBS CAUSED BY COUGHING.

(With Special Plate.)

THE following account of the fracture of four ribs by coughing may be worthy of record.

The patient was a doctor aged 40; he was a man of good physique, who had always been fairly healthy and had had no previous chest trouble. At Christmas time, 1928, he had influenza, and was in bed for some ten or twelve days. His chest was affected, and he had a mild pleurisy and some pseudo-asthma. About New Year time he was convalescent and was sitting in a chair when he had a paroxysm of coughing, which gave him acute pain in the left costal region. This was so bad that morphine was prepared although not used. He inhaled chloroform instead and was put to bed. He continued to have attacks of similar pain, especially at night, and his attacks of asthma continued for a fortnight. These were not relieved by adrenaline, but completely stopped after one application of ultra-violet rays.

He recovered sufficiently to go to the seaside, and was sent by Dr. Carver of Torquay to have a radiological examination of his chest. At the examination, on January 25th, he was found to have some evidence of pleurisy on the left side, and films showed that the sixth, seventh, and eighth ribs of that side had been comparatively recently fractured posterior to the mid-axillary line. He was practically free from pain at that time.

After the examination he went home, and on getting out of a bus he had an attack of coughing, which at once brought on a repetition of his previous acute pain. He arrived home in a more or less collapsed condition. On February 11th he came for a further radiological examination, and it was noted that he had —since his previous visit—fractured the ninth rib in much the same line as the other three.

The clinical examination showed no evidence of tumour or other pathological condition of bone tissue, but there was delayed resolution of the lung condition, which persisted until the beginning of April.

He was examined again recently (July) and appeared fit and well. Callus was forming around the sites of fracture.

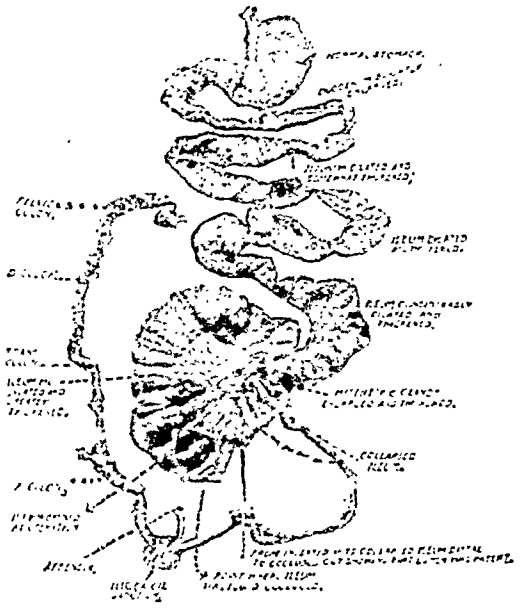
Torquay. BASIL T. HALLIWELL, M.B., Ch.B.

CONGENITAL OCCLUSION OF THE SMALL INTESTINE.

THE report by Dr. Bernard Shea, on September 24th, 1927 (p. 549), of a case of congenital occlusion of the small intestine prompts me to place on record another instance of this interesting condition, with an illustration in which the main features are so clearly demonstrated that any written description would appear to be unnecessary.

On February 19th, 1925, a Chinese male infant was admitted to the District Hospital at Ipoh with an extremely distended abdomen, and a history of not having passed meconium since birth. The patient had been seen by a private practitioner, who had attempted bowel lavage; this, however, brought away nothing but mucus.

Examination revealed a perfectly patent anus, and a small rubber catheter passed easily into the rectum.



An exploratory laparotomy was performed, and an enormously distended coil of ileum presented. This was delivered. It was found that the ileum was occluded, as shown in the accompanying photograph. An opening was made in the distended bowel, and an enormous quantity of meconium evacuated. It was found impossible to perform any type of anastomosis. The opened ileum was sutured to the abdominal parietes, and continued discharging meconium until the following day, when the infant died.

Post-mortem examination confirmed the operation findings, and the entire gastro-intestinal tract was removed, preserved in formalin, and photographed.

Chief Surgeon, Federated Malay States.

EXTREME CARDIAC OEDEMA WITH RECOVERY.

THE following clinical details may be of general interest in view of the satisfactory results in an extreme case of cardiac oedema which followed the exhibition of the compound digitalis pill when other treatment had failed.

An infantryman, now aged 36, suffered from bronchitis during and after the war. In 1924 the attacks became more frequent and rather more severe. In 1925 he began to be cyanosed and dyspnoeic, and developed clubbing of the fingers. After admission to hospital his lungs cleared up and the cyanosis disappeared. Radiograms showed peribronchial thickening, emphysema, and an increase in the transverse diameter of the heart, but he was not at this stage oedematous.

Eighteen months later (1927) he was again ill with severe cough, thoracic pain, dyspnoea at rest, and cyanosis. His heart was definitely enlarged clinically, his lungs gave a hyper-resonant note, and many rhonchi were audible on auscultation. He developed oedema of the legs and genitalia, and was treated with *lobelia*; his legs were tapped, the oedema subsided, and he was able to leave hospital in June, 1927.

Two months later he relapsed and was readmitted. The heart was more enlarged than before, and the pulse became irregular; there was orthopnoea, general anasarca, ascites, and oedema of the chest wall. The oedema gradually became the most prominent feature of the case; it affected his legs, thighs, abdomen, and back. Tubes were introduced into his legs. Digitalis was given, and his abdomen was tapped for the first time on October 7th, 1927. For the succeeding eight months his abdomen was tapped every ten or twelve days. At first about 100 ounces were withdrawn, but as the condition progressed over 400 ounces were withdrawn at a time. The oedema spread to his arms, hands, and face. His output of urine fell as low as 10 ounces per diem. Tapping the abdomen was not followed by an increase in the output of urine. Between October and the following July the abdomen was tapped twenty-five times, and a total of over 20 gallons of fluid was withdrawn. Between May 25th and June 22nd, 1928, 1,025 ounces were withdrawn from the abdomen,

and during the same period only 519 ounces were passed per urethram; the administration of diuretin or urea was followed actually by a slight fall in urinary output. His urine, examined many times, contained only a trace of albumin and no casts.

On June 11th his abdomen was tapped: 413 ounces were drawn off and at the same time the patient was put on Guy's pill twice a day and 5 grains of caffeine citrate three times daily. His average output of urine during the preceding ten days had been 18.7 ounces. During the succeeding ten days it rose to 29 ounces. By June 30th the change in the man was very noticeable; he had developed a healthy colour and his legs were less swollen. On July 15th his abdomen was tapped once more and 354 ounces were drawn off; this was followed by a drop of 20 beats per minute in the average pulse rate, and the urinary output rose to 49 ounces.

By August 7th the patient was passing over 100 ounces per day; he was up and walking about, and said he felt perfectly fit. He ate well, and his muscles regained a firm, healthy tone. In view of the seriousness of the man's history it was decided to keep him on his treatment and under observation; he left hospital, however, against advice, on September 14th, and it is not known what treatment he received outside.

On October 23rd he was readmitted with respiratory distress, cyanosis, and ascites as bad as ever, passing an average of 16 ounces a day. His abdomen was tapped and 198 ounces withdrawn. After six days in hospital he was again put on Guy's pill and caffeine citrate. The urinary output rose from 18 to 40 ounces, and after a week to 80 and 104 ounces. The ascites did not return, and his colour became healthy. The treatment was then changed to diuretin, and the urinary output fell to 52 ounces. After seven days he was put back on Guy's pill and caffeine citrate; the urinary output rose again and increased up to 100 ounces.

In view of the failure of other diuretics, notably diuretin, and of digitalis alone, the improvement was doubtless due to pil. digitalis co., though diuresis may have been assisted by the caffeine citrate. The man has now been well for two months, is up, and goes out of doors.

The points of special interest in this case are: (1) the enormous quantity of fluid (6,503 ounces) withdrawn from the abdomen; (2) the changes which followed the administration of the compound digitalis pill; (3) the good symptomatic recovery.

For permission to publish this case I am indebted to the Director-General of Medical Services, Ministry of Pensions, and to Dr. Alexander Goodall, consulting physician, Edenhall Hospital, Midlothian.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH MIDDLESEX DIVISION.

Ante-natal and Post-natal Duties of the General Practitioner.

AT a meeting of the South Middlesex Division, held on November 13th, a lecture was delivered by Dr. LESLIE WILLIAMS entitled "The ante-natal and post-natal duties of the general practitioner."

Dr. Williams passed in review the various factors concerned in the low standard of obstetrics. The first was the erroneous lay belief that pregnancy and labour were normal physiological processes; it needed to be brought home to the public that it was only by the most thorough care before, during, and after labour that any guarantee of normal progress could be given. Again, there was a lack of appreciation by the public of the amount of care required of the doctor in managing a pregnancy; other factors were the inferior status of obstetrics in many educational schemes, and the lack of opportunity for post-graduate instruction and practice in minor obstetrical operations.

The patient should be examined first of all as early as the tenth week, at which time the diagnosis of pregnancy could be made with certainty, and a retroverted gravid uterus be dealt with by introducing a ring pessary which should remain until the sixteenth week. The general examination should include an investigation of the condition of heart and lungs, an inspection of the breast and nipples for abnormalities, the testing of urine, and the taking of blood pressure. The patient should be given advice about the hygiene of pregnancy, including the desirability of abstinence from coitus at the times when the first five menstrual periods would have been due, and particularly during the last four weeks of gestation; also the desirability of a restricted protein intake, the care of the teeth, the avoidance of violent exercise (including excessive motoring), and the replacement of immersion baths by shower baths during the last two weeks. The next examination might be made at the twenty-eighth week. The size of the uterus should be noted in order to determine that the pregnancy was advancing at ordinary speed. As to the size of the pelvis, the lecturer was convinced that external pelvic measurements should be replaced by an internal examination, in which an effort should be made to reach the sacral promontory and so measure the diagonal conjugate. The cavity should be explored to exclude bony abnormality or tumour, and the width and shape of the subpubic arch be palpated. The further examination should take place at the thirty-fifth or thirty-sixth week, when it was the doctor's duty to find out how the foetus lay and fitted into the pelvic brim. This was the time to convert a breech presentation to a vertex, for at this period it was not so liable to return to a breech presentation as was the case when version was performed earlier. Further, version occasionally induced premature labour, and if this did result the child born at the thirty-fifth week had a much better chance of survival than one born earlier. Should disproportion be suspected, the difficulty of determining the exact moment when induction of premature labour was required for just commencing overlap placed the case outside the province of the general practitioner and demanded the opinion of a specialist.

With regard to post-natal care, Dr. Leslie Williams confined his remarks to certain little complications which were often overlooked. Perineal lacerations were usually detected, but it was equally important to find any vaginal lacerations, which were in just as urgent need of repair. There was no perineal laceration without an accompanying degree of vaginal laceration that needed suture by catgut; silkworm-gut suturing alone was an incomplete line of treatment. Lacerations of the cervix formed a more difficult problem, and immediate repair under anaesthesia was an operation with which in fairness the general practitioner could not be called upon to deal. It was the duty of the practitioner to make a bimanual examination of the uterus at about the fourteenth day. If the uterus was bulky and subinvoluted, the patient should not be allowed to get up, and she should be treated by ergot. Should membrane be retained in the uterus at the time of delivery no attempt to remove this should be made, but its natural expulsion should be assisted by adoption of the Fowler position and administration of ergot. The retention of placenta was a more serious business, and except in the case of a woman suffering from shock, its immediate detachment and removal by ring forceps under anaesthesia was desirable. A largely neglected side of obstetrics was the preservation of the patient's figure, by support of the breasts by a two-tailed bandage, and restoration of tone in the abdominal muscles by massage about the eighth day of the puerperium, followed by exercises usually from the twelfth day.

Dr. Leslie Williams also called attention to the need for watching for late manifestations of sepsis (about the twelfth day). With regard, finally, to retroversion, the bulky subinvoluted uterus that retroverted after pregnancy was frequently the cause of menorrhagia, backache, and discharge. To cure this condition without operative intervention demanded early diagnosis, replacement, and maintenance of the uterus in a correct position for six months. One of the principal post-natal duties of the doctor in charge of an obstetrical case was a second bimanual examination about two or three months after delivery in order that such an abnormality as a retroversion of late onset might be detected and treated.

The lecture was followed by a discussion, in which the ante-natal scheme of the Ministry of Health was considered. The meeting was generally in agreement that if the scheme were followed it would necessitate more examinations, consultations, blood pressure estimations, and urine tests than the proposed fee—stated as 11s. 6d.—would cover.

Reviews.

INDIVIDUAL PSYCHOLOGY.

Problems of Neurosis,[1] by Dr. ALFRED ADLER, will be read with interest and profit by the practitioner if for no other reason than that it is mainly concerned with descriptions and discussions of actual cases. Psycho-analysis and the various schools which later deviated from its teaching were all developments from clinical studies, and their aims were originally therapeutic. Of late years there would appear to be a tendency in these schools to concern themselves with the elaboration of theory and with the application of their principles to ancillary sciences, and as a result actual clinical problems are (in the literature) given insufficient emphasis. For this reason works entirely concerned with patients and their treatment are particularly welcome. Individual psychology is so termed because it is founded on the basic principle that the understanding of an individual can only be gained by recognizing the goals he has set himself. It stresses the self-interest motive and discovers in the striving for power, rather than in the sexual impulse, the primary conative tendency of mankind. If the goal or purpose of life is related to realities and in harmony with individual abilities the personality develops along healthy lines. But if the life-goal is no more than an egotistical desire to demonstrate a fictitious superiority, then the individual is on the road to neurosis. It is fundamental to Adler's teaching that the striving for superiority is a compensation for a sense of inferiority, and that neuroses are due to a reducible constitutional weakness or an inferior position in life. Thus, according to this view, hysterical reactions in women may frequently be interpreted as a protest against the supposed inferior position of women in general.

This book has the advantage of an introduction by Dr. F. G. CROOKSHANK, who has been much impressed by the value of Adler's teaching. In this preface it is explained that, originally to a large extent devoted to psychopathology and psychotherapy, individual psychology now stands for a psychology, a pedagogy, and a movement characterized by Wexberg as affecting life very profoundly within its radius of activity and effecting reform in respect of individual, and *therefore* social or communal life, without assumption of any political, economic, ethical, or moral doctrine. As far as this particular work is concerned, however, it does not deal with the individual psychology *movement*, but rather with the purely clinical and therapeutic problems with which it was originally concerned.

MINOR SURGERY.

MR. ZACHARY COPE is already known as the author of thoughtful and original books on surgical subjects, and his latest volume, *Some Principles of Minor Surgery*,[2] will still further enhance his well-deserved reputation. This is not intended to be a textbook of minor surgery, but stress has been laid upon certain elementary general principles which are sometimes in danger of neglect. The book is intended chiefly for the use of post-graduates, who should be able to appreciate when orthodox views have been departed from. The first chapter deals with the use and abuse of antiseptics in the treatment of wounds. The problems of war surgery focused the attention of both laboratory workers and clinicians upon this subject, about the underlying principles of which there was in pre-war days a great deal of loose thinking, not to say ignorance. The almost universal adoption of aseptic methods in civilian practice had led to a very general neglect of the study of the properties and modes of action of antiseptics. The imperative needs of the war kindled anew a deep interest in the subject which no other circumstances could have evoked, and a vast amount of research work was undertaken to the lasting benefit of surgery. Mr. Cope's admirable survey of this and of the post-war work on antiseptics by itself would more than justify the publication of this volume. Succeeding chapters deal with the principles of treatment of acute inflammation and common mistakes in the diagnosis and treatment of acute abscess. These chapters give much useful information about cases which are constantly met with in the daily routine of general practice and which not infrequently may prove troublesome if close attention is not paid to every little detail in treatment. In the chapter on diagnosis and treatment of infections of the hand Mr. Cope gives a careful summary of the views of Kanavel, and the dissertation is greatly assisted by superimposed diagrams of the hand, whereby the anatomical details upon which the whole system of diagnosis and treatment is based are clearly emphasized. The chapters on the treatment of common sprains and the ambulatory treatment of fracture are mines of information of a kind not generally included in textbooks. The treatment of retention of urine due to enlarged prostate is given a chapter to itself, and here again the teaching is clear and very much to the point. In the final chapter Mr. Cope describes his own method of performing such operations as circumcision, skin grafting, the removal of sebaceous cysts and lipomata, and so on. The book is quite short, but it is packed with information of the utmost value to the general practitioner.

In the preface to the first edition of *Principles and Practice of Minor Surgery*, the author, Dr. E. M. FOOTE, remarks that more bad surgery is performed upon the hand than upon the organs of the abdomen. That sentence was written twenty-two years ago, yet who shall deny that even yet it contains the germs of truth? That Dr. Foote's efforts to redress the balance have not been entirely without effect is shown by the production of a sixth edition[3] of his excellent and comprehensive textbook. On this occasion he has secured the collaboration of Dr. E. M. LIVINGSTON. In its present form the book consists of three parts, devoted respectively to surgical technique, surgical processes, and localized surgical treatment. The first two of these parts have been written anew by Dr. Livingston, with the exception of the chapter on bandaging. The chapters allotted to the surgical affections of the various parts of the body have been thoroughly revised by their previous author. This book is no mere catalogue of all the methods and varieties of bandaging which no one ever dreams of applying in practice; it is an attempt to cover the whole field of minor injuries and diseases which have daily to be treated in the consulting room or hospital out-patient department. It goes further than that, for quite a full description is given of the different methods of performing blood transfusion, and there is a brief but highly practical review of the various modes of inducing local and regional anaesthesia. The illustrations, nearly all from photographs, are very numerous, and on the whole are successful.

THE COMMON COLD.

INABILITY to cure a common cold has long been the subject of reproach against the medical profession by a large section of the public, especially that unthinking class which prefers to combat disease by swallowing some drug rather than to adopt the simplest preventive measure. The arts of the wizard and the sorcerer are inseparably, though perhaps unconsciously, associated with the practice of physic in the mind of the man in the street, by whom is meant in this case the man or woman without any kind of physiological or biological education. A small book[4] on the common cold by Dr. WALTER WELLS of Washington comes at an opportune time when the season of coryza and nasal catarrh has settled upon the land. The book is written for the layman, and the writer expresses himself—not without humour—in the simplest language. He does

[2] *Some Principles of Minor Surgery*. By Zachary Cope, M.S., M.B.Lond., F.R.C.S.Eng. Oxford Medical Publications. London: Milford. Oxford University Press. 1929. (Demy 8vo, pp. xi + 159; 82 figures. 10s 6d net.)

[3] *Principles and Practice of Minor Surgery*. By Edward Milton Foote, M.D., and Edward Meakin Livingston, B.Sc., M.D. Sixth edition. New York and London: D. Appleton and Co. 1929. (Roy 8vo, pp. xl + 787; 420 figures. 35s net.)

[4] *The Common Cold and Its Complications*. By Walter A. Wells, M.D., F.A.C.S. With an introduction by Hugh S. Cumming, M.D. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1929. (Cr. 8vo, pp. xiii + 225; 15 figures. 10s. 6d. net.)

not fear, nevertheless, to ask the intelligent reader to follow him through an anatomical description of the nose and its accessory sinuses and of the pharynx and larynx, with discussion on physiology. A scientific basis is thus established, and the reader should glean a rational idea of the structure and function of the nose and throat.

Besides describing the methods of infection and the predisposing local causes, Dr. Wells has much to say about diet, ventilation, and hardening. He illustrates the last point by the story of a healthy savage, who replied to a traveller unable to understand how he could expose himself to the cold almost naked, "You have no clothes on your face, have you?" "No." "Well, me all face." It is in this strain that the subject is brightened all along, and the result is readable and entertaining. In the treatment of acute coryza Dr. Wells has nothing novel to say, but he describes very well the proper treatment as it is known at present. He is sceptical about vaccines, and he has yet to see a single case of cold that was ever cured by quinine. He is well aware that colds get well spontaneously, and he countenances neither fads nor cranks. He has done good service to the public, however, by offering this essay on a minor malady which is always a nuisance and not infrequently the herald of a serious complication.

There is nothing in the book which is not known to the average general practitioner, but it will certainly crystallize his knowledge and opinions. The subject is approached and discussed in such a sensible way that it could not fail to be of use to him in dealing with the numerous patients who not only expect but demand some form of magic. The last chapter, entitled "Summary and conclusions," is a model of what patients might reasonably be expected to know and understand, and we urge practitioners to read this book and to recommend it to their patients.

MODERN TREATMENT OF VARICOSE VEINS.

LITERATURE on this subject grows apace, and we have under review, in addition to the already well-known French work *Traitement des Varices*,[1] by SICARD and GAUGIER, two newcomers, *Varicose Veins*,[2] by H. O. MCPHEETERS, and *Treatment of Varicose Veins of the Lower Extremities by Injection*,[3] by T. H. TREVES-BARBER. Moreover, a fifth edition of *The Injection Treatment of Varicose Veins*,[4] by A. H. Douthwaite, has just been issued.

The French authors, in detailing the technique of injections of sclerosing substances, favour sodium salicylate, and they include an interesting section on the circulation of blood in varices. This subject they have studied by *x*-ray observation of the movement of lipiodol in the vessels, and their insistence on avoiding muscular action for five or more minutes after administration of the solution is based on the fact that lipiodol is seen to be drawn into the deeper venous trunks when the limb is moved. They overlook the important fact, however, that the various solutions depend upon their high concentration to produce endothelial damage. It is noteworthy that these workers now practise the injection of haemorrhoids with sodium salicylate, after the application of a local anaesthetic. Furthermore, with concentrations of 10 to 20 per cent., they do not hesitate to introduce the substance into the perivenous tissue. The error of stating that the quinine-urethane treatment is not an ambulatory one is unfortunately perpetuated in this edition. The book as a whole is well worth reading, and should prove a valuable guide to inexperienced workers in the field.

Dr. McPheeters presents us with a more exhaustive treatise in which he includes a study of venous embryology, the etiology of varicose veins, and their operative or injection treatment. His section on the microscopical appearances of injected veins, and another on chronic indurated ulcers, are particularly welcome. Dr. Treves-Barber briefly reviews the etiology, pathology, and symptomatology of varicose veins, and mentions several useful methods for investigating the type of vessel which has to be dealt with. It is difficult to reconcile the statement that "embolism (after injection) can never form without infection" with the observed fact that certain drugs are far more liable to give rise to this complication than others. The book deals primarily with the technique of injecting salt solutions, but insufficient stress has been laid on the pain which this drug produces at the time of its introduction, or the severe sloughing which a slight reflux may call forth. It is strange to observe the almost fanatical zeal with which most authors uphold the use of one drug for the treatment of varices to the exclusion of all others. To the inexperienced, few books are of value in aiding them to make the correct choice. Writers would render great assistance to their readers by pointing out the fact that sugar and salt solutions are responsible for the majority of post-injection embolic complications.

In the new edition of his successful book Dr. Douthwaite records that he has given over 6,000 injections without embolic mishap; and he concludes that this experience affords sufficient testimony to the safety of one of the greatest additions to modern therapeutics. It certainly emphasizes the importance of paying attention to the nature of the sclerosing agent employed.

URINARY CALCULUS.

IN his preface to *Stone in the Urinary Tract*,[1] Mr. WINSBURY WHITE remarks that the space accorded to this subject in a work on general surgery is insufficient, and that even in a urological textbook, where more detail would be an advantage, brevity is still essential. His aim has been to produce a volume which would present the subject adequately yet in a concise form. The book is attractively written, and is of value as a record of the author's personal opinions and experiences. A noticeable feature, however, is the absence of exact details of the various operations and diagnostic procedures that are referred to. To those who are familiar with the subject this is an attraction, but for the less experienced the omission is to be regretted. Perhaps with this criticism in mind the author mentions in his preface that those who seek more information are referred to the extensive bibliography on urinary calculi at the conclusion of the volume. This bibliography gives references to the literature on urinary calculi from January, 1910, to June, 1928, and enumerates over 2,000 articles in different journals by many authors. The difficulty of the seeker after further information will be to choose which to read. In the chapter dealing with the predisposing causes of vesical calculus, Mr. Winsbury White gives a very full account of foreign bodies in the urinary bladder. Urinary calculi in children he considers fully and lucidly in a separate chapter, and he writes well on urinary calculus in relation to pregnancy. The book is profusely and well illustrated, and the reader will find in it much of interest and of value.

A STUDY OF CHRISTIAN SCIENCE.

MOST of those who read it will probably find in *Our New Religion*,[1] by the Right Hon. H. A. L. FISHER, Warden of New College, Oxford, one of the most delightful books that have been recently published. It is an examination of Christian Science "written by an Englishman mainly from American sources," or, as the publisher's note says, "a contribution from the pen of an English historical scholar to the understanding of a very curious and important development in religious history."

The volume is not a large one, and is written in a very attractive style. In its attitude and atmosphere it reminds one of Mr. Lytton Strachey's *Queen Victoria* and *Eminent Victorians*, or of M. André Maurois's *Vie de Disraeli*, but

[1] *Stone in the Urinary Tract.* By H. P. Winsbury White, M.B., Ch.B.Ed., F.R.C.S.Ed., F.R.C.S.Eng. London: J. and A. Churchill. 1929. (Roy. 8vo, pp. xii + 343; 181 figures, 2 plates. 25s.)

[1] *Our New Religion.* By the Right Hon. H. A. L. Fisher. London: E. Benn, Ltd. 1929. (5½ × 8½, pp. 191. 6s.)

it is a serious study of an interesting personality and of a remarkable phenomenon. Mr. Fisher divides his book into three chapters, "The Prophetess," "The Creed," and "The Church." The first as a narrative is far more interesting than most short stories, and the other two are, in their different way, equally absorbing. All abound in the most brilliantly apt and telling phrases, many of which it would be a delight to quote were it not that, like most gems, they are best appreciated in their appropriate setting. Few stories can better illustrate the growth of a legend in spite of the most complete evidence of its falsity, or the amazing development "upon the lines inaugurated by Mrs. Eddy, of solid business trusts framed to supply, upon terms profitable to their promoters, a stock of popular consolations and remedies to the vulgar." It is delightful to discover that "obesity is an adipose belief in yourself as a substance," and to read the testimonies given at a Christian Science service in a London church.

"A well-dressed young lady rose at once to express her gratitude to the church for these Wednesday morning meetings, and also for the very remarkable manner in which, during a recent gale in the Bay of Biscay, she had been, through science, preserved from sea-sickness. Then followed a handsome confession of error. An elderly lady had been hit in the cheek by falling timber. There was pain. There was swelling. How were these things possible? The elderly lady remembered that she was in error. The blow upon her cheek had, owing to the law of association of ideas, reminded her of a similar but more serious accident which had befallen her father. He too had been struck by falling timber, and had in consequence lost the sight of one eye. It was undoubtedly an error to conjure up this depressing memory of an injured parent, for when, by a mental effort, that memory had been expelled, the swelling by degrees abated. Another lady observed that she had always been greatly impressed by Mrs. Eddy's observation that accidents are unknown to God. Not long ago she had spilt some methylated spirit. There was an alarming blaze of fire, and at first it looked very much as if an accident had occurred; but then she recollected how the dear leader had said that there were no accidents, and from the moment that true thought came into her mind the fire died away, and she was able, by stamping upon it, to extirpate what remained."

Mr. Fisher's final analysis of Christian Science, so-called, with its core of truth, its metaphysical absurdities, its contradictions of the essentials of the Christian faith, its ousting of the virtues of humility and compassion, its main appeal to the cheerful, the well-to-do, and the neurotic, together with its regard for the dollar and alliance with business ability and acumen, is a very brilliant piece of work; and we believe that a large number of members of the medical profession will like not only to read, but to possess, his book.

NOTES ON BOOKS.

THE first three volumes of the thirty-ninth series of the well-known quarterly *International Clinics*[11] comprise a large number of readable and instructive articles on various subjects by well-known writers. The first volume contains three communications by Professor Lewellys Barker, including one of particular interest on chronic alcoholism and methods for preventing the abuse of alcohol; an essay on the bacteriophage by Dr. F. d'Hérelle, now professor of bacteriology at the Yale School of Medicine; and papers on the specific prevention and treatment of poliomyelitis by Dr. Simon Flexner of New York; biomicroscopy as a clinical aid to diagnosis in ocular disease by Dr. Harvey E. Thorpe of Pittsburgh; hyperlipochromia, otherwise known as carotinaemia or xanthosis cutis, by Dr. Hugh S. Stannus of London; and pernicious anaemia by Drs. I. W. Held and A. Allen Goldbloom of New York. The second volume includes papers on congenital and developmental aneurysms by Drs. Parkes Weber and O. B. Bode, periodical physical examination by Dr. Harlow Brooks of New York, roentgenographic visualization of the coronary arteries in normal and pathological hearts by Dr. Wendell E. Boyer of Germantown, Pa., and manners and morals in medicine by Professor Lewellys F. Barker. The third volume contains articles on the standardization of biological products by Dr. J. H. Burn of London, the technique of intravenous medication by Dr. William H. Deaderick of Hot Springs, Arkansas, the old and new in medicine by Dr. James J. Walsh of New York, the use of aeroplanes in surgical cases by the late Dr. Tuffier, and British pharmacy as a profession by Mr. J. P. Gilmour, editor of *the Pharmaceutical Journal*. Besides original articles the volumes contain reviews of recent literature.

[11] *International Clinics.* Edited by Henry W. Cattell, M.D.Philadelphia. Thirty-ninth series. London: J. B. Lippincott Company. 1929. (Med. 8vo, vol. i, pp. viii + 303, illustrated; vol. ii, pp. vii + 305, illustrated; vol. iii, pp. viii + 308, illustrated. 12s. 6d. net per volume.)

In *Anatomy and the Problem of Behaviour*[12] Mr. COGHILL gives us the substance of three lectures delivered by him at University College. The research was developed from the work of the Herricks on comparative neurology, and serves to supplement the ideas of Child on the origin of the nervous system and of Arien-Kappers on neurobiotaxis. The first lecture is devoted to the development of behaviour and its anatomical explanation in a typical vertebrate, the second to dynamic antecedents of neural mechanisms, and the third to the growth of the nerve cell and the interpretation of behaviour. The research was carried out on amblystoma; it is an excellent piece of work well presented.

Dr. J. L. KANTOR's book on *The Treatment of the Common Disorders of Digestion*,[13] which was noticed on its first appearance in our issue of October 4th, 1924, has now reached its second edition. In revising his material the author has rearranged the sequence of his chapters in order to lay greater emphasis on disorders of the colon. A number of new illustrations have been added.

The first instalment of Dr. VALENTINO FACCHINI'S work on the serum diagnosis of syphilis,[14] which has just been published, is divided into two parts, preceded by an historical introduction. In the first part the author discusses the technique of the Wassermann reaction and the serological questions connected with it. The second part is devoted to a study of the importance of the Wassermann reaction in clinical medicine, including its behaviour in the various stages and forms of syphilitic infection. Five subsequent instalments of this work are promised.

Dr. FRITZ CALLOMON'S work on non-venereal diseases of the external genitals,[15] of which a revised and enlarged second edition has been sent us, will appeal not only to the urologist, venereal specialist, and dermatologist, but also to the general practitioner. The subjects discussed include the localization of common dermatoses, such as eczema, psoriasis, lichen and urticaria in the genital area, various mycoses, herpes, acute or chronic forms of genital ulceration due to various causes apart from sexual congress, non-gonorrhoeal urethritis, diseases of the testis, epididymis, and inguinal lymphatics of non-venereal origin. The text is accompanied by numerous excellent illustrations, some of which are in colour. A bibliography of recent literature is appended.

The second edition of Mr. I. F. HENDERSON and Dr. W. D. HENDERSON'S *Dictionary of Scientific Terms*,[16] giving the pronunciation, derivation, and definitions of biological, botanical, zoological, anatomical, cytological, embryological, physiological, and some bacteriological and palaeontological words, adds about 1,500 new terms to the 10,000 contained in the first edition, noticed in these columns on its appearance eight years ago. But in spite of the additions the number of pages is rather less and the price somewhat reduced.

[12] *Anatomy and the Problem of Behaviour.* By G. E. Coghill. London: Cambridge University Press. 1929. (Demy 8vo, pp. xii + 113; 52 figures. 7s. 6d. net.)

[13] *The Treatment of the Common Disorders of the Digestion.* By John L. Kantor, Ph.D., M.D. Second edition. London: H. Kimpton. 1929. (Med. 8vo, pp. 297; 83 figures. 25s. net.)

[14] *La Sierodiagnosi della Sifilide.* Dottrina tecnica e valore practico con speciale riguardo alla clinica medica. I. Per Dr. Valentino Facchini. Bologna: L. Cappelli. 1929. (Sup. roy. 8vo, pp. viii + 520. L.60.)

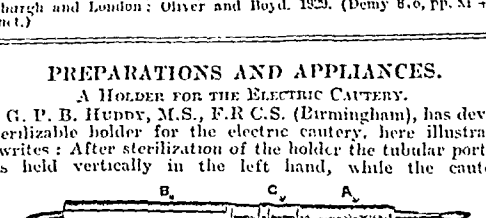
[15] *Die Nichtvenerischen Genitalerkrankungen.* Von Dr. Fritz Callomon. Zweite Auflage. Leipzig: G. Thieme. (6½ × 10, pp. xiii + 201; 62 figures. M 18.)

[16] *A Dictionary of Scientific Terms.* By I. F. Henderson, M.A., and W. D. Henderson, M.A., B.Sc., Ph.D., F.R.S.E. Second edition, revised. Edinburgh and London: Oliver and Boyd. 1929. (Demy 8vo, pp. xi + 252. 16s. net.)

PREPARATIONS AND APPLIANCES.

A HOLDER FOR THE ELECTRIC CAUTERY.

MR. G. P. B. HUDDY, M.S., F.R.C.S. (Birmingham), has devised a sterilizable holder for the electric cautery, here illustrated. He writes: After sterilization of the holder the tubular portion, A, is held vertically in the left hand, while the cautery,



suspended by its lead, is lowered into it by an assistant. While still thus suspended the second portion, B, which is opened on its hinge and is held in the right hand, is now closed round the portion of the lead which projects from A, and is then locked into A; B serves to lengthen the holder, to fix the cautery in position, and to cover the end of A, which may have been touched accidentally by the cautery during its insertion. The

slide, C, covers the junction of A and B, thus ensuring asepsis. When in use the cautery is held by A, and the lead is maintained taut by a nurse so that it does not come in contact with the surgeon's gown. The apparatus is simple and convenient. Asepsis is ensured, and the cautery can be used with safety within, for example, the peritoneal cavity or bladder. The assistant, when preparing other instruments for operation, can put the cautery enclosed in its holder in readiness for instant use. The instrument was made for me by Chas. F. Thackray, Park Street, Leeds.

A New Antiseptic.

Quinanil is a new antiseptic prepared by Messrs. British Drug Houses. The compound has the chemical name of 2 (p-dimethylamino-anil) 6 methyl-quinoline metho-chloride, and it is No. 48 of a series of compounds described by Browning and his co-workers (*Proc. Roy. Soc.*, B. 100, 293, 1926). Its antiseptic properties have recently been submitted to bacteriological and clinical tests (Armitage and co-workers, *Lancet*, 1929, ii, 968). The drug was tried as an external antiseptic, and for irrigation of the bladder, and very favourable results were obtained. It was also tried intravenously for treatment of septicæmia, but the results were inconclusive.

Palatable Ephedrine.

"Elixoid" ephedrine compound (Messrs. Burroughs Wellcome and Co.) is a preparation which contains gr. 1/4 ephedrine hydrochloride in each fluid drachm. It is a pleasantly flavoured preparation, suitable for administration to children or to fastidious adults. The value of ephedrine in asthma and hay fever is well established, and it is also useful in mild and moderate cases of whooping-cough.

Glucose for Medical Use.

Medicinal glucose (Messrs. British Drug Houses) is a pure glucose suitable for all medicinal purposes. In particular, it is suitable for intravenous injection, a form of administration of glucose which has become of increasing importance in recent years. The preparation is a white, freely soluble powder.

SOME WINTER MOTORING SUGGESTIONS.

It may be useful at this time of the year to draw attention to some of the precautions that must be taken in respect of the motor car if it is to give the same continuous, dependable service as it does during the warmer months. These precautions may be broadly divided into two classes—namely, those that are necessary when the vehicle is in use and those that must be taken when the car is put away for the night.

Precaution of Damage from Frost.

As periods of sharp frost may be expected at any time it is necessary to prevent the engine-cooling water from freezing, otherwise there is a risk of the cylinders becoming cracked or the radiator springing a leak. The precaution usually recommended is to drain off the water when the car is put away for the night and to fill it up again the next morning. Where this course is adopted it is not sufficient (as is pointed out in a useful circular just issued by the Automobile Association) simply to empty the water out of the radiator; an attempt should also be made to clear the engine water jackets and the circulating pump, and on these drain cocks are often provided nowadays for this purpose.

For medical practitioners who are likely to require the use of their cars at any hour of the night as well as during the day this precaution is, of course, out of the question, and some other method must be adopted. Opinions are divided as to the relative efficiency of the alternatives. Thus the Automobile Association gives first place to a well-heated garage, or to some electric or other apparatus which gives out sufficient heat to maintain the engine at a temperature above the freezing point. As against this, one of the leading insurance companies, which has lately issued a useful chart of precautions against freezing, considers that heating devices in the garage are often inadequate to provide protection against severe frost, and states that last winter a large proportion of the damage from frost occurred in garages in which some form of heating device was employed. This company regards the addition of an anti-freezing medium to the engine-cooling water as the more efficacious method.

Those who prefer garage- or engine-warming devices will find a wide choice at their disposal, ranging from a small electric or oil heater in the form of a miner's safety lamp, intended to be hung under the bonnet between the radiator and the engine, to large stoves, such as are used for heating greenhouses. The great point to remember is that no naked light or heat should be used in a garage.

As anti-freezing media pure glycerin or methylated spirit are both recommended, a mixture consisting of three parts of either medium to seven of water remaining liquid even at a temperature of 12° F. The medium must not simply be added to the water in the radiator, but the latter must be drained off and replaced by the necessary quantity of liquid mixture. Glycerin has the advantage that it does not evaporate, so that the cooling system can be replenished, when necessary, with water only; when, however, methylated spirit is used, any replenishment must be by mixture, and not water only.

On the Road in Cold Weather.

Turning now to the special points to which attention must be given to keep a car in good running condition in cold weather, the first to be mentioned is that of the oil used for engine lubrication. Most of the oil firms recommend the use of a slightly thinner oil in winter than in summer. A postcard to the makers of the brand of oil generally used, mentioning the name and horse-power of the particular car, will quickly bring a reply suggesting the most suitable grade of oil for winter use.

Use a Radiator Muff.

During very severe weather the water in the radiator may freeze while the car is in motion or while it is left standing for short periods. Many of the latest cars have shutters fitted in front of the radiators to maintain the cooling water at the most efficient temperature for the engine. Even so, it is advisable to fit the radiator with one or other of the many varieties of muff that are now on the market, care being taken not only to drop the flap when the car is to stand in the road for some time, but to raise it when the car is again started: otherwise there is a risk of the water boiling and the engine overheating.

Overloading the Battery.

Another winter motoring precaution that calls for mention relates to the care of the battery employed in connexion with the lighting and starting installation. Despite all precautions, engines are more difficult to start in winter than in summer. Hence, before bringing the electric starter into use after a car has been standing in the garage all night, the engine should be turned over several times by the starting handle, in order to free the pistons within the cylinders. If this is not done there is a risk of the accumulators being quickly discharged to an extent greater than can be replaced by ordinary engine running. Special attention must also be given to the battery to see that the terminals are kept clean and that the level of the acid above the plates is maintained.

When the engine is put into motion after standing all night it is advisable to let it run slowly for a few minutes in order that its parts may warm up and so give reliable running when the journey has been actually started. The numerous fatalities that have occurred render it advisable to utter a warning against the risk of running an engine in a closed garage; the door or doors and windows should always be open in order to allow of the dissipation of the dangerous exhaust gases.

Fog and Snow.

Foggy weather is always dreaded by motorists, but there are now on the market a number of spotlights and fog-penetrating screens that can be fixed to the front of head-lamps, which to a certain degree facilitate driving through fog. For driving over snow-covered roads the use of specially designed chains round the tyres may be recommended.

C. J. W.

CANCER IN WESTMORLAND:

AN INVESTIGATION INTO ITS INCIDENCE, EPIDEMIOLOGY, AND ECOLOGY.

(Preliminary Note.)

IN view of the important and timely step taken by the *British Medical Association* in calling for the co-operation of every medical practitioner throughout Britain to help in a mass inquiry into the incidence of cancer, we beg to submit the following note.

Two years ago, fully appreciating the importance of cancer research work carried out in hospital, pathological laboratory, and special institution during the last half century, yet aware that no definite knowledge of cancer causation had been reached, we resolved that the time had come when health officer, country doctor, and veterinary surgeon should take up their share of the burden of scientific research.

Impressed by Dr. Louis Sambon's cancer investigations in the American tropics, in Iceland, Holland, and Italy, we offered him the opportunity he was seeking for testing findings hastily gleaned abroad by means of a thorough *medico-zoological survey* of an entire county at home. The county of Westmorland seemed ideal for the purpose. In it, certainly, the incidence of cancer is only moderate, as compared with other parts of Britain, but the *region offers* very favourable conditions for epidemiological and ecological investigations on account of the greatly diversified nature of its physiography, geographical structure, flora, and fauna.

The recent history of the elucidation of the etiology of many tropical diseases, such as malaria, plague, trypanosomiasis, and typhus by the epidemiological method is highly instructive, and the part played by Sambon in this work is known.

A special commission—"The Westmorland Field Commission for Cancer Research"—was formed under the able chairmanship of Sir Samuel Haslam Scott, Bt., of Windermere, and every assistance was supplied, not solely by the physicians of the county, who are unanimous in their support, but by the public generally, who have taken the keenest interest in work carried out under their very eyes. The *results* obtained are so striking and important that we deem it a duty to make some of them known long before the final and elaborate report can be published.

Dr. Sambon's findings are so greatly at variance with some of the views at present held by the majority of experts the world over, that we feel bound to make our *position quite clear*. In the first place, it was decided to discountenance all theories concerning causation, and to *ignore*, for the time being, all views based solely on clinical or pathological data. It seemed better to approach the disease as if totally unknown and collect only sheer facts.

From the first Dr. Sambon insisted on a complete survey of the entire county, and on a careful statistical study of its cancer incidence throughout the whole period of available registration, which runs almost to a century. To some of us the task seemed far too ambitious, but it has been accomplished with extraordinary care. Indeed, owing to the nature and importance of the results, Dr. Sambon decided to extend his researches to the Isle of Wight and to the island of Arran, in order to obtain confirmation of our findings from other various isolated areas south and north. In this extension of his work Dr. Sambon received the support and assistance of Dr. J. Fairley and Professor J. R. Currie, the respective health officers of these islands.

Recently two international cancer conferences have been held, one in America in the autumn of 1926, the other in London in the summer of 1928. More than a hundred delegates took part in the conference convened at Lake Mohonk, New York, by the American Society for the Control of Cancer. At the end of the meeting the following statement was issued:

"Although the cause of cancer is not completely understood, it may be accepted that for all practical purposes it is not contagious nor infectious."

The London conference, organized by the British Empire Cancer Campaign, was attended by about three hundred delegates and members representing eighteen countries. Here again, with very few exceptions, the parasitic theory was discredited. Professor James Ewing of the Cornell Medical School, New York, said:

"The theory of a universal cancer parasite stimulating the cell to incessant growth is the most popular explanation of the cancer process, and seems to satisfy many minds. It must be ruled out of court on the ground of no evidence. It raises more questions than it solves, and is inconsistent with the known facts about many tumours."

To these views must be added the very general belief that cancer is a local disease.

Our investigations indicate very forcibly that we are confronted with a systemic infection characterized by long latency and exhibiting varied local manifestations, determined in type and site by the most diverse physical, chemical, mechanical, or animate irritants. Insidious invasion, long quiescence, complexity of secondary factors, muteness of symptoms, and protean nature of manifestations are the peculiar features which have baffled inquiry so persistently.

Dr. Sambon believes that "cancer" is brought about by the activities of an exceedingly minute endocellular parasite strictly adapted to its specific cell host. He points to *Rickettsia*, the germ of typhus, which inhabits almost exclusively the endothelial cells of the capillaries, giving rise to marked defensive *proliferation*, the *formation* of intravascular overgrowths (Fraenkel's "nodules"), and metastases. He looks upon the gross tumour—the actual "cancer"—as a late, often fatal, manifestation of the cancerous infection not unlike the gumma in tertiary syphilis. As in tuberculosis, so also in cancerosis, the specific germ appears to be universally prevalent and of wide zoological distribution.

These rough statements are supported by a wealth of carefully ascertained facts.

The parasitic, unobtrusively infective nature of the disease is attested by its peculiar distribution both in time and place. The cluster-distribution of cancer cases, already perceived by Sambon in his previous researches abroad, has been amply confirmed in Westmorland. We have here hamlets and villages which have remained totally free during the whole period of registration, while others, of equal age, size, and population, have been, at one time or other, heavily punished. Our spotted large-scale ordnance maps show villages with one, two, or more separate clusters, while others are more or less uniformly affected; others, again, show heavy infestation in one portion of the village, while the other has remained almost or entirely immune. What we have said of villages applies equally well to terraces and single houses. We have found single houses with numerous family cases, others with several cases occurring in non-related successive occupiers. An important fact, clearly elicited by our village survey, is the frequent occurrence of the disease in husband and wife, not "coition cancer," as wrongly named by some, but conjugal house infection.

Perhaps the most striking, the most interesting discovery our investigations have elicited is the great prevalence of all types of malignant and other neoplasms in animals. We have met with cancer in all kinds of wild and domestic animals, in pet animals, and in animals used as food. We might mention horse, cow, sheep, hog, cat, dog, hedgehog, rabbit, vole, rat, mouse, fowl, turkey, goose, owl, canary, and toad. Fowls of all varieties (Leghorns, Wyandottes, Plymouth Rocks, Bantams, Anconas, Rhode Island Reds in our series) are particularly liable, and we have noticed small outbreaks of the disease in certain poultry flocks similar to the cage epidemics of rats and mice mentioned by Borrel in France and by Gaylord in America. This unexpected, remarkable prevalence of the disease in all kinds of animals opens up a wide field of possibilities which we are already exploiting.

In his lectures at the London School of Hygiene and Tropical Medicine, and in his epidemiological papers, Dr. Sambon has repeatedly stressed the importance of a full knowledge of the zoological distribution of disease. With-

out a knowledge of the animal sources of infection it is not possible to understand, far less to control, outbreaks of disease in man. A memorable example is that of Russian artillery sent to destroy all the inhabitants of a plague-stricken border village in order to stay the epidemic. The unfortunate people were sacrificed, but no one troubled about rats, and the disease soon spread like wildfire. Is it not known now that many cases of tuberculosis are not of human source, but, on examination, prove to be of either bovine or avian type?

Another important fact, elicited by our researches, is the discovery of a specific dermatosis in fowls suffering from malignant growths. This cancroderm, first noticed by Dr. Sambon in Westmorland and Cumberland fowls, was recognized soon after by him, Dr. Sprott of Appleby, and Dr. Holroyde of Windermere, in a woman of Colby affected with sarcoma of the elbow, who had spent her life in breeding chickens. Her forehead presented a corona of the peculiar pigmented nodules, others occurred on nose and cheeks; one of the nodules on the right side of her nose had assumed the rodent ulcer type. On section the fowl nodules proved to be tiny sarcomatous growths. The recognition of an indubitable cancroderm in fowl and man is therefore of special interest and, surely, a proof of the systemic nature of cancerosis.

A subject to which Dr. Sambon, a helminthologist, has given particular attention is that of the part played by animate irritants in determining the site and type of neoplasms. He holds that the cancer germ is as common, and as universally distributed, as the bacillus of tuberculosis, but that, as in the case of the latter disease, few people succumb to, or suffer from, its grave manifestations, and that these invariably are brought about by some local irritant—such as traumatism, for instance, or a syphilitic lesion, or some helminth.

The part played by certain parasitic worms—by *Opisthorchis felineus*, in favouring hepatic cancer among the Lettish fisherfolk of the Baltic coast (Askanazy), by the strobilocercus of *Hydatigera taeniaeformis* in producing liver sarcoma in rats (Borrel), by *Gongylonema neoplasticum* in bringing about gastric carcinoma in rats (Fibiger)—is well known. All these are instances in which helminths figure as necessary factors in the development of certain types of neoplasm, and more especially in determining the organ involved, which, of course, invariably is their habitat. Many older examples might be quoted from Egypt, such as cancer of the urinary bladder induced by von Siebold's schistosoma (*S. haematobium*), and cancer of the rectum by Sambon's schistosoma (*S. mansoni*). To these Sambon has added several others of considerable interest—such as *Muspicea borrelli*, *Hepaticola gastrica*, and the tiny mite *Psoergates simplex*—all internal parasites of rodents whose role as coadjutants in the production of cancer has been fully confirmed. In some of our cancerous fowls a very minute sarcosporidium was found in the subjacent muscles, and in an Elterwater toad with large tumour of the right front leg the sarcomatous growth was found to have developed over a massive mycelial infestation.

Finally, we must mention the ecological investigation undertaken. It is probably the first time in the history of European medicine that an ecological survey has been applied to epidemiological work. Dr. Sambon, who is a naturalist as well as a physician and archaeologist, has left no stone unturned in his comprehensive study of cancer conditions in the English Lake District. The surroundings of houses where cancer had recently occurred have been thoroughly scrutinized. Besides, inasmuch as findings seemed to suggest possible carriers, or intermediary hosts, wild and domestic animals have been examined for a complete knowledge of their external and internal parasites. This work has brought to light many interesting facts, such as the great prevalence of tuberculosis of avian or bovine type in rats infesting stables and breweries, but it would take too long to detail the full extent of the work carried out.

The zoological work has been greatly advanced by members of the British Museum (Natural History Department) and the Manchester Natural Museum, and all animal neoplasms have been examined by Sir Lenthal Cheatle and other expert pathologists in England and Scotland. Plant tumours have not been neglected, and our collection of phytological specimens includes some very instructive types. Anyone who has read Dr. Sambon's previous cancer reports will easily understand what a wide field has been covered under his able guidance.

Signed on behalf of the medical men of the Westmorland Field Commission for Cancer Research,

COLIN MCKEAN CRAIG, O.B.E., M.D., D.P.H., Surgeon, Westmorland County Hospital, Kendal.

GERALD HOLROYDE, *M.C.*, M.R.C.S., L.R.C.P., Windermere.

MEDICAL USES OF RADIUM.

REPORTS FROM RESEARCH CENTRES.

UNTIL 1921, when the Medical Research Council, for the purpose of promoting research upon the therapeutic properties of radium, distributed on loan among various research institutions the stock of radium salts that had been entrusted to it by His Majesty's Government, there had been no systematic and comprehensive study in this country of the problems and methods of radium therapy. Up to that time the clinical use of radium was almost wholly empirical, and the results obtained were of doubtful value. How much this general situation has been transformed in the eight years during which the investigations thus promoted by the Medical Research Council have been in progress may be realized from a study of the reports prepared each year since 1924 by the Council's Radiology Committee, in which are summarized the results of the research work that has been carried out by the institutions working under its supervision. In the report[1] just issued there is evidence of continued advance in the technique of applying radium to the various parts of the body, but it must be emphasized that development in technique does not necessarily imply therapeutic advance. Much time must obviously elapse before statistical proof is available about the value of any particular therapy in a disease so likely as cancer to recur after some years.

The Radiology Committee believes that the chief danger of the future lies in the possible assumption that radium can be applied by any medically qualified person, irrespective of whether he has had previous training in the use of this form of treatment. While, however, it is true that there is no special difficulty in applying radium superficially, or even in the insertion of radium into the body, these procedures constitute only a small part of radium therapy. Development of radium therapy on national lines demands, therefore, the immediate initiation of a scheme of training designed to fit more men and women for the highly specialized type of work that is involved.

Cancer of the Breast.

At the Middlesex Hospital the best results in the treatment of primary cancer of the breast, apart from the ulcerated cases, where greater surface intensities can be applied, have been obtained by radium applications at a distance of several centimetres, though by using greater quantities of radium (1 to 4 grams) at greater distances it seems possible that the results would be better. Among 13 of 33 patients with nodular recurrences the nodules disappeared after treatment, but in most of the patients with nodular or supraclavicular recurrence other signs of disease soon appeared, with a fatal issue, and it has therefore been difficult to estimate the results of the local treatment of such advanced recurrent cases. For small superficial nodules three or four applications of gamma rays only,

[1] Medical Research Council. Special Report Series, No. 141. Medical Uses of Radium: Summary of Reports from Research Centres for 1928. H.M. Stationery Office. 1929. Price 1s. net.

from an apparatus containing 10 millimetres to the square centimetre, half a centimetre away, for four to six hours, were usually enough, the interval between the exposures being three weeks. Larger nodules of deep origin have been treated from two centimetres distance, but recurrence has occurred, and probably greater distances would be better. It has been found that if, in the course of deep radium therapy of breast cancer, a suberythematous dose is given through the area of disease, wide variations in quantity and concentration, distance and time, have led to a satisfactory issue, especially if the dose has been repeated two or three times at three-weekly intervals. Where the disease has remained localized long enough to be observed satisfactorily, the failures have usually been traced to inadequate dosage or omitting to give more radiation after apparent cure. The results at the Middlesex Hospital do not support the view that the best method of treating breast cancer is by small doses for a long time, as in tongue cancer.

The majority of cases of breast cancer at St Bartholomew's Hospital were treated by inserting radium needles only, screened by 0.5 millimetre platinum, and by only one application; for irradiating the parasternal glands the needles are placed very obliquely in the intercostal space at some distance from the sternal margin, so that the points enter the anterior mediastinum beneath it. A good result has been obtained in 45 out of a total of 67 patients treated since 1924, including 12 patients out of 26 whom surgery could not have helped.

In the 12 cases treated during the year in Dublin five needles (0.4 millimetre platinum, 0.3 millimetre gold), each containing 5 to 10 mc. radon, were embedded circumferentially round the primary growth and left *in situ* until 2 mc. per cubic centimetre of neoplastic tissue were dissipated. The axilla and supra- and intra-clavicular regions were treated by deep x rays, and in all the cases treated the immediate result has been retrogression of the growth and of the enlarged glands.

Cancer of the Uterus.

As in previous years, the results of treatment have been grouped in three subdivisions—namely, operable, borderline, and inoperable—though it is probable that as some centres adopted only the first and last classification the number of borderline cases enumerated in the total results is an underestimate of the actual numbers treated. Of 579 patients with inoperable disease treated at the centres since 1921, only 139 are now living. The results in patients with borderline disease are somewhat better, 27 being alive of a total of 65 treated, and of 39 with operable disease 29 are living. As before, better results are being obtained by those centres which have adopted the Stockholm technique, or some modification of it, than by others. From a survey of the quantity and arrangement of the radium treatment given at most of the centres for advanced cases it is evident that some parts of the area of spread cannot possibly get anything approaching a lethal dose of radiation, though other parts may be dealt with quite effectively.

At St. Bartholomew's Hospital a modification of the technique worked out at the Brussels Radium Institute has been adopted. Intra-abdominal insertion of radium is usually carried out about six to eight weeks after the vaginal application—that is to say, when the local external growth has disappeared and all ulceration healed. The two applications are not made simultaneously, on the grounds that so long as there is an infected area in the cervix and fornices it may be wiser to do nothing to the abdomen and parametrium which might lower the resistance to that infection. With the patient in the Trendelenburg position, the abdomen is opened and an examination is made of the liver, aortic glands, the pelvic organs, and the iliac glands. The intestines are packed off and the uterus is pulled forward; the needles, screened by 0.5 millimetre platinum, are now inserted through the parietal peritoneum, leaving only their eyes protruding. The suture from the tube is put through a small portion of the peritoneum below the needle eye, and a knot is tied over a glass bead to prevent cutting through the thin peritoneal tissue. The needles are placed at a distance of 1 to 1½ centimetres from each other, starting at one sacro-iliac synchondrosis and ending at the corresponding joint of the opposite side. In addition, four or possibly more needles are placed in front of the broad ligaments, in the hope of eradicating the disease from the obturator glands. The ends of the sutures having been tied together and pushed down into Douglas's pouch, the abdomen is sewn up and the radium left *in situ* for seven days, at the end of which it is again opened and the radium removed.

The modification of the Stockholm technique used at the Marie Curie Hospital, London, was described in our issue of November 30th (p. 1025).

The reports from University College Hospital suggest that it is impossible to differentiate between the sequelae of radium treatment and the normal ravages of malignant disease, and in addition to the sequelae to which attention was drawn in previous reports—namely, persistent pyrexia, pyometra, pelvic abscess, pelvic peritonitis, fistulation, and dissemination of growth—mention is made in this report of sinuses and shortening of the vagina. Some account of this complication, which is liable to arise after an exposure to doses larger than 3,000 milligram hours of element, appeared in our review published on August 3rd (p. 219) of the sixth report of the Harker-Smith Registrar.

In connexion with fistula formation, Cardiff, which reports this complication in 10 *per cent.* of its cases, suggests that as in practically all the patients the disease was far advanced it is probable that fistulae would have developed in a certain proportion without radiation. It is noteworthy that in the patients in whom this complication occurred the dosage had been no higher and the number of applications no greater than in patients who had not developed this complication, and the precautions as regards packing off the bladder and rectum had been the same. As, moreover, the frequency of fistula occurrence in untreated cases has been shown statistically to be higher than in the Cardiff series, there is reason to doubt whether radium properly applied has any important effect in producing this sequel. In this report it is suggested that the insertion of a self-retaining catheter, together with firm vaginal packing, seems most likely to prevent bladder fistulae in advanced cases.

Mouth and Nasopharynx.

Though the local radium treatment of cancer of the tongue is now generally looked upon as hopeful, there is considerable divergence of opinion about the best way of dealing with glands in the neck which are, or may be, the seat of growth. Treatment by block dissection, with or without the application of a radium collar or the introduction within the wound of radium needles, appears to be relatively ineffective, though the St. Bartholomew's report suggests that the best results have been obtained so far by the insertion of radium needles into the neck alone. No method has proved successful in patients with faucial growths, and the substitution of x rays has not been satisfactory, even when they have been applied before the use of radium locally. Wide differences exist in the reaction to radium therapy of growths in the upper air passages. Growths of the lips and cheeks have done well, but of the upper jaw and the skin of the nasal vestibule very badly.

The Birmingham report refers to the varying degree of success attending radiation treatment of 29 cases of epithelioma of the buccal cavity, and the results indicate clearly the benefits of early diagnosis and treatment. For the treatment of the gland fields the method advocated is by surface irradiation for eight to twenty-four days, from a collar, using about 70 to 80 milligrams of radium as 5-milligram tubes, arranged usually over one side of the neck and the opposite submaxillary region. In some of the advanced cases it is worth while to excise a mass of growth, to cut through infective tissues if need be, and then to irradiate; but where the primary growth is small and no glands are palpable, surgical excision followed by irradiation of the neck later is held to be the method of choice.

In Dublin, following the method of Dr. Todd of Bristol, intravenous injections of selenide of lead have been given some weeks after the last radium treatment, but at present the results are inconclusive.

The Larynx.

The treatment of this region is rendered difficult and dangerous by the presence of sepsis above in the mouth and nose, the recurring movements of the parts, the delicacy and sensitivity of the tissues affected, the susceptibility of cartilage to necrosis after the application of radium, and the narrowness of the passage-way through the larynx itself. In cases of intrinsic cancer the results of laryngo-fissure are so good that

at the present time the adoption of any less certain form of treatment is held to be unjustifiable. For cases in which the growth has spread to the opposite cord, or in which a growth runs round the larynx and gradually occludes the lumen, radium therapy seems to be indicated.

Oesophagus.

In the Birmingham report the treatment of carcinoma of the oesophagus by applying radium to the centre of the lumen, or by first obtaining access to the oesophagus from outside, or by inserting tubes directly into the growth with the aid of an oesophagoscope, is subjected to criticism, and a procedure is described which involves the introduction through the oesophagoscope by a trocar and cannula of three to eight radon seeds, screened by 0.3 mm. platinum. The seeds are introduced at approximately regular intervals in directions downwards and outwards at a distance of one centimetre apart around the range of the growth. So far the immediate operative results have been excellent, and improvement has resulted in every case. Insufficient time has elapsed, however, to warrant any statement about the end-results of this treatment.

Rectum.

At St. Bartholomew's high growths have been attacked by needling through the abdomen, and the upward areas of lymphatic spread have been radiated with needles or radon seeds as a preliminary to excision in operable cases or to palliation of the growth from below. Radon seeds have been further employed by direct implantation into the rectal growth without operative exposure from behind. In low growths the seeds can be inserted through the skin into the growth. For higher growths the seed introducer is inserted into the growth through the lumen of the rectum. Of 12 cases thus treated 3 died and 9 have received benefit, 4 of these being apparently free from evidence of growth. During the period 1925-27, 17 patients were treated, of whom 4 have survived respectively thirty-seven, thirty, twenty-two, and seventeen months, and are apparently cured.

In Birmingham the irradiation has been carried out chiefly by the insertion of the radium round the growth from the rectal surface, and in addition needles have been inserted into the perirectal tissue near the growth. Some degree of cross-fire action has thus been obtained, but except in low growths it has rarely been adequate. The average dose was 5,400 milligram hours, made up of 70 milligrams of radium given for seventy-six hours. All the 9 patients thus treated are still alive, but in only 2, whose growths were low down and easily accessible, has there been any improvement. Every case was advanced and surgically inoperable.

The King's College Hospital report contains details of 30 inoperable cases which were treated by the insertion of radium into the lumen of the bowel. In every case a preliminary colostomy was performed, and the quantity of radium used varied from 105 to about 35 milligrams, enclosed in platinum iridium containers 0.5 mm. thick. The duration of application varied from twelve to thirty hours. The results were, on the whole, not good, but success was hardly to be expected. An interesting feature of the series was the variation in the degree of reaction to the same dose; in some cases definite radio-necrosis resulted, and in others the reaction was unappreciable.

Bladder and Prostate.

Two methods were used at St. Peter's Hospital for dealing with growths of the bladder: in the one, applied to the ulcerative variety only, platinum needles 0.5 mm. thick containing 10 milligrams of radium bromide were inserted into the periphery of the growth outside the bladder as well as on its mucous surface; in the cauliflower type the tubes were buried in the base. In the other method the bladder was widely opened and as much as possible of the growth burnt away by diathermy; platinum needles each containing 10 milligrams of radium bromide were then inserted into the bladder wall round the base of implantation, and the bladder was drained. Of 8 patients treated by the first method, 3 died within a month of irradiation, the remainder were discharged in fair health at periods varying from three to five weeks. One of these survived three years and one two years; two who were treated in 1927 are still alive, one of them showing no signs of recurrence. The report also contains details of two cases of cancer of the prostate treated by irradiation, one of which, treated in July, 1923, showed improvement, and no sign of relapse was observed in November, 1928.

Sarcoma and Lymphosarcoma.

The sarcomata appear to offer a good field for radium therapy, though in only one out of nine cases of lymphosarcoma—a type of growth known to be very radio-sensitive—was a good result obtained. It has, indeed, been questioned whether irradiation has not increased the tendency to dissemination.

ALL-ENGLISH (PHARMACEUTICAL) MALT EXTRACT.

We have received for publication the following statement by the Ministry of Agriculture and Fisheries:

With the object of improving the market for home produce the Ministry of Agriculture has adopted a policy for the grading and standardization of the agricultural products of this country, and for applying a distinguishing mark as a guarantee of quality and origin to the graded produce. The mark used, known as the National Mark, consists of a small silhouette map of England and Wales, with a circular representation of the Union Jack in the centre, associated with the words "Produce of England and Wales" and "Empire Buying begins at Home."

In accordance with the above policy, the Minister has recently promulgated grades and standards for various kinds of malt products made entire from home-grown grain, and among these the attention of the medical and pharmaceutical professions is particularly invited to the "All-English (Pharmaceutical) Malt Extract" sold either with or without cod-liver oil. Over and above a general provision regarding the purity and soundness of the barley or malt from which this extract is obtained definite standards are laid down for the product in respect of various factors. The specific gravity, for instance, must be not less than 1.4 and the soluble protein content must be at least 5 per cent. of the total weight. A Lintner value of 25 is the prescribed minimum for diastase. When sold in conjunction with cod-liver oil the mixture must contain a definite percentage of oil—namely, 15 per cent. The Pharmacopoeia Commission has been consulted and has concurred in the new standard.

It is admittedly possible for some exception to be taken to the fact that only one standard of All-English (Pharmaceutical) malt extract will be sold under the National Mark, since it is impossible to standardize patients, and medical opinion is not unanimous with regard to the efficacy of certain of the factors concerned. The value of diastase as an aid to digestion, for example, appears in certain cases open to question, but as a general index of vitamin content it is a distinct asset, and its value cannot be ignored. Heat which will kill the diastase will generally also destroy some of the vitamins. The diastatic activity of National Mark Malt Extract may, therefore, be taken as an indication that a proper and suitable process of manufacture has been observed throughout. Experiments show that as a vehicle for carrying accessory food factors, the ordinary malt extracts of commerce have very widely different values. It is hoped, therefore, that the medical profession will appreciate the advantage of having at hand an agent like National Mark (Pharmaceutical) Malt Extract, which can be used with reasonable precision for dealing with the numerous obscure phases of deficiency diseases.

It has been claimed that the protein present in malt extract made from home-grown grain is assimilated to a greater degree, and altogether more easily, than that of imported extracts, or extracts made from imported grain. Whether it is entirely a question of nutritive value, or one of freshness and palatability, there seems to be something in the idea that the product of the clean, sweet, fresh-malted barley from the fields of our own country-side is better in every way than any other for pharmaceutical purposes, and justifies a serious claim for the extended use of National Mark (Pharmaceutical) Malt Extract. It will be placed on the market in the usual way in retail pharmacists' shops in amber glass jars covered with a blue and white seal label bearing the National Mark. It will also be available in wholesale quantities for hospitals and large institutions in containers bearing a similar label.

British Medical Journal.

SATURDAY, DECEMBER 7TH, 1929.

END-RESULTS OF OPERATION FOR GASTRIC AND DUODENAL ULCER.

For many years medicine has suffered the reproach that it is not an exact science. In early times the therapeutic art was wholly empirical; as knowledge accumulated little by little, treatment, though still empirical, came to be based on the observation of a few isolated cases, or on that most untrustworthy guide called "general experience." It is inevitable that the growth of specialism should have given birth to different and often to very conflicting views, for the specialist working at an individual branch of his subject was likely to acquire such exceptional knowledge and technical skill that his results were to be attributed rather to these than to the method he practised; indeed, it has been a common experience that others using the same method, but with less skill, have obtained disappointing results. When, furthermore, two different methods have been practised, the exponents of each have drawn exactly opposite conclusions about their relative value, usually for the reason that they have seen and treated each other's failures, but have had little or no knowledge of each other's successes. The progress of medicine along such divergent lines is shown by the fact that in any branch of practice to-day there is hardly a statement that can be made with no fear of contradiction. With the widespread growth of theoretical knowledge more and more attention has been given to detail and to the collection of statistical data, but the statistics have so commonly been compiled by those who may be regarded as holding a brief for one method of treatment or another that they can hardly fail to represent the results of the individual worker rather than of the method under consideration. The opinion of those responsible for the treatment of the majority of the public, and even public opinion itself, has thus tended to swing from one extreme to the other as it has been influenced by the authoritative statements made first on one side and then on the other.

In no problem of medicine has this conflict of opinion been more evident than in that of the treatment of chronic gastric and duodenal ulcers. Some thirty years ago the majority of these ulcers were treated medically, by rest, by diet, and by the use of bismuth and alkalis. The introduction of surgical measures, however, gave promise of more rapid, safer, and permanent cures, and thus quickly gained a hold upon the public imagination until operation became almost the universal method of treatment. The frequent, and perhaps too frequent, performance of these operations soon showed that they were not free from immediate risk, or from the risk of later dangers and complications. Medical treatment by dieting and the use of bismuth and alkalis has thus been revived and practised with more careful detail. The physician, perhaps forgetting that the patients in whom surgical treatment has been unsuccessful form but a small proportion of the total number of persons who have been operated on, and that they may represent not so much the failure of the method as the failure of those who are but little practised in its use, is inclined to teach that the day of surgery for these lesions is over, and that better results can be got by medical measures. The surgeon, on the other hand, sees the failures of medical treatment; he is influenced by the time that is lost in attempting such measures, by the dangers that arise from haemorrhage and perforation, and more especially by the number of cases of carcinoma that have developed or have been made evident during or after medical treatment. While, therefore, the surgeon produces figures which tend to show that the only safe treatment is by operation, he takes no cognizance of the fact that he has only been able to obtain the results embodied in these figures by years of careful practice, and that his conclusions have thus no general application.

In this chaotic state of professional opinion the British Medical Association has, for the first time in medical history, hit upon the idea of collecting, with a view to their publication, a large number of the end-results of surgical treatment for gastric and duodenal ulcer. The operations were performed by eighty-six surgeons, and the after-histories have for the most part been obtained from general practitioners who have been in intimate touch with their patients, and are entirely unbiased by any enthusiasm for one method or another. They have seen alike the failures of medical and of surgical treatment, and are thus more competent than any specialist to form a just assessment of the relative value of the different methods. The results have been carefully analysed by Dr. A. P. Luff, the Association's honorary director of research, and the figures relating to duodenal and pyloric ulcers are now ready for publication, while the figures for ulcers of the body of the stomach and carcinomata will follow in a month or two's time. The first part of Dr. Luff's report, dealing with duodenal ulcers, is printed at page 1074 this week; the second and third parts, dealing with pyloric ulcers and with perforated duodenal and pyloric ulcers, will appear in our next issue.

The results of the inquiry form a most interesting group of figures, which every consultant and general practitioner should not only read most carefully, but should keep by him for future reference. The most important point, perhaps, which emerges from their perusal is the high percentage of patients who have been able to return to full work; indeed, the figures should show once and for all that the incidence of gastro-jejunal ulcer following gastro-enterostomy is not nearly so high as has frequently been stated. Though it is not safe, perhaps, to assume from a comparison of the different groups that about 10 per cent. of ulcers not treated surgically perforate, yet these figures correspond with those reported by Mr. H. H. Rayner in our present issue at page 1048. His paper is also of interest in showing that in such an untreated group the mortality from haemorrhage is about 20 per cent., whereas in the collective investigation the danger of haemorrhage after operation is shown to be small. Neither Dr. Luff's report nor Mr. Rayner's paper indicates what is the risk of the onset of carcinoma in cases that are not treated surgically, but the carefully compiled figures of Stewart, which show that carcinoma occurs in from 6 to 10 per cent. of all cases of chronic ulcer, are to-day usually accepted, and it is thus of interest to note that in the collective series treated surgically there was no authenticated instance of the late onset of carcinoma.

These collected figures not only show what a great and valuable part the large body of general practitioners may take to-day in medical research; they present statistical conclusions which cannot be regarded merely as the opinion of a specialist in one

or other branch of medicine, but as the considered opinion and conclusions of the medical profession as a whole. It only remains now to collect over an extensive field and publish the end-results of medical treatment, and so to compare the ultimate efficacy of the two methods. The carefully compiled analytical tables of Dr. Luff do not, of course, represent the best results that might be obtained by an individual surgeon, but they establish—if we may be permitted the golfing simile—a "bogey" for the upper abdominal course; a bogey which every physician and surgeon will, by his own methods, endeavour to beat. The more "plus" men we can produce in either team the greater will be the reputation of British medicine and surgery.

CONSTIPATION.

CONSTIPATION is generally regarded as a very common condition, and a belief that it has harmful effects on the whole body is still widespread in the medical profession as well as among the general public. The address by Dr. Geoffrey Evans, printed this week at page 1044, will serve a very useful purpose if it helps to eradicate these mistaken doctrines. The truth is that a large proportion of people who regard themselves as victims of auto-intoxication caused by intestinal stasis are not really constipated at all, but suffering from the effects of treatment, frequently given on their own initiative or on the advice of their friends, but too often prescribed by their medical advisers. As Dr. Evans points out, the *diagnosis* is generally made by the patient himself, who believes that he must be constipated because he is in the habit of taking aperients, and that he is suffering from auto-intoxication because he feels unwell while he is undergoing this regime. If he is persuaded to discontinue all treatment for a few days, and to make an effort to open his bowels after breakfast whether he feels a call to defaecation or not, he *often finds that his bowels* act quite regularly and that his symptoms disappear; he has, in short, been suffering *from the toxaemia* caused by artificially induced diarrhoea.

Dr. Evans emphasizes the fact, upon which the late Sir James Goodhart insisted in his opening address at the discussion on constipation at the Annual Meeting of the British Medical Association in 1910,[1] that the natural state of the colon is to be more or less full, and that attempts to keep it empty by the use of aperients or enemata are based on a misconception of its functions, and can only cause harm. Under normal conditions the ileo-caecal sphincter acts as a barrier which makes it possible for intestinal digestion to be completed before the chyme enters the caecum, just as the pyloric sphincter causes the food to remain for an adequate period in the stomach. In the caecum and ascending colon water is absorbed, and the faeces which are carried by mass peristalsis to the pelvic colon are normally so dry that very little bacterial decomposition can take place within them. Consequently the quantity of toxins produced in the bowels under normal conditions is never more than the liver is able to destroy or to convert into harmless substances which the kidneys can excrete. On the other hand, chyme passes through the small intestine of the habitual pill-taker with such abnormal rapidity that large quantities of incompletely digested food reach the colon, which becomes filled with a semi-fluid material that forms an ideal culture medium for bacteria. In these circumstances toxins are often produced in such great amount that the liver and kidneys are unable to deal with them effectively, and symptoms of intoxication result. Dr. Geoffrey Evans's dictum that "there can be little doubt that almost as much disease and distress of a low-grade and chronic type is caused by the habitual use of laxatives as results from the abuse of alcohol" shows a happy return to sane thinking after the teaching of those who, only ten years ago, were still advocating short-circuiting and colectomy for chronic intestinal stasis, because they held that the harm it caused was "infinitely greater and more far-reaching than that ascribed to alcohol."

It is unfortunate that the stools, which are too often the subject of the most minute examination by the patient, are not inspected by the doctor with greater frequency. The patient should be instructed to "do as the dogs do, and never look behind him," while the medical student should be taught to inspect the stools in intestinal disorders with the same regularity as is expected of him in examining the urine in renal disorders. No man, as Dr. Evans points out, can give a final opinion on the condition of the bowels without seeing the stools, but he should see them under *natural conditions*. An opinion based on the result of an aperient or an intestinal douche is always misleading, as both remove the faeces from the bowel before they are ready to be excreted, and both act as *irritants* to the mucous membrane, which consequently often secretes excess of protective mucus.

The *operative* treatment of constipation is now happily a thing of the past, but in its place a widespread propaganda has developed with the object of altering the habits of the average healthy individual with *regard* to his food and his intestinal activity. Totally indigestible food and unpalatable food substitutes are recommended because they provide an abundant residue to stimulate the bowels to act more frequently, and an attempt has even been made to introduce an "intestinal drill" into schools with the object of teaching children to open their bowels after every meal. Dr. Evans shows how Pavlov's work on the conditioned reflexes should be applied to the normal physiology of the alimentary tract, and he issues a wise warning against attempts to change the bowel habits of the healthy man. Many observers have noted a definite increase in the incidence of chronic gastric and intestinal irritation, which has resulted from the craze for putting excess of "roughage" into the human stomach and bowel, *which are not adapted to deal with it*

When a patient is found to be really suffering from *constipation, and is not simply treating himself* because he thinks he is constipated, it is necessary to distinguish between the result of delay in the passage of faeces through the colon and the equally common *dyschezia*, in which the faeces reach the pelvic colon at the normal rate but defaecation is inefficient. A consideration of the symptoms, together with abdominal and rectal examination, often give sufficient data for an accurate diagnosis. In severe cases an *x*-ray examination is valuable, as it enables the physician to recognize what segments of the colon are involved in colonic constipation or whether dyschezia is present alone or in association with stasis in the proximal parts of the colon. Interpretation of the results of *x*-ray examinations is by no means easy, and it is essential that the radiologist should be familiar with the wide variations which occur in healthy individuals in the position of the colon, in the rate at which the most advanced portion of the opaque meal reaches the pelvic colon, and in the length of *time* required for its last traces to be evacuated from the caecum and

[1] *British Medical Journal*, October 8th, 1910, p. 1038.

ascending colon. Lack of this knowledge may lead to the diagnosis of displacements of the bowel and intestinal stasis when only normal variations from the average are present. It is, in fact, very doubtful whether a pelvic caecum or a low transverse colon is ever a cause of symptoms.

Fortunately, it is possible to cure a large proportion of cases of colonic constipation by diet alone. Sometimes the use of liquid paraffin, as first advocated by Neville Wood in 1906, or of an unirritating vegetable mucilage such as agar-agar, is required, and massage is often of help in severe cases. When the use of aperients cannot be avoided the dose should be so regulated that a single formed stool is produced each morning, and not several soft or semi-liquid stools. Dyschezia can generally be cured by simple psychotherapy in the form of explanation, persuasion, and re-education, but in long-standing cases a course of graduated enemata of glycerin or water may be required.

THE WINNIPEG MEETING.

ARRANGEMENTS are now proceeding apace, both in Canada and in this country, for the ninety-eighth Annual Meeting of the British Medical Association, to be held at Winnipeg next summer, under the presidency of Dr. W. Harvey Smith, professor of ophthalmology in the Manitoba Medical College. The Annual Representative Meeting of 1930 will be held in London at the Association's House, Tavistock Square, from July 18th to 22nd. The Annual Meeting at Winnipeg will open on Tuesday, August 26th, when Professor Arthur Burgess will install his successor in the office of President, and Professor Harvey Smith will give his address to the Association. The scientific and clinical business of the meeting is being organized in thirteen Sections, which will hold their sessions on August 27th, 28th, and 29th. The list of officers of all the Sections is not yet quite complete, but we are now able to publish the names of their presidents, as follows: Medicine, Lord Dawson of Penn; Surgery, Lord Moynihan of Leeds; Obstetrics and Gynaecology, Mr. Comyns Berkeley; Bacteriology, Pathology, Physiology, and Biochemistry, Professor Robert Muir; Diseases of Children, Dr. Robert Hutchison; Mental Diseases and Neurology, Sir E. Farquhar Buzzard, Bt.; Ophthalmology, Mr. Bishop Harman; Laryngology and Otology, Sir StClair Thomson; Preventive Medicine, Dr. A. S. M. Macgregor; Tuberculosis, Professor S. Lyle Cummins; Radiology, Dr. A. E. Barclay; Medical Sociology and History of Medicine, Sir Humphry Rolleston, Bt.; Anaesthesia, Dr. R. E. Apperley. The provisional programme, and further information about the arrangements generally, will be published from time to time in later issues. Members who intend to take part in the Winnipeg meeting should write to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, W.C.1. It is essential that all reservation of cabins on the official steamboats and of accommodation on the special trains should be made through the Head Office. Three tours in Canada have been approved by the Council, and a booklet of information will be sent to any member on request.

SIR WILLIAM BRAGG'S HUXLEY LECTURE.

THE *x*-ray analysis of molecular structure is now a familiar story, but when expounded with the delightful enthusiasm of Sir William Bragg it gains freshness and new interest. It was the main theme of Sir William Bragg's Huxley Lecture, delivered at Charing Cross Hospital Medical School on November 28th, and he spoke of it as one of those borderline subjects appropriate to such an occasion, depending upon physics for the method of investigation, and finding ever more fruitful applications in the chemical and biological sciences in which the organic molecule plays so large a part. Sir William Bragg stressed the point that these new methods of analysis are encouraging in that they form a new science of precision. The trouble lay, he said, not in obtaining the information, but in reading it when obtained. As he expressed it, what the workers in this field are trying to do is not to penetrate some hazy opening in the forest, but, having discovered a map of the region, to interpret and follow it. He described in a fascinating way the persistent tendency of Nature to arrange her molecules in ordered fashion. This arrangement, he said, obtained not merely in the bodies called crystals, but also in wool, hair, and silk, as well as nerve and muscle. In fact, it was difficult to find any material in which, on *x*-ray examination, some geometrical arrangement, repeated at intervals, was not discoverable. The results of this arrangement in some fields—metallurgy, for example—were perfectly familiar, but the tendency to order and repetition was universal, and was the first thing that Nature tried to do when she began to build up her solid bodies. The *x* rays furnished the information, because when they fell upon crystals or other structure reflected rays went off in certain specified directions, and from observing those directions the nature of the arrangement—in diamond, graphite, or whatever it might be—could be elucidated. The *x* rays showed that something—the carbon atom—was repeated perfectly after a certain number of Angstrom units, and perhaps imperfectly repeated after other irregular intervals, and thus the pattern was worked out. Sir William Bragg dwelt upon some recent applications of this work to the structure of cellulose and of wool. Here again Nature built up these long chains, only now they were not merely chains of carbon atoms, but each link was a much more complicated unit. As soon as Nature had built up these long chains she put them together and made bundles of them. The chains themselves were very strong, but the point where one chain joined the next was weaker, and this explained why in certain fabrics there were lines of special weakness and tenuity. The lecture was followed with keen interest by a large gathering, including practically the whole teaching staff and students at Charing Cross.

REPORT OF THE ROYAL COMMISSION ON LOCAL GOVERNMENT.

More than six and a half years ago the Royal Commission on Local Government was appointed, with the Earl of Onslow as its chairman. Its first report was presented in August, 1925. It consisted mainly of a description of the existing system of local government in England and Wales, and of conclusions and recommendations as to the methods of dealing with the constitution and extension of county boroughs. A second report was presented rather more than a year ago. It dealt with five specific questions—the reorganization of areas for local government purposes, the widening of the local area of charge for certain services, measures to stimulate or aid authorities unable or unwilling to perform their functions, the appointment of whole-time medical officers of health, and the better distribution of certain functions. The opinions of the Commission on these questions were required in view of the Local Government Bill, then in an advanced stage of preparation. The third and final report of the Commission was issued last week. This report is in four parts, and the subjects now dealt with fall into three groups. Part I completes the review of the functions of local authorities, so far as this was not set out in the second report, and with the exception of certain matters which have quite recently been investigated by other official bodies—mainly fire brigades, police, and the superannuation of officers—and of the wide and important service of education.

Part II relates to certain issues regarding the constitution and membership of local authorities, and Part III to questions concerning the officers of such authorities. Part IV consists of a summary of the principal conclusions and recommendations. All the matters dealt with in the report are, of course, of some importance—several of them of very great importance—in connexion with local government; but many of them have no particular relationship with public health services, and others are only remotely relevant thereto. There remain, however, a number of points which are directly concerned with public health or with the administration of health services. For instance, among the matters considered in Part I are the administration of the Milk and Dairies Acts, and of the Food and Drugs (Adulteration) Act and the appointment of public analysts, co-operation between local authorities as regards water supplies and the establishment of regional advisory committees, the assimilation of the powers of urban and rural district councils, and the powers of the parish councils in relation to the scavenging of villages. In Part II certain suggestions made by the Ministry of Health in submitting evidence for the creation of a new kind of statutory borough are examined and not approved, and the very important questions of co-option on committees, and of the *disqualification of certain* classes of persons from being members of local authorities, are considered. On both of these questions the British Medical Association has recently made representations to the Ministry of Health, and they are of particular importance to the profession in its relation to public life. In Part III the report, among other matters, deals with the methods of recruitment of the local government service and promotions therein, with security of tenure in that service, with the relationship of the town clerk or clerk to the county council to the other principal officers of an authority, including the medical officer of health, and with what is sometimes an undesirable publicity as regards salaries and promotions. We hope in an early issue of the *Journal* to give a full account of what the report says upon these subjects of direct professional interest, and to make some comments with regard to them. Meanwhile we may congratulate the Royal Commission upon its unusual experience, so contrary to what is traditionally expected, of having had "the singular gratification of seeing many of its recommendations adopted and passed into law" even before the publication of its final report.

THE ETIOLOGY OF "PINK DISEASE."

THE cause of erythredema polyneuritis ("pink disease" of infants) has been variously ascribed to metabolic disturbances resulting from dietetic irregularities, to a pre-existing allergic state, and to infection. In favour of the infection hypothesis are the history of a prodromal naso-pharyngitis with bronchitis, the pyrexia, and the occurrence in some of the cases of ulceration of the tongue and gums. Paterson and Greenfield,[1] moreover, in examining the nervous system of two fatal cases, found evidence of peripheral neuritis and chronic inflammatory changes in the spinal cord and nerve roots. Interest attaches, therefore, to a bacteriological investigation of three cases of "pink disease" carried out in February, 1928, at the South African Institute for Medical Research, and described in the annual report for 1928.[2] The subjects of investigation were patients under the care of Dr. E. P. Baumann at the Children's Hospital, Johannesburg. Cultures were made from their urine, faeces, cerebro-spinal fluid, blood, and nasopharyngeal secretions. The most striking results were derived from the study of capillary blood obtained by puncturing the fingers and toes in the pink hands and feet, culture of this blood yielding in each case a haemolytic *Staphylococcus aureus* and a Gram-positive kidney-shaped diplococcus. The latter organism was also recovered from the urine, faeces, and a mesenteric gland of one patient, and from the tonsils of the other two. Agglutination tests, carried out with immune serum that had been prepared by inoculating rabbits with the diplococcus, appear to have established the fact that the diplococci isolated from the different sources were identical. A monkey that had received a subdural inoculation with the fresh cerebro-spinal fluid from one of the children became emaciated, almost entirely lost the fur over the posterior aspects of its fore and hind limbs, and died in two months. The appearances suggested that the monkey had scratched or rubbed the denuded parts. No far-reaching conclusions have as yet been drawn from the results of this investigation; further cases are being awaited, and will be studied on similar lines. Before the etiological significance of the diplococcus can be determined it will be necessary to discover if its occurrence in cases of "pink disease" is constant, and to obtain further evidence about its antigenic and immunological relation to the disease.

STERILIZATION OF THE UNFIT.

Two books recently issued may be taken as illustrating the kind of propaganda to which the public is now being subjected on the subject of sterilization. They are *Sterilization for Human Betterment*,[1] by E. S. Gosney and Paul Popenoe, and *Sterilization and the Unfit*,[2] by W. M. Gallichan. The former is a relatively temperate and well-informed, but markedly biased, pronouncement, purporting to be "a summary of results of 6,000 operations in California, 1909–1929." The latter is a highly intemperate, even hysterical, harangue, abounding in misleading, if not entirely inaccurate, assertions. The author says: "The alarm now shown by an increasing number of responsible citizens in the United Kingdom lest the unfit may soon vastly outnumber the fit, is almost of the nature of panic." This is a fair sample of the sort of exaggeration in which he too frequently indulges. It does not lead to the production of a dependable book, and it is no service to the really important subjects of eugenics and of sex education that such a farrago of unbalanced statement and wild claims should be issued in their name. For eugenic purposes it is obvious that preferential or selective mating among superior stocks is of the first importance, and that the prevention of propagation among very inferior stocks is of minor value. Nevertheless, the latter may play a considerable part, and a really impartial and strictly scientific inquiry into its exact, though limited, place among eugenic measures, whether by sterilization or segregation, is much to be desired; the time is certainly ripe for such an inquiry in the case of mental deficiency. The more important book by Drs. Gosney and Popenoe does not embody the results of an impartial inquiry. Its bias is manifest and avowed. As an example of the way in which this bias works we may give the following quotations. Speaking of the conduct of feeble-minded persons on parole, when sterilization is being advocated it is said: "One in every twelve of the females paroled after sterilization becomes a sex offender, but nine out of twelve were sex offenders before commitment to the institution. This improvement is not wholly due to the effect of sterilization, but is doubtless attributable in part to the training they received in the State institution, and to the fact that they know they are on parole and will be returned to the institution if they do not behave themselves." When the

[1] *Sterilization for Human Betterment.* By E. S. Gosney, B.S., LL.B., and Paul Popenoe, D.Sc. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1929. (Cr. 8vo, pp. xviii + 202. 8s. 6d. net.)

[2] *The Sterilization of the Unfit.* By Walter M. Gallichan. London: T. Werner Laurie, Ltd. 1929. (5 × 7¾, pp. 192. 7s. 6d.)

procedure by castration is being deprecated, they say: "A number of castrations in Switzerland have been described, and it has been alleged that as a result a patient who had formerly been unable to live in the community was enabled to go back to a normal social life. . . . But it has not been shown that this effect was due merely to the castration, and not to the other treatment given at the hospital. Many patients with similar difficulties who are not castrated, but merely given the customary hospital treatment, also recover and can be returned to the community." A similar manipulation of argument appears frequently in the volume, and a similar tendency to draw deductions of a far-reaching character from one, or two, or a few cases. Nevertheless, careful perusal leads to the conclusion that the authors are anxious to keep their claims for the value of sterilization within moderate bounds. Whereas Mr. Gallichan asserts that vasectomy will improve the mental and physical well-being of all who will submit to it, Drs. Gosney and Popenoe modestly assert that it does no harm. Whereas the former believes that "mental deficiency may be banished after a few years of sterilization," the latter are content to claim that "the number of mentally defective persons in the community could be reduced by perhaps as much as half in three or four generations." It is this latter more moderate claim that requires further careful examination; many of those with scientific knowledge of the subject regard even this claim as much too high. No one disputes that in the case of a number of individuals or of families sterilization may be an effective preventive measure; but as a measure calculated to produce any widespread social or eugenic betterment it is almost beyond dispute that sterilization would have to be systematically applied to a proportion of the whole population approximating to one-tenth. It appears that the expectation even of Drs. Gosney and Popenoe is based on the condition that "the mental defectives in the public school system" shall be dealt with, "subsequently also canvassing their relatives for additional cases." All such wide compulsory measures are beyond practical possibility even if they were otherwise desirable. As a measure which might result in the safe return to the community of a somewhat larger number of defectives than would otherwise be possible, sterilization merits further investigation; but this is a very limited result to look for, since defectives whose conduct was definitely antisocial would have to be retained in the institution in any case, and those whose conduct was relatively decent might be expected, even without sterilization, to fulfil some useful function in the community of which they were members without being more dangerous to the race than other folk. One interesting result does seem to emerge from the Californian experience. A common theoretical objection to sterilization is that the sterilized moron would be more likely, and not less likely, to indulge in promiscuous sexual intercourse, and thus perpetuate or increase certain evils. It appears, however, that in the cases investigated this has not occurred; but the actual truth in such an investigation must be very difficult to elicit, and the number of cases inquired into was relatively few.

STATUS OF THE SCHOOL MEDICAL OFFICER.

In the report for 1928 of the Chief Medical Officer of the Board of Education there appear certain observations on the organization of the school medical service which have an important bearing on the status of the school medical officer. It is well known that in certain areas attempts have been made to bring this officer's work under the control of the local director of education, and to deny him direct access to the local and central educational authorities. While it is true that the director of education is the person best fitted to co-ordinate the work undertaken by the educational authority, it would be a pity if too generous an interpretation of his duties were allowed to prejudice the work of the school medical officer. The purpose of the medical inspection and treatment of school children is to make them fit to receive the education provided by the State, and its fulfilment demands, indeed, that the school medical service should be organized as an integral part of the educational system of the country, to be paid for out of the education rate, and carried out on school premises, in school hours, with the necessary assistance of school officers, and in association with the school curriculum. At the same time, however, the school medical service, as Sir George Newman points out, is part of the public health service of the country, and should not be divorced from it. Indeed, in 1907-8 the Board of Education recommended that the school medical officer, though appointed by the local education authority, and receiving instructions directly from the Board and the authority, should be closely associated with the medical officer of health of the area; that he should report directly and independently to the authority; and that his report be submitted to the Board. In other words, it held that the work of medical inspection should be carried out in intimate conjunction with the public health authorities and by or under the direct supervision of the medical officer of health. "School hygiene," writes Sir George Newman, "cannot be divorced from home hygiene, and this in turn is intimately bound up with the hygienic conditions of the community. Efficiency and economy require, therefore, an organic relationship between the daily work of the school authority and of the authority responsible for the administration of the wider branches of public health." This appears to us to be an admirable and a just statement of the position. What is involved is not simply the dignity of the school medical officer, but the efficiency of the service for which he is in large part responsible; his recommendations cannot but lose in effectiveness if they have to be transmitted to the authority indirectly through a lay person. Such circumlocution has been known, moreover, to permit the loss of important observations; direct communication, on the other hand—with the corollary that the communication must also go to the Board of Education—provides the best assurance against omission or neglect.

THE ROAD TRAFFIC BILL.

To the medical profession the most interesting provisions of the Road Traffic Bill are those which seek to impose on all applicants for licences to drive motor vehicles standards of physical fitness to which they must conform. Driving by young persons is restricted in clauses which provide that no one under 16 shall drive a motor vehicle on the road, the minimum age limits for drivers of motor cycles, ordinary motor vehicles, and heavy vehicles being respectively 16, 17, and 21, subject to the right of persons already holding licences to renew them. On the form of application for a licence the applicant will have to declare his age, notify the licensing authority about the existence of any conviction or order of the court disqualifying him from holding or obtaining a licence, and state whether or not he is suffering from "any such disease or physical disability as may be specified in the form, or any other disease or physical disability which would be likely to cause the driving by him of a motor vehicle, being a vehicle of such a class or description as he would be authorized by the licence to drive, to be a source of danger to the public." If from this declaration it appears that the applicant is suffering from any such disease or disability, the licensing authority will, except in special circumstances provided for in the bill, refuse to grant a licence. The saving clauses include the right of certain applicants to submit themselves to tests of fitness and ability to drive. In order to protect the public from risks caused by excessive fatigue on the part of the drivers,

provision is made to limit the continuous period of duty of persons engaged in driving public service conveyances, or any motor vehicles constructed to carry goods other than the effects of passengers, to five hours, and to not more than ten hours in the aggregate in any consecutive twenty-four hours. For the purpose of this provision any two or more periods of time will be regarded as continuous unless they are separated by an interval of not less than half an hour, during which the driver is not engaged on any work whatever in connexion with the vehicle. The bill proposes to divide England and Wales into ten, and Scotland into two, traffic areas, and for each area the Minister of Transport will appoint three commissioners, who apparently will be the sole authorities in their areas for licensing public service vehicles. The framing of regulations with regard to the physical fitness of public service drivers is thus left—subject to regulations that the Minister of Transport may make in this connexion—to the local commissioners, and there is some risk that while these may define standards no less rigorous than those already enforced on their employees by such public transport companies as the L.G.O.C., they may tolerate the lax standard now prevailing among some of the other transport companies. We are glad to note that in the clause of the bill relating to the effect on drivers of drink and drugs, the expression "drunk" is not adopted, but, as was suggested in the British Medical Association's report on tests for drunkenness, "under the influence of drink." The penalties for driving while under the influence of drink or drugs are heavy—namely, imprisonment for a period not exceeding four months, or a fine not exceeding £50, or both imprisonment and fine. We can find no indication in the bill of the diseases or disabilities which are to debar an applicant from obtaining a licence, or what tests for physical fitness will be imposed. The British Medical Association's special committee which is dealing with the question of tests for drivers of motor vehicles will take an early opportunity of examining the proposals in the bill.

AUSTRALIAN SNAKE VENOMS.

An important investigation on Australian snake venoms, inaugurated by Dr. N. A. Fairley, and conducted by him and Dr. C. H. Kellaway on behalf of the Department of Health of the Commonwealth Government, is described in some detail in the report for 1928-29 of the Walter and Eliza Hall Institute of Research in Pathology and Medicine, in the laboratories of which institute the investigation was carried out. According to Dr. Cumpston, there have been 244 deaths from snake bite in the Commonwealth during the last seventeen years, the mortality rates being 50 per cent. from death adder bites, 40 per cent. from tiger snake bites, and 8.6 per cent. from brown snake bites (Tidswell and Ferguson). The relative danger of the various snakes to man depends not only on the amount of toxicity of the venom available in each, but on the efficiency of the biting mechanism of the snakes and on their ferocity. When confronted most Australian snakes, fortunately, are more anxious to get away than to fight. Dr. Fairley emphasizes the extreme shortness of the period which elapses between the bite and the diffusion of a lethal dose of venom into the circulation, the absorption time in sheep bitten by a tiger snake being less than two minutes. It is necessary, therefore, within this time to apply a ligature tightly enough to obstruct the circulation completely, and to excise the bite without delay. Ligature itself, apart from its immediate effect of preventing absorption while excision is being rapidly performed, has no therapeutic value. Sir Charles Martin has shown that, although in the rabbit six to ten times the fatal dose of black snake venom can safely be injected into a limb the circulation of which is completely blocked for twenty minutes, the method depends for its efficacy on a thermolabile substance present in the venom. If the "thrombase" in the venom is destroyed by heating it to 75° C. ligature can do no more than delay the time of death. Similarly, in sheep inoculated with death adder and copperhead venoms, from both of which thrombase was shown to be absent, the effect of ligature was to prolong but not save life. For the treatment of snake bite Fairley advocates excision of an area of skin and the subcutaneous tissue surrounding the bite measuring 3.2 by 1.9 centimetres, with the longer diameter through the line joining the fang punctures. In bites of the hand and foot dissection should be continued down to the bone, and in other regions it should be deeper than the length of the fangs—5 or 6 mm. The wound may be swabbed with a 5 per cent. permanganate solution and an Esmarch bandage applied from the ligature downward; the ligature should be left in position for at least twenty to thirty minutes after excision. Dr. Kellaway is at present investigating active immunization against snake venoms and the nature and toxicity of the venoms of some of the rarer snakes.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF CANADA.

On June 14th last an Act to incorporate a Royal College of Physicians and Surgeons of Canada received the Royal assent, and in accordance therewith an inaugural meeting, convened by the general secretary of the Canadian Medical Association, was held at Ottawa on November 20th. This meeting was attended by sixty of the leaders of the medical profession in Canada, designated Charter Fellows, and it marked the culmination of a movement which began in 1920. The Act provides that the council may organize the College into medical and surgical divisions, those admitted into them being designated Fellows of the Royal College of Physicians of Canada or Fellows of the Royal College of Surgeons of Canada (or their equivalents in the French language). At the inaugural meeting Toronto was chosen as the headquarters of the College; Professor Jonathan C. Meakins of McGill University, Montreal, was elected president; Professor Duncan Graham of Toronto vice-president in charge of the medical division; and Dr. F. N. G. Starr, also of Toronto, vice-president in charge of the surgical division. Dr. T. C. Routley, general secretary of the Canadian Medical Association, was elected registrar-secretary. It is hoped that the new College may prove of great service to the profession in Canada by bringing together as a corporate body all physicians and surgeons of high standing in the Dominion, and that through the issue of higher diplomas it will deter medical men from becoming specialists without special training.

THE PART-TIME SANATORIUM.

An interesting experiment in the prophylaxis and early treatment of tuberculosis is reported from Russia.[1] A number of so-called "night sanatoriums" have been opened in Moscow for the observation and treatment of factory workers suspected by the public health authorities of incipient tuberculosis; the patients continue at work while undergoing treatment. When the factory closes at 4 p.m. the patient goes to the sanatorium, where a warm bath is followed by a meal at 6 p.m., half an hour's walk in the garden, and an hour's rest. At 9 o'clock the patients are served with tea, milk, and bread, and are obliged to be in bed an hour later. They are given a substantial breakfast before starting for work in the morning, and take a light meal with them. The diet is so arranged that each patient receives 4,000 to 5,000 calories daily. On three evenings a week light physical drill or other non-strenuous exercise is organized, and twice a week the patients are examined by the medical officer in charge. Ordinarily the treatment lasts eight or nine weeks.

A MEMORIAL TO WILLIAM HARVEY.

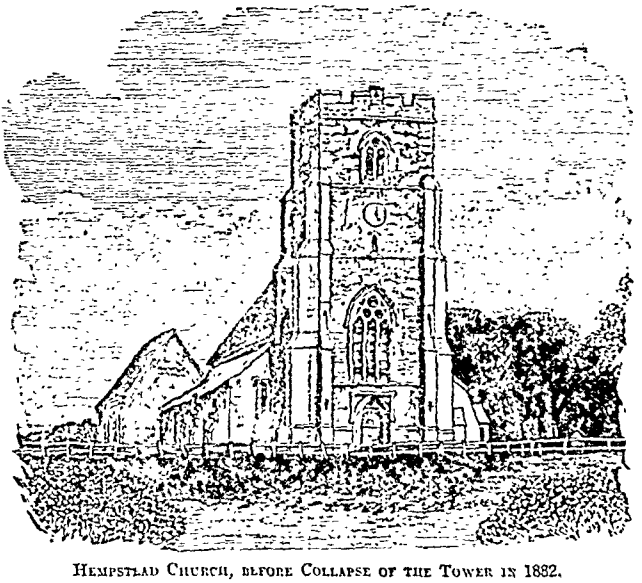
REBUILDING THE TOWER OF HEMPSTEAD CHURCH.

SOME years ago a committee was formed to carry out the rebuilding of the tower of Hempstead Church as a Harvey memorial, and some £1,000 was raised, in part locally and in part from the medical profession. Recently the committee has been reconstituted, and an appeal in the following terms is about to be issued to the medical profession:

The mortal remains of William Harvey, the great exponent of the experimental method in biology and the founder of scientific medicine, lie in a sarcophagus in Hempstead Church, Essex, to which they were transferred in the year 1883 from the Harvey vault beneath the church at the cost of the Royal College of Physicians of London. Hempstead Church, a fourteenth century church of very considerable interest, was closely linked with the Harveys, and contains several memorials to other members of this family who achieved distinction in many branches of human activity.

This church must always make a very special appeal to all connected with the profession of medicine, since it is the place of burial of one who rendered not only in his own time, but for all time, the greatest service to medicine, by establishing it on a secure foundation, and also by inculcating the method by which its progress and development could best be furthered.

On January 28th, 1882, the tower of this ancient church collapsed, and the heap of ruins remains in the churchyard to this day, imparting to the surroundings an air of desolation that must be seen to be appreciated.



HEMPSTEAD CHURCH, BEFORE COLLAPSE OF THE TOWER IN 1882.

Upwards of £1,000 has been collected towards the £5,700 required to meet the estimated cost of rebuilding the tower with the old materials. This appeal is addressed to the medical profession of the British Empire, in the hope that the sum required to restore the tower may be obtained with as little delay as possible, and so enable a suitable memorial to be raised to the memory of Harvey by those best qualified to appreciate the greatness of his achievement and the service he rendered to humanity.

The chairman of the Harvey Memorial Committee is Sir John Rose Bradford, President of the Royal College of Physicians of London; the vice-chairman is Lord Stamfordham, treasurer of St. Bartholomew's Hospital; and among its members are the Regius Professors of Medicine at Oxford and Cambridge, the Master of Caius, and the Warden of Merton, Sir Thomas Barlow, Sir Charles Sherrington, Sir D'Arcy Power, Sir William Hale-White, and Dr. Herbert Spencer. Donations should be made payable to the Harvey Memorial Fund, and may be sent to the honorary treasurer, Mr. A. W. Ruggles-Brise (Spains Hall, Braintree), or to Dr. Arnold Stott (58, Harley Street, W.1), who is acting as joint honorary secretary with the Vicar of Hempstead.

A detailed account of the Harvey Chapel, on the north side of the chancel, was written by Sir Dawson Williams, the late Editor of this *Journal*, shortly before his death, and appeared in our issue of May 12th, 1928 (p. 816).

Our first illustration, from an old woodcut, shows the church and its massive tower before 1882; the other two illustrations show the "towerless nave," from the west and south, as it stands to-day.

HARVEY'S RUINED BURIAL PLACE.

BY

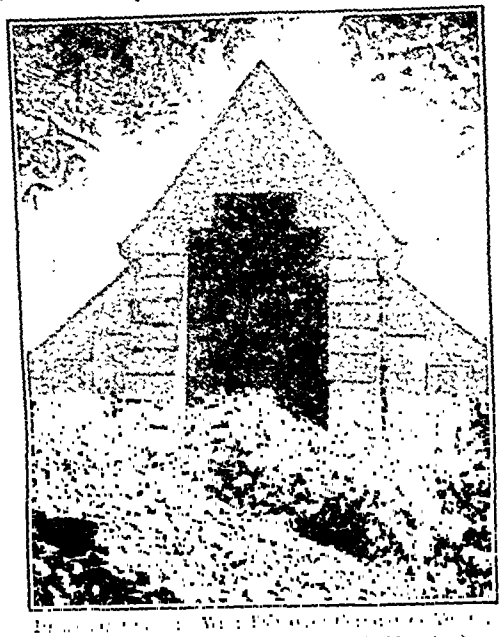
MICHAEL GRABHAM, M.D., LL.D.,
Fellow of the Royal College of Physicians.

HEMPSTEAD lies in a sparsely peopled district of Essex, seven miles from any important town, and equally remote from railway communication. The parish church, a really fine structure showing pure Early English work, is probably 500 years old, and is built of hard chalky stone on one of those gravels which in the country are regarded as unstable and shifting if the stratum has the slightest tilt. Hence, or from some such cause, the massive tower of Hempstead Church, with its clock and fine peal of bells, collapsed forty-seven years ago, broken from its very foundation, though the body of the church has not greatly suffered.

Now the interest of this church concerns all of us, and is twofold. Our first consideration is both medical and world-wide, for the body of William Harvey, who discovered the meaning of cardiac movements and the circulation of the blood and thus redirected the current of medical thought, is enshrined here in our custodianship for the human race; while secondly, the mortal remains of the celebrated Admiral Sir Eliab Harvey, in the kindred of our medical genius and one of Nelson's Trafalgar captains, are here preserved in the huge vault of the Harvey family. It is difficult to estimate the services of this intrepid officer in the crisis of the Trafalgar victory, for with one side of his vessel torn asunder he managed to get his remaining intact broadside to bear upon a fresh enemy ship "black with boarders," with annihilating effect. With perfect restraint and discipline he thus appears, by one single discharge, to have added a first-rate prize to the long list of Trafalgar captures. In early life, sixty-five years ago, I gathered much of the exploit I have related from conversation with Lady Bouchier and Admiral Codrington, children of one of Nelson's Trafalgar captains.

These two, then—our own William Harvey and Captain Harvey of Trafalgar—are our special concern, and the concern of the Empire, in the preservation of this Essex church. I have no shadow of authority to speak for the College of Physicians where responsibility for Hempstead has been assumed; but as senior Fellow—save one—I am confident of the indulgence of my colleagues when I venture to suggest that the co-operation of the British Medical Association is essential for the success of this rebuilding

project. We are all members of this great Association; our influence is penetrating and all-pervading; everyone



(From a photograph by Mr. F. D. Hunt, Walthamstow.)

in the Empire is a patient of one of us and easily accessible, and it should be a privilege to all to help us. It should be quite easy, with our perfect organization, to make provision for the rebuilding of a church tower which touches us so vitally. Let us, with all haste and reverence, efface a

WEST END OF NAVE AND SOUTH PORCH.

(From a photograph by Mr. George Walter Grabham, O.B.E., M.A.)

reproach obvious both medically and nationally in the ruins of this Essex church. The Trafalgar signal is still flying—England expects every man to do his duty.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

MEETING OF THE COURT OF GOVERNORS.

THE first meeting of the Court of Governors of the London School of Hygiene and Tropical Medicine to be held in its new home at Bloomsbury took place on November 27th, with Sir HOLBURT WARING in the chair. It will be remembered that the building was opened by the Prince of Wales in July last.

Dr. ANDREW BALFOUR, the director, gave an account of the work of the school during a year of great activity. As to the building, he said that some work still remained to be done; in particular, the large-scale biochemistry plant, the constant temperature room, the central photographic section, and that portion of the museum devoted to sanitary engineering and public health propaganda would not be wholly completed until a somewhat later date. With regard to the teaching, a scheme of study in public health, framed on different lines from any course hitherto in vogue, came into operation in October. Its chief feature was an attempt to co-ordinate the different branches of study in such a way that one dovetailed into another, and the whole formed a combined and logical exposition of the subject. Dr. Balfour illustrated by means of an elaborately coloured chart how the course was organized. Arrangements had been made for students to receive instruction in public health administration in the metropolitan borough of St. Marylebone and the urban district of Willesden, while the health departments of the London County Council, the City of London, and the Port of London had indicated their readiness to co-operate in the teaching work of the school. The medical officers of health for St. Marylebone and Willesden (Dr. Charles Porter and Dr. G. F. Buchan) were serving as lecturers on public health administration and practice, and a panel of visiting lecturers, experts in various branches of public health work, had been nominated for a period of one year to assist the director of the division (Professor Jameson) in D.P.H. teaching. Certain alterations had also been made in the general course in tropical medicine and hygiene, the new course occupying twenty instead of seventeen weeks' instruction. In discussing the detailed work in the divisions and departments, Dr. Balfour mentioned that Professor Jameson had paid a most fruitful visit to the United States, studying methods of public health teaching and practice in the principal schools of hygiene and some of the health departments of North America. He also spoke of the work overseas of the three officers holding appointments as lecturers or Milner Fellows in the departments of entomology, helminthology, and protozoology; of the success of the advanced courses in bacteriology and in epidemiology and vital statistics; of the developments in the library and museum; and of the progress made with research work, in which one group of subjects is financed mainly from the capital and interest of the Milner Research Fund, and the other—under the Institute of Agricultural Parasitology—from Exchequer grants received through the Ministry of Agriculture.

Sir HOLBURT WARING, as treasurer, reported that at the end of the academic year there was a slight excess of income over expenditure. With regard to the capital account, on the site, building, and equipment there had been spent, up to the end of the financial year, approximately £400,000, and there remained a little over £100,000 still to pay. With regard to the future, the University Grants Committee had intimated that the Treasury had sanctioned a recurrent grant in aid at the rate of £40,000 a year, but had impressed upon the school the necessity for taking all possible steps to secure an increased private income from the Colonies, from private or public subscriptions, and in other ways. General satisfaction had been expressed with regard to the new building, and especially with the lecture hall.

Sir W. ARTHUR ROBINSON proposed a vote of thanks to Sir Holburt Waring and Dr. Balfour for their reports. The governors all felt that the school had made an excellent start in its new home. Sir HARRY GOSCHEN seconded the vote.

The CHAIRMAN stated that the new Court of Governors, the members of which are appointed by about twenty-six official departments, university authorities, and voluntary associations, would be substantially the same as the old, except that the governors appointed by the General Medical Council would drop out. In view of its peculiar position in relation to the medical schools, the General Medical Council, while it had assisted in the recent developments, felt it inexpedient to continue permanently to appoint governors.

Collective Investigation into THE AFTER-HISTORY OF GASTRO-ENTEROSTOMY.

Report by

ARTHUR P. LUFF, C.B.E., M.D., B.Sc., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL; HONORARY DIRECTOR OF THE RESEARCH.

THE British Medical Association, in connexion with its collective investigation scheme, decided in 1928 to conduct an inquiry into the after-history of gastro-enterostomy in respect of cases operated on during the period 1920-24 inclusive, and for that purpose two forms dealing with the questions to be answered were issued to those members of the Association who were willing to take part in the inquiry. One form dealt in Section A with sex, age, occupation, and the operative and immediate post-operative history, and in Section B with the after-history when hospital treatment had ceased. The other form requested an indication of the views of surgeons and medical practitioners as to the value of the operation. Considerable care has been taken by a large number of surgeons and medical practitioners in the filling up of these forms, and valuable information has been obtained as to the results of the operation. Acknowledgement must be especially made of the praiseworthy response of so large a number of medical practitioners to the request for particulars of the after-histories of cases, and to the conscientious manner in which they have discharged what must have been a very onerous task. Any utility that may result from this investigation will be mainly due to their generous efforts.

Reports of 2,609 cases have been received in response to this inquiry. The conditions dealt with and the number of reports on each were as follows:

	No. of Reports.
Cases of duodenal ulcer	995
" perforated duodenal ulcer	112
" pyloric ulcer	451
" perforated pyloric ulcer	20
" gastric ulcer	603
" perforated gastric ulcer	42
" growths	336

There were in addition 47 reports which were inadequately filled in, and had to be rejected as useless for the purposes of the inquiry.

These returns represent the operative work of eighty-six surgeons, and may therefore be taken as a fair indication of the value of the operation as performed by a number of surgeons, all of whom were attached to hospitals containing not less than a hundred beds.

Owing to the large number of cases returned and the mass of details that had to be dealt with, it is proposed in this part of the report to deal only with the cases of duodenal ulcers, and to issue subsequent reports on the cases of pyloric ulcers, gastric ulcers, perforated ulcers, and growths.

PART I.—DUODENAL ULCERS.

There were 995 reports of the results of operations for duodenal ulcer; they do not include the perforated cases, which will be dealt with in a subsequent report. The answers to the various questions have been carefully collated, and the results are embodied in the following tables.

TABLE I.—*Sex Incidence.*

Number of cases	995
Males (percentage)	83.6
Females (percentage)	16.4

This table shows that about five times as many cases occur among males as among females.

TABLE II.—*Age Incidence (at Time of Operation).*

Age.	Percentage.
11–20 years	15.9
21–30 "	29.1
31–40 "	31.4
41–50 "	13.1
51–60 "	5.5
61–70 "	

This table shows that the majority of patients with duodenal ulcer were operated on between 30 and 50 years of age. Of the patients operated on between 14 and 30 years one only was 14 years of age, and two were 17 years of age.

TABLE III.—*Type of Operation.*

Type of Operation.	No. of Cases.	Percentage.
Posterior gastro-enterostomy	785	79.0
Posterior gastro-entero-tomy and cuddling of ulcer	129	15.0
Anterior gastro-enterostomy	13	1.3
Gastro-duodenostomy	9	
Posterior gastro-enterostomy and excision of ulcers	8	
Anterior gastro-enterostomy and lateral anastomosis	6	3.2
Posterior gastro-enterostomy and lateral anastomosis	5	
Gastro-enterostomy and partial gastrectomy	2	
Posterior gastro-enterostomy and enterotomy	1	
Excision of ulcer only	1	

In addition, appendicectomy was performed in 29.6 per cent., and cholecystotomy in 2.1 per cent. of the cases.

The reasons for operating were given in 787 cases. They are recorded in the following table.

TABLE IV.—*Reasons for Operating.*

Symptoms.	No. of Cases.	Percentage.
Pain	787	100.0
Vomiting	326	41.4
Melaena	85	10.8
Haematemesis	64	8.1
Haemat. mesis and melaena	27	3.4
Loss of weight	35	4.5

With regard to haemorrhage as one of the reasons for operating, it will be seen from the above table that all the cases in which melaena and haematemesis occurred (separately or combined) only total 22.3 per cent., but amongst the 787 cases very few systematic investigations for occult blood are recorded.

The direct results of operation in the 995 cases were as follows.

TABLE V.—*Results of Operation.*

Result	No. of Cases	Percentage.
Good recovery	910	91.5
Delayed recovery	35	3.5
Death	50	5.0

The results in 492 cases submitted to x-ray examination prior to operation are shown in the following table.

TABLE VI.—*Results of X-Ray Examinations.*

Result.	Percentage.
Positive	65.6
Negative	17.3
Pyloric obstruction only shown	17.1

In 123 cases test meals were employed prior to operation. The results are recorded in Table VII.

TABLE VII.—*Results of Test Meals.*

Result.	Percentage.
Hyperchlorhydria	66.2
Normal acidity	9.7
No free hydrochloric acid	4.1

AFTER-HISTORIES OF THE OPERATION CASES.

The 995 cases dealt with in Tables I, II, III, and V include 744 cases in which the after-histories were given, 19 cases in which the after-histories consisted only of statements that the patients were in good health at some specified time after operation, and 232 cases in which no after-history was given. For the preparation of the after-history statistics the 744 cases only are employed. In the majority of these cases the questions relating to the after-history were all answered, but as in a few cases some of the questions were left unanswered, the statistics in the following tables have been worked out as percentages of the numbers of the answers to the respective questions.

The after-history inquiries were directed to the elucidation of the following points. Pain or other discomfort after food; diarrhœa or constipation; ability to take food; time of return to work after operation; full work or not; gain or loss of weight; condition of health and well-being after operation; any medical treatment found necessary.

TABLE VIII.—*Pain or Other Discomfort After Food.*
(Information on these points was given in 671 cases.)

	No. of Cases.	Percentage.
No pain or discomfort	447	66.6
Occasional slight pain or discomfort	99	14.8
Temporary pain or discomfort (in most cases soon after operation)	84	12.5
Severe pain or discomfort	41	6.1

TABLE IX.—*Diarrhœa.*
(Diarrhœa occurred in 45 cases out of the 741.)

Diarrhœa.	No. of Cases.	Percentage.
Slight	41	5.5
Severe	4	0.5

TABLE X.—*Constipation.*
(Constipation occurred in 126 cases out of the 741.)

Constipation.	No. of Cases.	Percentage.
Slight	111	14.9
Severe	15	2.0

TABLE XI.—*Food Able to be Taken.*
(Information as to diet was given in all of the 744 cases.)

	No. of Cases	Percentage
Full diet	462	62.1
Certain articles of diet avoided	282	37.9

In the majority of the 282 cases in which some modification of the diet was necessary only one or two articles of diet had to be avoided on account of their producing flatulence or indigestion. Among these cases 161 avoided some form or forms of protein food (beef, mutton, veal, pork, bacon, cheese, eggs), and 121 avoided some form or forms of carbohydrate food (vegetables, pastry, fats, fruit). Therefore, of those on a modified diet about 60 per cent. were obliged to avoid some form of protein, and 40 per cent. some form of carbohydrate. These results are opposed to the view expressed by L. B. Broster,[1] who states that in a general way pastry and carbohydrates upset the duodenal ulcers.

Information as to the time of return to work after operation was given in 580 cases. In a certain number of other cases it was stated that the individuals were either of the leisured classes doing no work, or were past the age for work. The particulars are given in the following table.

TABLE XII.—*Time of Return to Work After Operation.*

Time of Return to Work.	No. of Cases.	Percentage.
1 to 2 months	171	30.0
2 to 3 ,,	250	43.1
3 to 4 ,,	61	11.7
4 to 6 ,,	54	9.3
Over 6 ,,	34	5.9

This table shows that 73.1 per cent. returned to work within three months from the date of the operation. With regard to those that did not return to work till after three months, the reasons given in the majority of the cases were that there was no immediate necessity for return, or that work was not available at the time.

TABLE XIII.—*Work Capacity.*
(Information on this point was given in 602 cases.)

Work Capacity.	No. of Cases.	Percentage.
Full work	555	91.0
Light work	34	5.7
Unable to work	2	0.3

TABLE XIV.—*Weight After Operation.*
(Information on this point was given in 637 cases.)

Weight.	No. of Cases.	Percentage.
Gained	458	71.9
Constant	140	22.0
Lost	39	6.1

TABLE XV.—*Condition of Health and Well-being After Operation.*
(Information on this point was given in 620 cases.)

Health.	No. of Cases.	Percentage
General improvement of health	572	92.2
Fair improvement of health	32	5.2
No improvement of health	16	2.6

Subsequent Medical Treatment Required.

Among the 744 cases subsequent medical treatment was necessary in 34—that is, 4.5 per cent. of the cases. Among these, laxatives were required in 13 cases, occasional alkaline treatment in 10 cases, occasional bismuth and sodium bicarbonate for flatulence in 7 cases, bismuth and pepsin in 3 cases, and astringents for persistent diarrhœa in 1 case.

TABLE XVI.—*Number of Years After Operation during which Patients were under Observation, or during which Reliable Information was Obtained.*
(Definite information on this point was given in 657 cases.)

Years under Observation.	No. of Cases.	Percentage.
2–3 years	10	1.5
3–4 ,,	100	15.2
4–5 ,,	181	27.5
5–6 ,,	148	22.6
6–7 ,,	108	16.4
7–8 ,,	76	11.6
8–9 ,,	34	5.2

This table shows that 83 per cent. of the patients were under reliable observation for periods ranging from four to nine years.

Classification of Results.

The classification adopted is somewhat similar to that of L. R. Broster.[2] The cases are grouped according to results in the following manner.

Very good. Able to eat anything; no pain; gained or constant weight; in full work; occasional slight flatulence in a few cases.

Good. Improved; no pain or only occasional pain from indiscretion in diet; gained or constant weight; work; able to eat all foods except one or two items.

Fair. Restricted diet; light work; pain requiring medical treatment.

Poor Operation of little or no benefit; able to do little or no work.

TABLE XVII.—*Classification of Results.*
(The results returned enabled this classification to be made in 669 cases.)

Classification.	No. of Cases.	Percentage.
Very good	450	67.2
Good	149	22.3
Fair	34	5.1
Poor	36	5.4

From this table it will be seen that the late results of the operation were very satisfactory in 89.5 per cent. of the cases.

Occupation.

As the occupational incidence of duodenal and pyloric ulcers was practically the same it has been considered advisable to include both types of ulcer in this section. It will therefore not be necessary to refer to occupation when dealing with pyloric ulcers in a subsequent report. The occupations were given in 1,389 cases of duodenal and pyloric ulcers, including the cases of perforation, and have been classified as follows.

TABLE XVIII.—*Occupational Incidence.*

Occupation.	No. of Cases.	Percentage.
Mechanics and skilled artisans	306	22
Labourers	209	15
Domestic workers	213	15
Professional and leisured classes	129	9
Factory workers	118	9
Shop workers	123	9
Clerks	90	6
Farmers and land workers	56	4
Miners	50	4
Various occupations	95	7

It will be seen that duodenal and pyloric ulcers occur amongst individuals engaged in all kinds of occupations, but rather more than half of the cases occur amongst those whose occupations suggest the consumption of one or more meals a day under uncomfortable conditions, and possibly in a hurried manner, with consequent probable interference with normal digestion. This is even more marked in the cases of perforated ulcers, as 76 per cent. of these occur among those engaged in such occupations. The great majority of the returns received in this investigation are of hospital patients, so that the above figures give no indication as to the occurrence of the disease among the bulk of the middle and upper classes.

Secondary Gastro-jejunal Ulcers.

Number.—Twenty-one ulcers of this type—that is, 2.8 per cent.—occurred among the 744 cases in which after-histories were given.

Sex.—All males.

Age.—80 per cent. of the cases occurred between 30 and 50 years of age.

Symptoms.—Pain occurred in 13 cases, haemorrhage in 7, and vomiting in 4.

The 2.8 per cent. incidence of these ulcers, and the fact that they all occurred among males, confirm the statement of A. J. Walton[3] that the incidence of gastro-jejunal ulceration for duodenal ulcers is about 3 per cent., and that practically it is only found in the male sex. Moynihan[4] states that the records of his cases over a period of twelve years gave 1.84 per cent. of cases that developed gastro-jejunal ulceration.

TABLE XIX.—*Periods After the Gastro-enterostomy Operation at which Symptoms occurred necessitating Operation for Gastro-jejunal Ulceration.*

Period.	No. of Cases.
15 days	1
6 weeks	1
6–12 months	4
1–2 years	2
2–3 ,,	4
3–4 ,,	5
4–6 ,,	4

It will be seen from this table that 38 per cent. of the gastro-jejunal ulcers occurred within two years of the operation, and 62 per cent. between two and six years after the operation. Moynihan[5] states that as a rule this form of ulcer, if it comes at all, comes within two years of the operation.

Sites of the Gastro-jejunal Ulcers.—These were mentioned in four cases only: one at the pyloric antrum; one at the distal side of the gastro-enterostomy stoma; one adherent to the middle colic artery; one half an inch distal to the gastro-enterostomy.

Results of Operations for the Gastro-jejunal Ulcers.—Good recovery in 13 cases; death in 7 cases; one patient too weak for operation.

Synopsis of Operations Performed.

Partial gastrectomy. Four cases—all recovered.

Ulcer excised. Two cases—one recovery and one death.

Jejunostomy and invagination of ulcer. One case—death.

Partial gastrectomy and resection of anastomosis. One case—death.

Jejunal ulcer found perforated into colon. Colon and jejunum separated, holes closed, and gastro-enterostomy undone. One case—recovery.

Ulcer excised and gastro-enterostomy undone. Two years later large perforating ulcer on posterior wall of stomach. Partial gastrectomy done. One case—death.

Pylorectomy and partial gastrectomy. One case—recovery.

Gastro-colic fistula secondary to a jejunal ulcer developed two to three years after first operation. Ulcer excised. One case—recovery.

Eight months after first operation jejunal ulcer found and lateral anastomosis done. Four years later, on account of persistent pain, a partial gastrectomy was done. One case—recovery.

Suture of perforated jejunal ulcer. One case—death.

Anterior gastro-enterostomy and lateral anastomosis. One case—recovery.

Gastro-enterostomy undone. One case—recovery.

Cauterization of ulcer. One case—recovery.

Resection of ulcer and four inches of jejunum, and lateral anastomosis done. One case—death.

Medical treatment only. One case—recovery.

Nature of operation not stated. One case—death.

Jejunal ulcer found at operation, but left as patient was too weak for radical operation Patient was fairly well one year later, but still had pain.

Remarks on the Seven Deaths.—One died at end of operation. One died soon after excision of ulcer. One died from coma and convulsions two days after operation. Three died three days after operation. One died two weeks after the third operation done for perforation of stomach.

Second Operations Required for Intercurrent Lesions after Gastro-enterostomy.

Twenty-one of these operations—that is, 2.8 per cent.—were required among the 744 cases in which after-histories were given; 86 per cent. of the cases were between 30 and

60 years of age. Particulars of the individual cases are given as they could not be tabulated.

1. Yielding of sutures three days after first operation from acute dilatation of stomach. Repair done; death one day after.

2. Pain and vomiting seven days after first operation from strangulation of small intestine in paraduodenal fossa. Relief of obstruction done; death.

3. Wound broke down ten days after first operation. Repair done; death on second day.

4. Obstructive vomiting ten days after first operation from obstruction of efferent loop by adhesions. Lateral anastomosis done; recovery.

5. Vomiting thirteen days after first operation. Lesion not stated. Lateral anastomosis done; recovery.

6. Pernicious vomiting twenty-one days after first operation from strangulation of ileum by slipping. Relief of obstruction done; death on second day.

7. Persistent vomiting one month after first operation from obstruction of afferent loop by slipping. Lateral anastomosis done; recovery.

8. Obstructive vomiting one year after first operation from obstruction of efferent loop by adhesions. Lateral anastomosis done; recovery.

9. Pain and dyspepsia one and a half years after first operation. Duodenal ulcer still active. Division of pylorus and closure of both ends done; recovery.

10. Pain and vomiting one and a half years after first operation from omental adhesions. Enterolysis and entero-enterostomy done; recovery.

11. Vomiting one and a half years after first operation from vicious circle. Gastro-enterostomy undone and pyloroplasty done; recovery.

12. Pain two years after first operation from lesser curve ulcer. Gastrectomy done; recovery.

13. Pain three years after first operation from indurated mass at site of previous operation. Excision of mass and separation of adhesions done; recovery.

14. Pain, vomiting, and loss of weight three years after first operation from lesser curve ulcer. Patient too weak for radical operation, and medical treatment only employed. Result not stated.

15. Intestinal obstruction three years after first operation from adhesions; division of adhesions done; recovery.

16. Pain three and a half years after first operation from small ulcer on lesser curvature; cauterization of ulcer done; recovery.

17. Pain and vomiting four years after first operation from kinking of two loops of jejunum. Anastomosis between the two loops done; recovery.

18. Recurrent vomiting five years after first operation. Gastro enterostomy undone; recovery.

19. Pain five years after first operation from cholecystitis and gall-stone. Removal of gall-bladder done; recovery.

20. Pain five and a half years after first operation from adhesions. Adhesions separated; recovery.

21. Gastro-colic fistula seven years after first operation. Suture done; death one day later from shock.

Secondary Haemorrhage.

(Not stated as due to anastomotic ulcer.)

Number.—Eighteen cases of secondary haemorrhage—that is, 2.4 per cent.—occurred among the 744 cases in which after-histories were given.

Sex.—Males 16; females 2.

TABLE XX.—*Age Incidence.*

Age.	No. of Cases.
20-30 years	3
30-40 ,,	4
40-50 ,,	11

TABLE XXI.—*Nature of Haemorrhage.*

Nature of haemorrhage.	No of Cases.
Haematemesis	10
Melaena	5
Haematemesis and melaena	3

TABLE XXII.—*Periods at which Haemorrhage started after the Gastro-enterostomy Operation.*

Period.	No of Cases.
1-2 years	4
2-3 ,,	7
3-4 ,,	4
5-6 ,,	2
6-7 ,,	1

Treatment.—Sixteen had rest only, with or without medical treatment; 2 were operated on—1 resection of duodenal ulcer, and 1 entero-enterostomy for omental adhesions.

Results.—Good recovery in 13 cases; fair recovery in 5 cases. No deaths.

Analysis of the Post-operative Mortality.

Among the 995 cases of duodenal ulceration 11 deaths occurred from another lesion some years after the operation and quite unconnected with it. As these 11 cases up to the time of death were free from all symptoms connected with the ulceration the deaths are not included among the post-operative deaths.

The number of post-operative deaths out of the 995 cases was 50—that is, 5.0 per cent. These are the deaths that occurred as a direct result of the operation of gastro-enterostomy, and do not include the deaths from gastro-jejunal ulcers and from second operations performed for some intercurrent lesion, which have already been enumerated in the preceding part of this report.

Sex.—Of the 50 deaths, 86 per cent. occurred amongst males, and 14 per cent. amongst females—a ratio which is roughly that of the sex incidence of the disease.

TABLE XXIII.—*Age Incidence of Deaths.*

Age.	Percentage of Deaths.
20-30 years	12
30-40 ,,	10
40-50 ,,	41
50-60 ,,	22
60-70 ,,	12

TABLE XXIV.—*Time of Occurrence of Death After Operation.*

Time.	Percentage of Deaths.
1- 6 days	64
7-11 ,,	26
3- 4 weeks	4
4- 5 ,,	4
6- 7 ,,	2

Among the 50 cases haemorrhage (haematemesis, melaena, or both) occurred as a symptom prior to operation in 24 per cent. of the cases. It would appear from these figures that the risk of a fatal post-operative result is not increased by the occurrence of haemorrhage prior to the operation.

TABLE XXV.—*Cause of Death.*

Cause of Death.	No. of Cases.
Shock	11
Pneumonia	7
Haemorrhage	5
Cardiac failure (fatty heart)	5
Peritonitis	3
Pulmonary embolism	2
Cerebral embolism	1
Pneumonia and empyema	1
Bronchiectasis and empyema	1
Strangulation of intestine	1
Cause not stated	14

Carcinoma Developing at the Site of Ulcers.—No authenticated case was reported in the whole series. In one case carcinoma was *diagnosed* five to six years after the operation, but was considered inoperable; the patient died a few months later, but no post-mortem examination was allowed. In answer to a special letter, the medical practitioner who had been in charge wrote that *from the clinical* aspect of the case he considered that carcinoma developed at the site of the old ulcer, which at the operation had neither been invaginated nor excised.

General Observations by Surgeons and Medical Practitioners.

The second form requested an indication of the views of *surgeons and medical practitioners* as to the value of the operation of gastro-enterostomy.

Views of Surgeons.

Of the 86 surgeons who sent in returns, 37 filled in this second form. Their views as to the value of the operation for duodenal and pyloric ulcers are as follows:

Thirty six consider the operation of great value in cases of duodenal and pyloric ulceration associated with stenosis of the pylorus.

Six consider that, in addition to the operation, invagination, excision, or cauterization of the ulcer should be done.

Four consider the operation of great value in the treatment of perforated duodenal or pyloric ulcers in addition to closure of the perforation.

Three consider the operation of greater value when combined with closure of the pylorus.

Views of Medical Practitioners.

The second form was filled in by 153 medical practitioners. Their views as to the value of the operation for duodenal and pyloric ulcers are as follows:

One hundred and twenty-three consider the results of the operation to be very satisfactory in the great majority of cases.

Seventeen state that recurrence of pain and gastric disturbance occurred in many cases.

Thirteen state that recurrence of pain and gastric disturbance occurred in a few cases.

One considers that the operation is unfavourable in cases of simple duodenal ulcers without pyloric stenosis.

Brief Summary of Results.

Duodenal ulceration is about five times more common in males than in females.

The liability to duodenal ulceration rapidly diminishes after 50 years of age.

Posterior gastro-enterostomy, with or without embedding or removal of the ulcer, was the operation performed in 96.4 per cent. of the cases.

Hyperchlorhydria was present in 86.2 per cent. of the cases submitted to test meals.

Neither diarrhoea nor constipation is a marked result of the operation, but constipation of a mild character is more frequent than diarrhoea.

About one-third of the cases operated on made some slight modification in diet; of these, 60 per cent. avoided some form of protein, and 40 per cent. some form of carbohydrate.

About three-fourths of the patients returned to full work within three months of the date of the operation.

General improvement of health and well-being occurred in all but a few cases.

The results of the operation were satisfactory in about 90 per cent. of the cases.

Secondary gastro-jejunal ulcers occurred in 2.8 per cent. of the cases.

Secondary haemorrhage occurred in 2.4 per cent. of the cases, but with no fatal result.

The post-operative mortality was 5 per cent., the mortality being highest in patients from 40 to 50 years of age. The majority of deaths occurred within seven days of the date of operation.

No authenticated case of carcinoma developing at the site of an ulcer was reported in the whole series.

THE ROYAL SOCIETY.

President's Anniversary Address.

The 267th annual meeting of the Royal Society was held, according to custom, on St. Andrew's Day, November 30th. The President, Sir Ernest Rutherford, O.M., was in the chair, and delivered the usual anniversary address, in the course of which he mentioned the fourteen Fellows who had died during the year, and stated the grounds for the award of the Society's medals.

Deceased Fellows.

By the death of Sir Bertram Windle, M.D., the President said, the Society had lost a Fellow whose main activities were devoted to administrative work as principal of University College, Cork, and in his later years as professor of anthropology at Toronto. In his earlier days as professor of anatomy in Birmingham Windle carried out important researches in comparative myology, and wrote *interesting popular works on prehistoric Britain.*

Referring to the death of Mr. Walter Heape, the President said that he was one of the group of students who drew their inspiration from the school created by Francis Balfour at Cambridge. He introduced precision into the study of the embryology of mammals, and was one of the first to investigate the oestrous cycle and to promote scientific study of breeding and sexual physiology. Heape belonged to the class of scientific amateurs to whom science in this country had been so much indebted in the past.

Of Sir E. Ray Lankester, a Fellow of the Society for fifty-four years, the President naturally spoke at some length.

"There is scarcely a group of animals he did not study, scarcely a problem he did not help to elucidate, more especially in the morphology of the invertebrata. . . . A man of exceptional intellectual power, of deep insight and sound judgement, he was a great teacher, and for long the recognized leader among British zoologists. A picture of Lankester would be incomplete without reference to his vivid and impulsive personality. He was restrained, prudent, and temperate in scientific treatment, but in other contacts with the world, and especially with the official world, he was apt to be not only *fortiter in re* but *violenter in modo*. But these exuberances welled up from a generous heart, and were displayed only in what Lankester believed to be a just cause. He will be remembered not only as a great zoologist, but as a lover of all natural knowledge, a respecter of all serious workers in science, and a very strong help to his friends and pupils."

After indicating the great contributions to synthetic organic chemistry made by Dr. William Henry Perkin, Waynflete Professor of Chemistry at Oxford, the President said:

"All these achievements, remarkable as they seemed at the time, were surpassed by his work on alkaloids. Perkin early conceived the ambitious project of determining the constitution and effecting the synthesis of certain of the more complex vegetable alkaloids; his memoirs on this subject, by their insight into intricacies of molecular constitution, their grasp of experimental methods, and their attention to minute detail, opened a new epoch in organic chemistry. His ingenuity and pertinacity were rewarded by the synthesis of many of the naturally occurring alkaloids."

The Society's Officers.

The President next spoke of the retirement of two distinguished officers, Lieut.-Colonel Sir David Prain, I.M.S. (ret.), treasurer for ten years, and Sir James Jeans, secretary for an equal period. During their tenure of office, he said, the Society had greatly increased its responsibilities, mainly owing to the large bequests which resulted in the foundation of the Foulerton and Yarrow professorships.

"Sir David Prain has devoted himself wholeheartedly to the welfare of the Society; his wide experience of administration and breadth of scientific knowledge have been of much service on innumerable occasions. He has been ever ready to subordinate his own convenience, if he could thereby more effectively help the Society."

Sir David Prain is succeeded in the post of treasurer by Sir Henry Lyons, and Dr. F. E. Smith becomes joint secretary with Dr. H. H. Dale; Lord Rayleigh is now foreign secretary in the place of Sir Henry Lyons.

Before proceeding to his review of the advance of science, and particularly of the physical sciences, the President noted with gratification that three Fellows of the Society had this year received the award of Nobel Prizes—namely, Professor Arthur Harden, Sir Frederick Hopkins, and Professor O. W. Richardson.

Presentation of Medals.

The President then formally presented the Society's medals, and summarized the achievements of each medallist. The Copley Medal has been awarded to Professor Max Planck; Royal Medals to Professor J. E. Littlewood and Professor Robert Muir, M.D.; the Davy Medal to Professor Gilbert Newton Lewis; and the Hughes Medal to Professor Hans Geiger. In handing a Royal Medal to the Professor of Pathology in the University of Glasgow, Sir Ernest Rutherford said:

"Professor Robert Muir has for over a quarter of a century taken a leading part in the development of pathological and bacteriological research in this country. He is particularly distinguished for his pioneer work in the study of immunity reactions and mechanisms at a time when the foundations of the science of immunology were being laid, and the combining properties of normal and immune serums with antigen were being submitted to analysis by test tube methods. The schools of Ehrlich and of Bordet, which were then particularly active in this new branch of science, had their worthy counterpart in this country in that founded by Robert Muir in Glasgow, and during the first decade of the century there emanated from that school a most important series of contributions devoted to the elucidation of the interactions between complements and immune bodies on the one hand, and antigen on the other. Haemolytic systems were chiefly studied and problems concerned with the specificity, constitution, and dissociation of immune bodies and with the combining properties of complements were attacked by accurate quantitative methods. These studies by Muir and his collaborators are of fundamental importance in the history of the development of the science. They are embodied in Muir's *Studies on Immunity*, published in 1909, which contains a full discussion of their bearing on current theory. The pursuit of serological problems by many pupils working under his direction has been ever since successfully continued. Muir's interests, however, have not been confined to immunology. In the field of general and experimental pathology he has made important contributions to knowledge, and his researches on experimental anaemia produced by the injection of haemolytic serum, and on the regenerative changes in the bone marrow in response to infection, are widely known. In many other directions the work of Muir and his school has influenced the advance of pathology."

Scotland.

Bicentenary of the Royal Infirmary, Edinburgh.

A COMMEMORATION service was held in St. Giles's Cathedral on November 27th to signalize the foundation of the Royal Infirmary of Edinburgh on August 6th, 1729. The original infirmary was part of a small house near the head of Robertson's Close, containing 6 beds, in which 35 patients were treated in the first year. A special building was afterwards erected some two hundred yards away from the original site in 1741. This, again, was demolished in the latter part of the nineteenth century, and the present buildings were occupied in 1879, so that the year 1929 marks both the bicentenary of the original foundation and the jubilee of the occupation of the new buildings. A large and representative congregation assembled for the occasion in St. Giles's Cathedral. The service included the reading of a scripture lesson by the Lord Provost of Edinburgh, and an address by the Rev. Charles L. Warr, dean of the Thistle and Chapel Royal. The preacher declared that there was no more moving human experience than the evidence of unity of soul, which on such occasions blended the multifarious activities of a community into one, and demonstrated that collectively, as well as individually, it possessed a personality and a common ideal. A cynic might say that the care of the sick was a policy of practical social economy, but this was a warped and distorted definition. Two hundred years had passed since the birth of the Edinburgh Royal Infirmary, and to-day it was renowned as the largest voluntary hospital in Great Britain. A still greater future lay before the infirmary, and an enterprise of wider expansion was at hand which in due time would be brought to fruition by the broad and generous impulse of the citizens.

Mr. Russell Paton, the organizing secretary of the Royal Infirmary, spoke at a luncheon of the Edinburgh City Business Club, on November 26th, with regard to the future development of the infirmary. He said that a distinctive feature of the demand for increased hospital accommodation was in the direction of providing for surgical cases. Twenty years ago the number of surgical cases in the year was under 7,000, but in the present year their number had risen to 15,000. A total sum of not less than £300,000 would be required to cover the cost of new buildings on the site of George Watson's College adjoining the institution, and the additional annual expenditure required for these would be not less than £35,000. The infirmary in the present year had a record revenue from all sources, but the voluntary principle had to be judged strictly by results and in terms of efficient and adequate service rendered to the community. If the voluntary hospital system was to be continued it must, by methods of mutual adjustment, be largely free from the bestowal of charity upon poverty-stricken supplicants. A voluntary hospital must be a great social institution on the broad ethical principle of conferring its benefits upon all and receiving from all support according to their ability to pay. Sir Joseph Dobbie, who presided, said that the suggestion of a rate-aided hospital would be strongly opposed by the commercial community as striking a blow at one of the very finest examples of voluntary assistance rendered to a desirable object.

Ante-natal Clinics in Edinburgh.

Dr. William Robertson, medical officer of health for Edinburgh, recently submitted to the Public Health Committee of the city a report on the question of maternal mortality. He said that the problem of maternal deaths could be faced with greater confidence than the control of infantile mortality, because the preservation of the mother's life depended in the great majority of cases in allowing nature to follow its own course. As additional safeguards certain precautions should be taken before and after the birth of the child. The maternal mortality rate per 1,000 births had been 6.6 in Edinburgh during the last two years, as compared with Glasgow's 8.8 last year. In the case of Edinburgh the causes of death had been puerperal sepsis, puerperal haemorrhage, and puerperal eclampsia. Of the total 264 maternal deaths which occurred during the past eight years, these conditions caused 207 deaths. Between November 30th, 1928, and October 31st, 1929, there had been 7,389 births in the city, with 53 maternal deaths. The maternal death rate for the city, excluding 1,404 cases attended by nurses, had been 8.2 per 1,000, while in cases attended by nurses the maternal death rate had been 1.6 per 1,000. Statistical evidence went to show that no particular section of the population contributed more than another to maternal mortality, the rich suffering as much as the poor. If a good maternity service was to be established every city should appoint a panel of medical specialists, who would be at the immediate call of a nurse when she found herself confronted with a difficult or abnormal labour. The establishment of ante-natal clinics should be undertaken, and as regarded Edinburgh, he proposed the immediate provision of three more clinics of this kind.

The Mystery of Influenza.

Dr. James L. Halliday, assistant medical officer of health for Glasgow, speaking in that city on November 19th, said that during the first five weeks of the present year 2,500 people had died in Glasgow alone who would still have been living if there had been no outbreak of influenza. Influenza was not a recent disease, for there had been outbreaks of this kind at intervals of some twenty years ever since the Middle Ages. Since 1889 influenza has always been present in Britain, and particularly severe outbreaks had recently taken place in 1918, 1922, and 1929. The last outbreak had begun in California in the autumn of 1928, reached New York in December, Glasgow and Belfast in January, Edinburgh, London, and Manchester in February, and Birmingham in March. Li

SCOTLAND.

was known about the factors which made influenza virulent and dispersive. In a general way this was due to an upset of the symbiosis upon which the virus of influenza and man lived together. Examples of similar loss of balance between living things was a frequent phenomenon, of which such incidents as sudden plagues in caterpillars, field mice, and mosquitos were examples. In nearly all these cases the conditions producing loss of balance were unknown. There was a certain amount of evidence with regard to influenza that the prolonged maintenance of anti-cyclonic weather played a part. One of the greatest writers on the subject of epidemiology had referred to the problem of influenza as the crux of epidemiology. When they had come to an understanding of the factors which increased the virulence of the virus of this disease they would probably be able to deal with the problem of all other air-borne diseases.

Inverness Hospitals.

Representatives of the Scottish Department of Health, consisting of Dr. Duttnall, medical officer, Mr. Fraser, assistant secretary of the Department, and Mr. Wilson, chief architectural inspector, last week made a visit to Inverness with the object of discussing the question of the reorganization of hospital services with the representatives of the burgh and county of Inverness. Visits were paid to the Cuduthel and Munfield Hospitals, and to the small-pox hospital at the Citadel. A statement was made on the requirements of hospital accommodation for the burgh and county with a view to centralizing the treatment of infectious diseases, and to the provision for the sick poor under the terms of the Local Government Act. The necessary provision for the treatment of surgical cases, tuberculosis, venereal disease, and difficult maternity cases was also discussed. A conference was held between the representatives of the Department of Health and representatives of the town and of the board of the Northern Infirmary with regard to the possibility of erecting a block at the Infirmary for the accommodation of these types of illness. The general view was expressed that if the present buildings were reconditioned it would not be necessary to make further extension of the new buildings.

The Growth of the Mind.

The ninth annual Ramsay Henderson Trust Lecture was delivered on November 29th in the anatomy classroom of Edinburgh University by Sir Robert Armstrong-Jones, M.D.; Dr. Hamilton C. Marr presided. The lecturer dealt with the growth of the mind, and remarked that this was the centenary celebration of the trust deed executed by William Ramsay Henderson to assist in advancing knowledge of brain physiology, which in 1829 was referred to as phrenology or cranioscopy. Some persons used the term mind as equivalent to memory, while others used it as the equivalent of thought. John Stuart Mill and Thomas Reid of Glasgow had both presented well-thought definitions of mind. The Apostle Paul had apparently regarded mind as an awareness, while the spirit was a second mind employed in the contemplation of higher ideals. The mind consisted of a constant running stream of sensations and feelings, of which we were aware, while there was also involved a tendency to act in a certain way. A picture of the mind might be presented as a triangle within a circle, the triangle consisting of sensation, cognition, and will, surrounded by the circle of tendency, inherited or the result of education, sometimes described as configuration. Aristotle had believed that a human being consisted of five parts—the four elements, and a fifth, which was the quintessence of the others. The Viennese school of Freud did away entirely with the freedom of the will, explaining conduct as due to predetermined tendencies in the unconscious mind, a view which was not widely accepted. A later view was that the mind was a summation of conditional reflexes. It was interesting to trace the growth of the mind upwards from the simplest forms of the animal kingdom. In the lowest forms such as paramaecium, there was a definite avoiding reaction against objects, which suggested purpose. In the jelly-fish the rhythmical contractions of the swimming bell caused reflex movements, while the sea anemone exercised choice as to food. The earthworm showed sensation, motion, and reflex action, while insects were noted for their instincts, and molluscs could scent their food at a distance. In the vertebrate kingdom the fishes had a marvellous sense of smell, while reptiles led a more active and diversified life, and birds had highly developed instincts, especially about nest-making and breeding. In mammals the highest developed form of brain was reached, with the brain of man comprising 9,000 millions of neurons. It was marvellous that in such a delicate and complex organ so few of these structures became deranged. Man at birth entered into an unknown territory, which he might conquer if he had the right ideas, a proper feeling, and a determined will. These could be secured in the first place through the senses, which were the main avenues to the mind. The senses were probably about twenty in number, instead of the five usually accepted. It was thus most important to exercise care as to what entered the mind, especially in the case of the young, where the mind was wax to receive and marble to retain. Ideas in the mind were always associated with pleasure or otherwise, and this feeling helped the attention to recall them. The memory was regarded as an integral part of the intellect which went on after an impression had ceased and gave continuity to our thoughts. Every act of the will was an act of choice, and the first part of the will was attention. The habit of attention could be increased, and the most marked symptom in insanity was the failure to concentrate attention.

England and Wales.

Hospital Saving Association.

STRIKING evidence of the achievement possible under voluntary co-operative effort was afforded by the seventh annual report of the Hospital Saving Association, submitted to the annual general meeting at the Kingsway Hall on November 26th. In six years the number of contributors to this method of insurance for hospital benefit had risen from 62,000 to nearly 652,000: the groups which paid contributions to the association numbered 6,700: and nearly 7,000 group secretaries collected last year over 25,000,000 threepences, forming a total of £320,000, as compared with £249,000 in the previous year. During the twelve months about 172,000 contributors and their dependants were treated at voluntary hospitals, 31,000 being in-patients. The number of days of in-patient maintenance was 657,000; and the final distribution recommended at the meeting brought the direct payments to voluntary hospitals for the year to £193,000. It would appear, therefore, that if the out-patient treatment is regarded as gratuitous, the association pays somewhere about six shillings a day towards the maintenance in voluntary hospitals of every contributor or his dependant admitted. The costs of administration are less than 8 per cent. of the contributions. It is satisfactory to learn that the proportion of out-patients treated is going down, thus meeting to some extent one of the objections that have been made to the association's activities. Sir Alan Anderson, the chairman, expressed gratification that the Prince of Wales had become patron of the association. He called attention to the establishment of three eye clinics, which not only supplemented the accommodation available in the ophthalmic departments of hospitals, but also ensured that ophthalmic surgeons received a reasonable fee. The meeting of group representatives was afterwards addressed by Sir Humphry Rolleston. He emphasized the importance of voluntary hospitals, not only in treating actual disease, but also in educating students and nurses, in radiating medical knowledge, and in promoting skilled research. He thought that social work should be added to hospital work, and illustrated its value by describing the necessity for observation and after-care in acute and chronic rheumatism. A vote of thanks to the group secretaries was moved by Dame Helen Gwynne-Vaughan, and seconded by Mr. Ernest Bevin, general secretary of the Transport and General Workers' Union. The impression left by the meeting was that, if voluntary co-operation of big employers of labour, of workpeople, of hospitals, and the medical profession could reach such dimensions, it was a pity that the same

inciple could not be extended in other directions. Among e group representatives there must have been many upporters of the political party which aims at the nationlization of hospitals; yet in their evident enthusiasm or the Hospital Saving Association, they would appear o be giving moral and financial support to the mainenance of the voluntary system. And the scheme, as far as ould be gathered, is worked with a minimum of friction.

Greater London Regional Planning.

The Minister of Health (the Right Hon. A. Greenwood, M.P.), who was accompanied by the Parliamentary Secretary of the Ministry of Transport (Earl Russell), received last week a deputation from the Greater London Regional Planning Committee. The first object of the deputation was to ask that the Government would take steps to check the evils of ribbon development on arterial roads. A further question with which the committee had been concerned—the reservation of land for recreation grounds and other open spaces—was closely connected with that of ribbon development, since much the same difficulties arose with regard to the control over the land in question. The committee suggested that these difficulties might be largely solved by amendments in the Town Planning Act, and it submitted a memorandum on the possibility of reserving a green belt around London, together with some specific suggestions for the amendment of the Act, calculated to facilitate the reservation of land from buildings and the provision of open spaces, without imposing heavy burdens on the ratepayers. The Minister of Health said, in reply, that he greatly appreciated the work undertaken by the London Regional Planning Committee, and he was in full agreement with its general objects. The committee's proposals for the reservation of open spaces and, in particular, of a green belt around London, were of great interest, though the methods to be adopted in practice would need careful examination. He was also interested in the suggestion that a special regional planning body should be constituted for the Greater London area; but that, he thought, was a matter on which it would first be necessary to obtain the views of the local authorities concerned. Lord Russell said that he fully sympathized with the views which the deputation had expressed upon the undesirability of ribbon development, from considerations both of economy and of traffic requirements, and the committee would have every support from the Minister of Transport in any practical scheme for mitigating the evil.

Infant Life Protection.

As is now fully appreciated, the councils of county boroughs and of counties have, under the Local Government Act, 1929, the option of carrying out functions transferred to them either under the Poor Law or under the appropriate special Acts relating to such matters, though they are required to adopt the latter alternative "as soon as circumstances permit." There are, however, two functions with regard to which the Act gives them no such option. Under Section 2, functions relating to vaccination must be discharged as functions relating to public health, and functions under Part I of the Children Act, 1908, must be discharged as functions under the Maternity and Child Welfare Act, 1918. Moreover, "where the council of a district have established a maternity and child welfare committee the said functions shall, in that district, be discharged by the council of the district and not by the county council." The Ministry of Health has now issued to all maternity and child welfare authorities a memorandum (L.G.A. 28) with regard to the duties which under this section, they will have to undertake as from April 1st, 1930. The main object of Part I of the Children Act is to secure that any child under 7 years of age who is maintained "for reward" shall be notified to the local authority in order that it may be kept under observation and supervision. Every person who undertakes such maintenance, except relatives ("grandparents, brothers, sisters, uncles, and aunts") or those in charge of hospitals, boarding schools, or certain institutions, must, within forty-eight hours of the reception of a child, give to the authority written notice, stating the name, sex, and date and place of birth of the infant, the name of the person receiving it, the dwelling wherein it is kept, and the name and address of the person from whom it was received. The local authority must keep a complete register of such cases and must appoint infant protection visitors, who shall visit the children and satisfy themselves that they are properly nursed and maintained. Where infants are placed out by a philanthropic society, the society may itself be appointed to act as visitor. The local authority may fix the number of children under 7 years of age who may be kept in premises of which notice has to be given; and there are further provisions with regard to certain persons or premises in respect to whom or which special sanction is required from the authority, with regard to removals, and with regard to procedure in the event of the death of an infant. Persons guilty of offences under Part I of the Children Act are liable, on summary conviction, to imprisonment for not more than six months or a fine not exceeding £25. All these matters will from April next stand referred to the maternity and child welfare committee of the local authority, and in most cases, no doubt, the health visitors will be appointed as the infant protection visitors. It is suggested by the Ministry that where necessary such visitors should at once be given appropriate instruction in the new duties which they will have to undertake.

Extension of the Cancer Hospital, London.

A scheme of extension has been resolved upon by the Cancer Hospital, Fulham Road, London. A new wing is to be built and certain adaptations made in existing wards which will result eventually in the addition of about eighty beds, bringing the total to two hundred beds. The radiological department, of which for many years the late Dr. Robert Knox was director, is to have new and larger quarters. The new wing, the plans for which have just been approved and the site cleared, will be a building of six floors. On each of the three lower floors there will be six single-bed wards, one or two two-bed wards, and one three-bed ward, making in all thirty-seven beds; these are intended for paying patients. The three upper floors are to be devoted to the electrical and x-ray work of the hospital. Here will be provided a large electro-therapeutic room, with space for seven cubicles, radiography rooms, rooms for deep and medium x-ray therapy, radium workrooms and emanation rooms, a physics laboratory, dark rooms, and all necessary installations for photography and experiment. Films will not be stored in the main building, but in a small detached building in the grounds. In addition to the beds provided by this new block, several other extensions and conversions are projected which will give immediately twelve, and ultimately forty-four, new beds. The cost of the new block alone is estimated at £57,000, but, in addition, much other reconstruction will be necessary, together with increased staff and maintenance charges, and an appeal is being made for £150,000. One of the features of the new scheme will be the provision for out-patients, for whom there will be a central hall, consulting and examining rooms, and other conveniences in the basement of the new wing. An advanced course in radiology at the hospital, a new departure, is to begin in January and to continue until April. The course will consist of lectures and practical work, with demonstrations in both the laboratories and the hospital, and will be given by the radiologists, the physicist, and other members of the staff. It is stated that the course will be on a larger scale than has been attempted before in London; it will deal first with the physics concerned, and then thoroughly explore the medical and surgical aspects.

Women Poor Law Guardians and the L.C.C.

A largely attended "at home" was given at the Forum Club, Hyde Park Corner, on November 28th, in honour of the work done by the women Poor Law guardians of London. Under the Local Government Act Poor Law authorities will cease to exist next April, but it is hoped that many who have done useful work on those authorities will be co-opted on to the committees that are to take their place. Women representing twenty-five metropolitan boards of guardians were present on this occasion. Dr. Florence Barry Lambert, chairman of the new Central Public Health Committee for London, gave an address in which

said that for the London County Council to come into that arena was suggestive of the lion lying down with the lamb; she could assure her audience, however, that the L.C.C. was a very benevolent and an intensely grateful lion, grateful not only for what had been received from the guardians in the past, but for the favours that it was hoped were to come. Unless the scheme received the hearty co-operation of the former guardians it would not result in the expected success. One objection which many women had felt at the outset, added Dr. Lambert, was that the Central Public Health Committee for London was constituted, even as regards its co-opted members, on party political lines. This was because the London County Council was a body, where, at present, the Municipal Reformers were in power, in consequence, all committees were formed on a basis which gave the numerical advantage to that party. But apart from the initial question asked of candidates for co-option as to what their party affiliation might be, politics entered very little into the Public Health Committee. The task before that committee was a very large one. Hitherto the county council had "farmed out" its hospital services by means of arrangements with the Metropolitan Asylums Board and other bodies, but now it became the largest of all hospital authorities. One of the subcommittees would have to deal with all the (hitherto Poor Law) infirmaries, another would supervise practically all the hospital services hitherto controlled by the Metropolitan Asylums Board; another would have under its purview the ambulance services; and still another would be concerned with the planning and development of hospitals. Staff matters would require very detailed attention, owing to the extraordinary differences prevailing among those in the nursing services for example, as to pay and conditions of service. For hospital purposes London would be classified into five areas, each of which would have its local hospital committee. The speaker hoped that the services which had been so freely given on boards of guardians would still be available.

Presentation to Dr. G. S. Pollard.

In view of his retirement and departure from Midsomer Norton, in Somerset, a public presentation was made recently to Dr G. S. Pollard, J.P., who has carried on an extensive practice there for over forty years, and has been honorary medical director of the Paulton Hospital for twenty years. The Countess Waldegrave, on behalf of the subscribers, handed to Dr. Pollard a handsome inscribed silver salver and a cheque. The chairman of the urban district council, who presided at the presentation, spoke warmly of Dr. Pollard's manifold services to numerous local interests, such as the nursing association, of which he had been chairman, the council schools, the British Legion, St. John Ambulance, the British Red Cross Society, various agricultural exhibitions, and the Volunteer and Territorial Forces. Dr. Pollard was president of the Bath and Bristol Branch of the British Medical Association in 1922-23, and a member of the Branch Council for the periods 1901-5, 1909-11, and 1924-26. He was also chairman of the Bath Division in 1910, and vice-chairman in the following year, subsequently serving on the Executive Committee of the Division from 1922 to 1923. For many years he was medical officer to Downside Abbey and College, and in this connexion received an additional presentation a few days later.

India.

Medical Missions in India.

A survey of the medical missions in India was planned in 1924, and conducted during the succeeding years by the Medical Missionary Association of India, in conjunction with the National Christian Council of India, Burma, and Ceylon, with a view to increasing co-operation and determining the best lines of future progress. Visits were paid to various hospitals, and the appropriate Government and medical statistics were investigated. In the report of this survey, which has recently been issued, attention is called to the essential importance of medical missions in evangelization and the necessity of securing the best skill and equipment available. A chapter on the general situation as regards medical relief emphasizes the vast extent of the field awaiting cultivation. Thus, the province of Bengal, with a population of more than forty-six million inhabitants, has only nine mission hospitals, and in the United Provinces, with a population nearly as great, there are fourteen. In Central India there are twenty-six small States, with a total population of four and a half million, and no medical missionaries. It has been estimated that there are at least 100 million persons in India for whom no scientific medical relief is available. A very interesting account is given of the work in mission hospitals, but the general lack of preventive medicine and of research is mentioned with regret; explanations of this, which were submitted in various centres to the inquirers, included inadequacy of the staff, money, and laboratory equipment, but it is admitted that the establishment of research centres by the Government has rendered the failure as regards research less serious than it otherwise would be. A practical chapter entitled "Conclusions" deserves close attention. Hints are given how to increase efficiency and to overcome the depressing influence of financial stringency and lack of co-operation between medical mission centres. Medical missionaries going to India are recommended to take the course of tropical medicine at Calcutta, and those on furlough are advised to make greater use of the existing post-graduate facilities, more of which are said to be necessary. It is suggested that medical mission recruits should, as far as possible, be appointed to definite hospitals, with a view to remaining there permanently; they should be transferred to other hospitals only exceptionally. The whole report invites the careful study not only of medical missionaries, but also of all who are interested in medical work in India. It contains a large amount of detailed information and practical hints, and also a list of mission hospitals in India, Burma, and Ceylon, with statistical notes in each case. Dr. E. Muir describes the operating of what he terms the "Propaganda-treatment-survey centre": a new field for medical missionaries." This has been found a most successful method of dealing with leprosy, and he thinks it might well be applied by medical missionaries to other diseases. The report is published by the National Christian Council, 1, Staveley Road, Poona.

Infant Welfare in Bombay.

Year by year a low birth rate is recorded in the city of Bombay, and Dr. J. E. Sandilands, executive health officer, in his annual report for 1928, thinks that this may be ascribed in part to the custom of married women leaving the city for their confinements and registering their children subsequently in the districts where they are born. The number of births registered in Bombay in 1928, however, exceeded that of the previous year by over 2,000; it was more than 3,000 above the annual mean number of births registered in the ten years 1918-27. Calculated on the estimated population for 1928 the birth rate was equivalent to 18.5 per 1,000; the number of live births recorded was the highest since 1866. The death rate among infants under the age of one year was 311 per 1,000 registered births, a figure which contrasts sharply with the calculated infantile death rate of 176 per 1,000 for the whole of British India, but is an improvement on 316, the 1927 rate, and on 474, the annual average in the decennium 1918-27. For many years active measures have been in progress to reduce this mortality. The Bombay municipal district nurses visit prospective mothers with a view to detecting signs of illness; they inquire into the condition of newly born infants, and give simple instruction as regards their rearing. In view of the fact that in about 40 per cent. of confinements there is no medical or nursing attendance, the importance of such visits is obvious. Attempts are being made to arrange for more general supervision of confinements by skilled midwives, and the visiting nurses endeavour to persuade prospective mothers to enter the maternity homes, where accommodation is provided for them without charge. When these offers are refused the nurses attend the women in their own homes, providing them with bedding for their confinements, and with milk and bread during the first days of the puerperium. Such visits often reveal entire ignorance

on the part of the women as to the facilities available for them; the nurses are therefore usually welcomed, and their services are highly appreciated. Nine centres have been established by the Infant Welfare Society, through its maternity and child welfare scheme. At these centres advice is given to mothers as regards infant management, medical aid is available for infants, and arrangements are made for trained nurses to visit the homes.

Correspondence.

THE CONSTITUTIONAL FACTOR IN EPILEPSY.

SIR,—Dr. James Adam, in his letter published in your issue of November 23rd (p. 982) has widened the discussion in this correspondence. He complains of the use of the word "constitution" as a synonym for "heredity," and asserts that constitution depends on heredity, nurture, and infection, and the immunity resulting from infection. But does not the immunity result from the constitution? May or may it not be transitory? Individuals react variously to noxious agents. One man after a surfeit of port will suffer from a short temper and a swollen, painful joint; another will be torpid, have a "fat" head, and a thick tongue. There may be also a family history of gout in the first case, and a negative family history in the second. It is usually assumed that the first man has a gouty constitution—a metabolic make-up tending to produce uric acid in excess, and the second a normal constitution. Both constitutions are inherited, but constitution is not the same entity as inheritance. Inheritance or heredity has a wider and a different connotation, and implies a physiological process of genetic continuity which is as applicable to a general make-up as to some minor anatomical defect. The term constitution itself is only a vague word which cloaks our ignorance of the workings of the body, but it is itself sufficiently definite as to have a distinct meaning, and its relation to heredity is so well understood that it would only confuse and befog the modern outlook of clinical medicine if it included the effects of nurture or infection.—I am, etc.,

Warrington, Nov. 27th. J. S. MANSON.

CALCIUM CONCENTRATION AND THE ACTION OF DRUGS.

SIR,—To your remarks in the *Journal* of October 19th (p. 727) concerning the work of Minot and others might have been added the fact that for many years now it has been demonstrated that hearts perfused with a low calcium solution show a sensitiveness to drug action far beyond anything observed on balanced Ringer's solution. For example, strychnine and sparteine reveal themselves as cardiac depressants when an ordinary balanced Ringer's solution is used, but a heart perfused with such a balanced Ringer's solution is so insensitive to drug action that, to get any effects at all from these drugs, concentrations have to be used which no physician would dream of reproducing in his patient's blood. The experimental use of such high concentrations would, of course, be perfectly justifiable if the effects of high and low concentrations differed only quantitatively; this, however, is not the case. Use of a low calcium perfusion shows that these drugs only depress at relatively high concentration, whereas at dilutions of the order of one part in one million or more they markedly stimulate. The dilutions at which these drugs stimulate cardiac activity, when perfused in a low calcium solution, are of the same order as those generated in the patient's blood by the measures of the physician. The clinical reputation of these drugs as cardiac stimulants has thus experimental justification. At the same time, it seems possible, taking into account Minot's results, that calcium deficiency may be present in those cases in which these drugs are of marked benefit. So far also I have invariably found, when perfusing through hearts drugs dissolved in a low calcium solution, not only all the phenomena observed by others who used balanced solutions, but something more that is usually obtained at clinically permissible dilutions, and is frequently of a different order from that observed on balanced solutions.

So far as perfused hearts are concerned, then, there are two groups of drug action—those of concentration and those of dilution. Both groups are obtainable when the calcium of the perfusing solution is low, but one only may be observed when the solution is "balanced" in respect of calcium. It happens also that the group of concentration effects is so much more easily observable than those of dilution that pharmacologists have, on the whole, given them chief attention. It would appear desirable to give the other group attention as well.—I am, etc.,

W. BURRIDGE,

Medical College, Lucknow, Nov. 14th. Professor of Physiology, Lucknow.

THE NEOPLASTIC ORIGIN OF THE LEUKAEMIAS.

SIR,—In connexion with my remarks in your issue of November 16th (p. 892) on the neoplastic nature of erythraemia, might I be permitted to add that one of the arguments most frequently brought forward (even by haematologists, such as Professor O. Naegeli of Zürich in the last edition of his textbook) against the neoplastic theory of the leukaemias (myeloses and lymphadenoses) is that the infiltration of organs, such as the liver, is not like that in cases of malignant tumours? The leukaemic cells infiltrate between the cells of the organ without destroying them and without exciting a defensive reaction. This consideration has been widely accepted as a most important objection, whereas in my opinion it constitutes the most important argument in favour of the neoplastic theory. I will briefly explain myself as follows: the cells of a malignant neoplasm endeavour to continue the functional characteristics of the normal cells from which they have originated. This is now almost generally admitted. (I endeavoured recently to sum up the observed facts in this regard at the commencement of a paper on endocrine tumours.[1]) One of the functional characteristics of blood cells is that when they are extravasated or wander into the various tissues of the body they do not destroy the latter and excite little or no defensive reaction; and this holds good in regard to leukaemic cells. Far from this consideration being antagonistic to the neoplastic theory of the leukaemias, it is, I repeat, an argument in its favour. (In a note on the theories of leukaemia[2] I wrote: "I would answer that, in regard to neoplastic diseases, evidence of . . . tissue reaction probably depends on the source of origin and nature of the tumour cells, and that tumour cells derived from (allied to) myeloblasts and lymphoblasts apparently excite no reaction of the kind.") There are naturally apparent exceptions, as when dense leukaemic "growths" in the bone marrow, as may be seen in rare cases, cause bone absorption by their pressure and give rise to thinning and even distension of the cortical bone.—I am, etc.,

London, W.1, Nov. 20th. F. PARKES WEBER.

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

SIR,—I find it somewhat difficult to take Dr. Webster's last letter (November 23rd, p. 983) seriously, or to accept as valid argument his mere *ipse dixit*, to the effect that "it can't be so, because I say it can't." He affirms that we (and presumably Mr. Stanford Cade also) have "entirely failed to prove that the use of fluorescein gives any better results than x rays or radium used alone," and in support of this sweeping statement he proceeds to quote the work of Birch-Hirschfeld. Surely, however, he does not intend to convey the suggestion that a corneal ulcer is allied to a malignant growth; but, if not, what is the value of his statement that because fluorescein + irradiation is apparently useless in the treatment of corneal ulcers, "How much more is this likely to be the case in malignant disease?" Obviously he has not appreciated the point of our contention that the action of fluorescein, when irradiated, is selective as between malignant and non-malignant tissues.

[1] *Proc. Roy. Soc. Med.*, Section of Medicine, 1928, xxii, p. 9 (see also *British Medical Journal*, 1928, ii, p. 533).
[2] *Brit. Journ. Child. Dis.*, 1926, xxiii, p. 189.

We thank Dr. Webster for the references he gives, but it is perhaps only fair to mention that my colleagues and I are not as ignorant of the literature of the subject as he would seem to infer; while as regards the physical problems involved we have sought the best advice available. Dr. Webster mentions that he has "tried fluorescein" without result, but he does not make it clear that his trial was concerned with one case only. Dr. Gouldesbrough will himself deal with Dr. Webster's renewed criticism of the radiological technique involved.—I am, etc.,

London, Nov. 20th. S. MONCKTON COPEMAN.

RACE PREJUDICE.

SIR,—The reference to race prejudice on September 14th (p. 505) brings to my mind two sets of facts.

In New Zealand it appeared after the Maori wars that the fine Polynesian race was doomed, and in the nineties the elimination of these natives seemed fairly certain. They have, however, become New Zealanders, and are steadily increasing in numbers. The half-castes are also increasing and are in many cases thoroughly efficient citizens. There is no colour line and no race feeling; intermarriage takes place as a normal practice. The following table illustrates the position.

Year.	Maoris and Half-castes	Year	Maoris and Half-castes.
1857	56,044	1901	45,550
1874 . .	47,330	1906	50,300
1878 .	43,595	1911	52,723
1881	44,097	1916	52,937
1886 .	43,927	1921	56,987
1891 .	41,177	1926	63,670
1836	42,113		

Half-castes as far as can be ascertained.

1891	4,800
1901	5,510
1911	7,000
1921	7,350*

* Of these, 4,200 are said among Europeans.

In Honolulu all opinion is favourable to the mixture of Chinese and Hawaiians; it is even claimed that the offspring inherit the good qualities of both races.

It is evident that the prevailing prejudice against half-castes has no solid foundation: the result depends not on colour but largely on the quality of the mixing races. It must, however, be remembered that in New Zealand a large British population has absorbed a relatively small Polynesian civilization, and in Honolulu the number of Chinese Hawaians is comparatively small—namely, 10,000. But to the imaginative it would appear that as civilizations develop and the conditions of life and the outlook approximate, it may well be that successful fusions will become more frequent.

The recent Pan-Pacific Surgical Conference held in Hawaii taught those Europeans who had any doubts on the subject that educated Chinese, Koreans, or Japanese can quite hold their own in medical efficiency with Caucasians. There is no monopoly of scientific ability. For the future of a troubled world containing some sixty nations it may well be hoped that a gradual levelling up and equalization process may be successful.—I am, etc.,

Melbourne, Oct. 22nd. JAMES W. BARRETT.

POST-GRADUATE OPPORTUNITIES IN LONDON.

SIR,—The views on post-graduate opportunities in London as expressed by your Wellington correspondent on October 19th (p. 735) must surely surprise anyone who has visited the city in recent years. If there was previously any lack of organization this has been remedied by the work of the Fellowship of Medicine and Post-Graduate Association. Its excellent programme is regularly published in the *British Medical Journal* and elsewhere, so there would appear little excuse for men to be ignorant of its work. Comparisons may be objectionable, but have been challenged. Friends in this country who have had experience of visits to London and other British University towns, as well as to those of the United States, inform me that the former possess many advantages, one of the chief being that sessions are punctual and dependable, and that they are held as published. Not one of those with whom I have spoken has ever complained of finding the English surgeon or physician unapproachable, while to say that there is any difficulty in making contact at the British Medical Association headquarters is simply preposterous. Even one of the ordinary rank and file meets with a ready welcome from the ever genial Medical Secretary or from one of the willing staff. At least that has been my personal experience and that of others from this country. Maybe the opening of the Library and Common Room till a late hour in the evening would satisfy a want in providing a centre for study or for recreative conversation. It would appear that the article was written by one visiting London in dim, dark ages, but it is a pity that the name of our late President should be apparently associated with such an expression of opinion.—I am, etc.,

Melita, Manitoba, Nov. 6th. NOEL R. RAWSON.

THE BURDEN OF DEAFNESS.

SIR,—A note of warning is necessary with regard to the "electrical aids to hearing," which are put on the market and advertised on purely commercial lines. Their makers, unlike those of surgical instruments, do not purvey their wares through or by the orders of the medical profession, and they have, naturally, no knowledge of the pathological conditions they so flamboyantly promise to "cure." The result is that a great deal of harm is being done to deaf persons, who are beguiled by specious advertisements. Often the instrument purchased, with or without a "trial," is useless, or the noise makes it unbearable to the patient. Often also, while the instrument helps the deaf person to hear better, he continues to use it frequently to the serious detriment of his natural function of hearing, which in the majority of cases can be improved or cured by proper treatment. The only types of deafness suitable for such an electrical appliance are those due to established otosclerosis or degeneration of the auditory nerve, but persons suffering from these conditions should be properly fitted with an instrument ordered by the aural surgeon, just as patients with defective eyesight are (or should be) provided with glasses on the prescription of the ophthalmic surgeon.—I am, etc.,

Bath, Nov. 24th. H. NORMAN BARNETT.

THE ACETIC ANHYDRIDE TEST IN CEREBRO-SPINAL FLUID.

SIR,—In an article in the *British Medical Journal* of November 23rd (p. 953) Dr. Freda K. Herbert cites my work among that of others who have investigated the cerebro-spinal fluid by means of the "Boltz test." I was, I believe, the first person in this country to apply this test and appreciate its value in the diagnosis of neuro-syphilis, and in 1925, at Bristol, I read a paper on the subject before the Royal Medico-Psychological Association, which in the same year was published in the *Journal of Mental Science*. Dr. Herbert derives conclusions about the value of the "Boltz test" from a series of "twenty-four cerebro-spinal fluids from various cases"; my own series has, up to date, included between 250 to 300 cases of organic and non-organic disease, syphilitic and non-syphilitic, in persons of different ages, and in every case the result of the Boltz test has coincided with that of the Wassermann reaction. The tests depending on the precipitation of protein did not give the same result. I suggest that the Boltz test is not a "crude" test, but a reliable, easily performed test for the investigation of neuro-syphilis. The coloration is due most probably to the presence of cholesterin in the cerebro-spinal fluid.—I am, etc.,

S. GROSSMAN, M.R.C.S., L.R.C.P.,

November 25th. The Royal Eastern Counties' Institution, Colchester.

RELIEF OF PAIN IN LABOUR.

SIR,—I am glad to read Dr. J. S. M. Connell's support for this principle (November 23rd, p. 982), though the avertin method he describes appears only to diminish the suffering, and apparently leaves the patient with the memory of it, so that it gives but a partial relief. I venture to suggest also that Dr. Connell is not quite consistent, in that he deliberately allows some avoidable suffering "in order that she may appreciate the relief which she is to get." It seems to me (1) wrong in principle, (2) that her

gratitude might be still further increased by being spared this unrelieved suffering, and (3) that a highly sensitive patient might find this quite sufficient to rule out a further pregnancy.

With regard to Dr. Elisabeth Rolston's letter (November 30th, p. 1031), sensitiveness to pain, and the capacity for bearing it, vary very widely. As to the cause, surely one need only study the mechanism of labour, the powerful muscular contractions against resistance, compression of soft parts by and against hard surfaces, and stretching of soft parts; the process is not essentially different from any other form of mechanical damage or injury to the body. To attempt to relieve or remove such pain by "adjusting the calcium content of the blood, or some other rational means," would only be another way of influencing sensibility to pain, or, as Dr. Rolston puts it, "doping the nervous system." If such an alternative could be found its application would by no means be limited to obstetrics.—

I am, etc.,

F. CURNOW PLUMMER.

London, N.W.8, Nov. 30th.

THE MENTAL TREATMENT BILL.

SIR,—The provisions of the Mental Treatment Bill just introduced into the House of Lords should be closely scrutinized before allowing it to pass into law—more especially those relating to detention and to the enormous powers placed in the hands of the Board of Control in reference to the approval, inspection, and regulation of any places in which slight or early cases are housed or treated without restriction of their liberty.

A very important pronouncement was made on this matter by the Council of the British Medical Association as reported in the *Supplement* to the *British Medical Journal* of April 29th, 1928 (p. 169):

"The Council desires to emphasize the existence of forms and degrees of mental disorder which need not bring the patients under the Lunacy Acts or within the cognizance of the Board of Control. These patients are conscious of some degree of mental disorder and desire to be treated, but do not, either in their own interests or in the interests of the public, require compulsory restriction of their liberty. They can be satisfactorily treated at out-patient departments, or in general hospitals, or by private practitioners in their own houses or in nursing homes. As a fact, they are so treated at the present day, although the existing provision for treatment of this order, and especially for the poorer patients, is quite inadequate, and ought to be increased. If the suggestion on page 150 of the [Royal Commission's] report regarding arrangements for treatment 'without certification' is to be read as a proposal to bring these patients in any way under the Board of Control, then the Council is bound to disagree. Such a formality, with the consequent prospect of official visits on behalf of the Board of Control, is quite unnecessary, and would certainly deter many patients from accepting the medical treatment they require. . . . The Council . . . reaffirms its opinion that the cases here considered ought not to be brought within the jurisdiction of the Board of Control."

—I am, etc.,

S. E. WHITE, M.B., B.Sc.

London, E.12, Nov. 29th.

*** The text of the Mental Treatment Bill will be found in the *Supplement* (p. 247), and the second reading debate in the House of Lords is reported by our Parliamentary Correspondent in the next column. The Association's Committee on Lunacy and Mental Disorder is meeting at the close of this week to consider the bill.—Ed., *B.M.J.*

ROYAL MEDICAL BENEVOLENT FUND GUILD.

Christmas Gifts.

SIR,—May I ask the hospitality of your widely circulated *Journal* to appeal for the Father Christmas Branch of the Royal Medical Benevolent Fund Guild. Christmas is drawing nigh and cupboards will be emptied to make room for prospective new gifts. We shall be very glad to receive any superfluous toys that may be discarded for new treasures, especially small gifts for boys and girls over 8 years old. Books and games of all descriptions will be appreciated, also gifts such as stockings, socks, mufflers, gloves, bags, handkerchiefs, and anything else suitable for working boys and girls. Money is preferred, as we can often take advantage of the generosity of the shops to send presents such as eiderdowns, blankets, and sheets to our elderly beneficiaries and thus save postage—a very heavy item.

Money and gifts should be sent, before December 12th, to the honorary treasurer, Miss Swinford Edwards, 63, Grosvenor Street, W.1. Children may become members of the Father Christmas Branch by sending a gift, or 2s. in lieu of a gift; and grown-ups by sending a gift, or 5s.—I am, etc.,

MARY TWEEDY, President.

London, W., Nov. 29th.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THIS week the House of Commons has made considerable progress with the examination of the Unemployment Insurance Bill in committee. A second reading was given to an Indemnity Bill to abrogate the penalties resulting from the fact that the Government had included seven Under Secretaries of State in the House of Commons instead of six, the legal maximum. In the arrangements to rectify this mistake Dr. Drummond Shiels has become Parliamentary Under Secretary to the Colonial Office.

On November 28th the Parliamentary Medical Committee visited the Government Lymph Station at Hendon. They saw the process of vaccination of the calf, the collection of lymph, the system whereby it is kept in cold storage for two years till cultures are practically sterile, and its testing on rabbits. Subsequently the committee visited the Field Research Laboratories of the Medical Research Council at Mill Hill, and were shown the research work in progress into distemper and into Johne's disease in cattle, as well as some of Dr. Gye's cancer investigations.

The second reading of the Children and Young Persons (Employment and Protection) Bill was moved by Mr. Sorensen in the House of Commons on November 29th. The motion was seconded by Dr. Marion Phillips and discussed by Mr. Clynes and Dr. Vernon Davies. In answer to a question by Mr. Sorensen, the Deputy Speaker (Mr. Dunnico) said that if the bill passed the second reading it would block legislation contemplated by the Government. Mr. Sorensen thereupon asked leave to withdraw his bill. It was, however, further discussed by Dr. Fremantle. Finally the House adjourned the debate, and the second reading was again formally set down for December 13th.

On December 3rd the House of Lords passed the Widows', Orphans', and Old Age Pensions Bill through report and third reading, and returned it to the Commons.

Mental Treatment Bill in the House of Lords.

Debate on Second Reading.

The second reading of the Mental Treatment Bill was moved in the House of Lords, on November 28th, by EARL RUSSELL, who said he had been chosen to represent the Minister of Health because of his experience as chairman of Hanwell Asylum, and, later, as a member of the Royal Commission on Lunacy, which had reported in 1926. The bill dealt with important parts of the recommendations of the Commission, but did not create a new code. The Commission had recommended that as desirable, but the Government was reluctant to undertake too comprehensive a bill on account of the difficulties of parliamentary time. The Government would welcome any amendments which the Lords could suggest to the bill, though it had been considered by successive Ministers of Health, and the present Government believed it the best solution. The Mental Treatment Bill which Lord Onslow had introduced in 1925 was based on the same principles. The Royal Commission had said in its report that "The keynote of the past has been detention; the keynote of the future should be prevention and treatment. . . . Certification should be the last resort in treatment, not the prerequisite of treatment."

Earl Russell said the Commissioners of Lunacy had pointed out, as far back as 1860, that the chances of recovery were far greater when the patients were placed under treatment at an early stage of the attack. Dealing with the present position, Sir Frederick Wills, a former chairman of the Board of Control, had written: "The evolution of asylums from mere places of detention to real hospitals had taken place." An asylum was no longer a place where a man was confined so that he could not do harm to himself or others. It was a place for curative

treatment, in the hope that the patient would be enabled to rejoin his fellow-men. Sir Frederick Wills had furnished statistics showing that the incidence of insanity had not been materially reduced. The change per 10,000 of the population was from 4.07 first admissions in 1869 to 4.48 in 1926. The rate for recovery per 100 admissions had improved since, but not as much as could be desired. The Government hoped that if the bill were adopted the number of recoveries might be improved. The technical recovery rate per 100 certified persons might become worse, because the Government hoped the people who were successfully treated under the bill would never become certified lunatics.

Earl Russell Explains the Bill

Turning to the bill itself (of which the text appears in the *Supplement* this week) Earl Russell said Clauses 1 to 4 related to the voluntary boarder, a person sufficiently intelligent to ask for and to wish for treatment. Clause 5 dealt with the temporary boarder, who had to be treated against his will, but only for a time. Clauses 11 to 15, to which great importance attached, reconstituted the Board of Control, which was now constituted under an Act of 1815.

By Clause 1 a person suffering from mental disorder desirous of voluntarily submitting himself to treatment might make a written application, and, without a reception order or any formality beyond that written application, might be received as a voluntary boarder. The will, the *volunter*, in the case of an unmarried person under 18, was transferred to the parent or guardian. Such procedure was possible now in most licensed houses, and sometimes in single care, but not for the poorer class of the community. The rate-aided mental hospital, which used to be called the pauper lunatic asylum, had no provision for receiving the voluntary boarder. The Royal Commission had before it distressing cases of people who felt they were becoming unstable, and that rest and treatment would set them right. They were unable to receive that treatment from a recognized county asylum until they became so bad that they were certifiable. Another point about the voluntary boarder was that any doctor who took such a person into single care was always liable to prosecution for harbouring an uncertified lunatic. Earl Russell drew attention to Subsection 3 of Clause 1, by which a voluntary boarder must give seventy-two hours' notice before leaving. It would not be in the interest of the patient to allow him to leave at a moment's notice, as the occasion when he insisted on leaving would probably be that when he had become unable to look after himself. This delay was not necessarily imposed in every case, but only where the medical officer thought it necessary. It gave the opportunity for the patient to come back to a better mind, or for the medical officer to proceed, if necessary, to certification.

Clause 2 provided that notice of a patient's reception was to be given within two days to the Board of Control. Notice was also to be given to the Board if he died or departed from the institution. Should the patient become incapable of volition he was not to be kept as a voluntary boarder for more than a month. Before the end of that period he must be discharged unless he again became capable of volition, which often happened, or unless steps had been taken to certify him. The public could rely on the Board of Control to see the patient was not unfairly treated.

Answering a question by the Earl of Onslow, Earl Russell said the period of a month would probably be used to apply to a voluntary boarder who became incapable of volition the provisions of Clause 5—temporary treatment. The real safeguard for every person who was detained or under treatment was the Board of Control, and by the bill the powers of the Board were increased.

Under Clause 3 a Commissioner, not necessarily a member of the Board, but an official visitor, might at any time visit a voluntary boarder and report on the case. The Board might order the superintendent to discharge the patient or to take steps to deal with him, if necessary, as a person of unsound mind. To the Minister of Health these provisions did not seem to leave much opportunity for abuse.

Clause 5 was more contentious. It provided for the temporary boarder, a person suffering from mental disorder, incapable of volition, and likely to benefit by temporary treatment. If an application was properly made and a certificate given, he might be detained six months, a period in which, according to statistics, a large number of recoveries took place. The period was perhaps not so long as would be most useful, but the Minister of Health had been moderate in his estimate. The application must be made by husband, wife, or relative, or if not so made it must state why it was not so made, and what was the interest of the person making it. The patient must then be examined by two doctors, as against the one now required for the ordinary certification of the rate-aided patient. The great difference was that there was no intervention of a justice of the peace. In the view of the Government two doctors provided a greater safeguard than any number of justices of the peace. One of the two doctors was either to be the patient's usual medical attendant or an official person, officially appointed, who could have no improper interest in the matter. The Royal Commission had suggested a rather different procedure by a provisional order, and did introduce the justice of the peace. The Ministry of Health had thrown over the provisional order because, though intended to remove the stigma of certification, it would in a short time be held to be exactly equivalent. The Royal Commission had said that cases wrongfully certified or improperly detained must be of the rarest occurrence. It retained the justice of the peace reluctantly, because it was afraid of Parliament and uninformed public opinion, but added that if free to consider exclusively the medical treatment of the patient it would have little hesitation in accepting certification without the justices. The fear of confinement in asylums, Earl Russell declared, need exist no longer. Rate-aided institutions were full, and the trouble recently had been the other way—sometimes people were discharged almost before they were fit to be at large. The House of Lords should recognize that a doctor was not a sinister figure, anxious to confine a man to a dungeon for life. He treated mental disorder as he treated other disease, with a sole view to its cure. If one of the peers were delirious in a fever he would be without volition within the meaning of this Act for that time. Nobody hesitated in those circumstances to restrain personal liberty in the interest of the patient. The same thing happened in mental treatment. Patients were grateful when they recovered for the treatment they had received. A number of visits might be paid to these patients. The Board of Control was entitled to visit at any time and as often as it liked. The superintendent of the asylum visited his patients regularly. In the rate-aided asylum there was the visiting committee, in the licensed house the visiting justices. The patient's friends were at liberty to visit him. In the case of patients who had property there was the Lord Chancellor's visitor. Subsection 9 of Clause 5 provided that in addition to the Board of Control's visit, within one month the patient was to be visited by two members of the visiting committee or by two of the visitors of licensed houses. After that visit they were to sign a statement that it was or was not proper for the patient to continue to be detained, and must report their opinion within two days to the Board of Control. At any time the Board of Control might order that a person received as a temporary patient should be discharged or dealt with as a person of unsound mind. The public had no reason to fear these provisions. The whole object was to assimilate the treatment of mental disease to the treatment of other disease. The Government looked on the bill as likely to empty the certified wards and to send people back without a stigma.

Clauses 11 to 15 reconstituted the Board of Control in accordance with the views of the Royal Commission. At present there were about twelve Commissioners on the Board, some medical and some legal. They regulated policy and visited institutions. They were so busy running about the country that they never had real consultative meetings in London to decide on the principles to be applied. The bill proposed to divide the Commissioners into two parts. Five would constitute the Board of Control, and would have as their primary duty the co-ordination of all general administration—provision of drugs, qualification of nurses, staffing of asylums, construction of asylums. They would meet regularly and without interruption, and would be called the Senior Commissioners. Other Commissioners and Assistant Commissioners would do the visiting, and Clause 13 provided that one Commissioner might carry out visits at present required to be done by two. The law's requirement that two Commissioners must visit had been impracticable for some time. The Senior Commissioners would from time to time visit institutions to see with their own eyes what was going on. Clause 11 provided that they should be composed of a chairman, a legal Commissioner, a medical Commissioner, and a woman, leaving one place, which might be filled by another medical Commissioner. Existing Commissioners who were not members of the Board of Control would continue as Junior Commissioners, though that title was not in the bill.

Earl Russell said that Clause 6, which required local authorities to provide accommodation for temporary patients, was not likely to increase their total accommodation, and in the end would diminish it. Clause 8 provided for circumstances which had arisen under private Acts, such as for the Maudsley Hospital. He called the attention of the House to Subsection 2 in Clause 16. This was an attempt to provide further protection for the medical men who gave certificates. Recent actions, particularly the Harnett case, had not unnaturally frightened medical men, and they were chary of giving certificates for which they might be shot at, even, as in the Harnett case, twelve years later. It was a very grave responsibility for a professional man to take. It not only cost him money, it might ruin him professionally. After that case there was a great shyness on the part of doctors in giving these certificates in proper cases. No one could blame them for that. They were not paid more than an odd guinea or two, and they were taking a serious risk. The Royal Commission was pressed by the doctors to give them complete immunity. Those on that Commission who were lawyers felt that would be contrary to the principles of

law. The doctors themselves said, when asked: "No, we are not asking, and we do not ask, immunity for a rascal or a rogue, or even for a thoroughly reckless person. But we do say it is a little hard that people who are exercising their profession honestly and to the best of their ability should be shot at in this way."

The EARL OF ONSLOW *asked whether the immunity proposed* would apply to certificates regarding people not capable of volition under Clause 5 of the bill.

Earl RUSSELL said he thought so. Resuming his account of the proceedings of the Commission, he said that body finally recommended the form of words which the House would find as the substituted Subsection (2). The effect of these words was not to give the doctors immunity, but to shift the onus. The bill said:

". . . such proceedings shall . . . be stayed on such terms as to costs and otherwise as the court may think fit, unless the court is satisfied that there is substantial ground for alleging that such act was done in bad faith or without reasonable care."

That would present some difficulty to the judges, but there were statutes containing somewhat similar provisions on which they now and then acted. There was a statute about vexatious actions. *The subsection meant that the plaintiff would have to satisfy the* judge at an early stage that he had a prima facie case, and that there was something which required investigation. This was not by any means a final protection to the doctors—very far from it—but it was some protection from suffering from legal actions when they had done the best they could.

Clause 17 made urgency orders applicable to rate-aided persons. Curiously enough urgency orders were now only applicable to private patients. The rate-aided person could only be, so to speak, taken in charge if he was found wandering or in other circumstances when he was dangerous to himself or to others. This would give the opportunity of making an urgency order in all proper cases. Clause 16 removed the anomaly by which any person taken to a workhouse, certified, and sent to an asylum must remain a pauper even if afterwards found to be a person of means. Clause 19 enabled county councils to use the workhouses which would come into their possession under the new Local Government Act. Clause 20 abolished the use of the terms "asylum" and "pauper lunatic." The change of name implied a change of spirit.

The bill had not made a complete code, nor had it assimilated completely the methods of certification in private and pauper cases, which differed in the Lunacy Act of 1890. Neither had the bill dealt with the vexed question of licensed houses, the only question on which the Royal Commission disagreed. Parliament must some day make up its mind what it was going to do about licensed houses. The licensed house was an institution for the treatment of insanity, run by a doctor or several doctors, or at any rate staffed by a doctor, for private profit. The public was perfectly right, no doubt, in looking with the very gravest suspicion upon places of that kind. When Parliament last dealt with this question, in 1890, it adopted an illogical and indefensible halfway-house attitude. The existing private licensed houses were allowed to go on; no new licensed houses were allowed to be created. No number of beds were allowed to be added to those already in existence in the licensed houses then existing. In effect, Parliament said: "We are not quite sure whether this thing is so bad that it ought to be swept away altogether, but at any rate we are not going to let it be increased." Either a licensed house was a necessary institution serving a beneficent purpose in the case of a private patient who could afford to pay for treatment, or it was an evil that ought to be swept away. In fact, licensed houses were not so geographically distributed as to be convenient. That had nothing to do with this bill.

In conclusion, Earl Russell said he had been through the bill carefully with the chairman of the Royal Commission, who authorized him to say that he welcomed it as a useful instalment of the reforms which the Commission proposed.

Lord Brentford's Criticisms.

Lord BRENTFORD said that, with regard to the question of the liberty of the subject, there was a distinct difference between the disease of insanity, whether mere lack of volition or complete insanity, and every other physical disease. The Act of 1890 showed the meticulous care of Parliament for the liberty of the subject. Its provision that a petition for a reception order must be *presented to a special justice* of the peace was not only a safeguard for the patient, but for the medical men. Earl Russell proposed to take away part of the legal responsibility of medical men and at the same time to take away the one great safeguard both for the medical men and for the patient. The procedure proposed for the young person under 18 should be *most carefully* considered by the House. Without any assent on his or her part a boy or girl of nearly 18 could be placed as a voluntary patient on the written request of the parent or guardian with no doctor's certificate and no judicial authority. Earl Russell had tried to prove too much in regard to the Board of Control. If that safeguard was so great, why trouble about medical certificates and the reception order, which would still be needed for the man who was flagrantly insane. It was remarkable to retain the safeguards for that man but to sweep them away in doubtful cases. Clause 5, dealing with temporary treatment without full certification of persons who had lost volition, would require amendment. "Incapable of volition" was a new expression in an Act of Parliament, and the unanimous recommendation of the Royal Commission, as also of the Mental Treatment Bill introduced by Lord Onslow in 1923, was that there must be a judicial decision. That was the law of the land now, and the Royal Commission had doubted whether public opinion would countenance a departure from it. Lord Brentford said he was anxious to do what he could in transferring the onus of proof from the medical man, under Clause 16. As a lawyer, and as one who had held Ministerial office, he well knew the scandal of certain actions taken against medical men. But if the medical man was to be given this protection the patient must have the protection of a judicial inquiry. He further hoped the Government would accept an amendment to strengthen the medical element in the Board of Control. He also thought that the bill proposed to transfer too many powers from the Minister of Health to the Board of Control, which could not be called to account in the House of Commons. Taken as a whole, the bill would largely improve medical care and treatment, particularly incipient medical treatment of those on the border line; but it was more important for the House to guard the liberty of the subject.

Lord SANDHURST approved the proposal not to connect temporary treatment with judicial or legal proceedings. They should emphasize the medical aspects, and not place the patient in the position of a sort of criminal. He welcomed a provision, which Earl Russell had failed to mention, for the after-care of patients by local authorities, or through after-care associations. After-care was nearly as important as treatment during detention, and not only for poor patients. He would prefer that the absence of volition for a month did not automatically end the status of a voluntary boarder. In Scotland a patient was allowed to retain his position as a voluntary boarder so long as he did not insist on the right to be discharged. [The bill does not apply to Scotland or Northern Ireland.] Lord Sandhurst thought there should be added to the bill a provision allowing the Board of Control to extend the period of temporary treatment for non-volitional patients who showed signs of recovery. He regretted that the bill did not, as recommended by the Royal Commission, allow a medical superintendent to certify that, though a petition had been made for the discharge of a patient, that discharge to the petitioner would be *contrary to the welfare of the patient. He hoped the qualifications* of the Assistant Commissioners would be those provided by the principal Act. Some of the women visitors should have nursing experience. He did not see any great protection to the medical man in the shifting of onus. It was a poor case which could not produce some prima facie evidence throwing the onus upon the medical man.

Lord Dawson Supports the Bill.

Lord DAWSON OF PENN said the bill attempted at long last to adapt legal enactment to informed opinion. It was useless to have a new idea and seek to embody it in legislation unless the House was prepared to take a new view of the methods. For years informed opinion had wanted reform. The object in mental as in bodily disease was early diagnosis and early treatment to prevent more grave maladies arising. The present law was based on the assumption that mental ailment was insanity. There has grown *up, therefore, in the public mind the notion* that any kind of mental disease was associated with some slur, some disability inflicted on the patient and his family. The result was that the friends of that patient unconsciously entered into a conspiracy to prevent mental ailment being handled, for the reason that they knew there was a danger, if it were treated, of the patient being dubbed insane and treated as an insane person. Therefore it was necessary to make the machinery of this bill as new and fresh in its form as the ideas which inspired it. If they left what was thought of as insanity and came down to mental derangement, they would find that that was constantly side by side with physical *derangement. It was often* a matter of chance whether a patient who had been ill suffered from a mental complication or a physical complication. Certain complications followed on typhoid fever. It was a matter of chance whether the patient suffered from a clot on the brain or from some temporary mental derangement. Why should they treat one differently from *the other? They might* have been restraining that patient through delirium, and why should not they apply the same medical treatment to the mental complications as to the bodily complications? With increasing speed and strain of life, in which the material progress was going too far ahead of man's powers of adaptation, they would get a larger number of cases of temporary mental trouble, and find a physical trouble followed by mental symptoms, or mental symptoms followed by physical ailment. Disease, if he might use the expression, bred less and less true. It conformed less and less to type. In these days, when acute infections were gradually being wiped away, the colour and the pattern of disease was more likely to be determined in greater degree by man's make-up, his family history, his environment, the strain he had been liable to meet, and the result was often such conditions of mind as the House

was discussing that day. This bill, in Lord Dawson's opinion, was a considerable advance, which would have the support of the best thought in the medical profession. Technical knowledge had grown. The medicine of to-day was not the medicine of fifty years ago, and had become so technical that Parliament had to trust the people who had studied the form. Medical men now had greater knowledge and greater judgement. A public opinion was rising up in the profession, and grew stronger each year. That public opinion in the profession was the great safeguard to prevent abuse. If Parliament introduced judicial authority wholly unsuited to judge of the merits of the question it would not have the advantage of the voluntary section of the bill. That would not be taken advantage of by the patients, nor would the doctors try to persuade them. Doctors were not going to have skilled opinions overhauled by local magistrates who did not understand the A B C of the profession. Lord Dawson remarked that as he did not want to go to a magistrate to ask if he might restrain delirious patients, he did not want to go to him to restrain a patient suffering from a complication after that illness. Certified insanity was another problem, whether the patient was so disabled that for his own safety, or that of the community, he had to join a cloistered class. They therefore made such an inroad on that patient's liberty, and for such a time that it was necessary to have more control. The question of temporary loss of volition, which occurred even after influenza, should be left to the decision of medical men—two of them if Parliament preferred. If Parliament was to get the full benefit of the part of the bill dealing with volition it would require to distinguish between an automatic refusal, for example, and an intelligent negative. The two clauses dealing with voluntarily boarders and those who had temporarily lost volition if carried out without undue restraints would add to the sum total of the health of the community.

The EARL OF OXFORD asked whether Earl Russell would consider increasing the Board of Control by one and making the additional member a Medical Commissioner.

Lord DAWESTOFT welcomed the bill as an overdue reform, but doubted whether Clause 16 was sufficient to protect doctors who signed certificates or made recommendations. He hoped that in committee Earl Russell would devise some really substantial protection for the doctors.

Lord CRANBROOK hoped the bill was the forerunner of another which would bring all public health services together instead of leaving mental work divided from public health work. He thought the provision in the bill authorizing local authorities to have out-patient clinics was a great step in advance. They would save many people from going into institutions.

Replying to the debate, EARL RUSSELL said he regarded these clinics as a valuable feature. He did not propose to take the committee stage till December 9th, to give adequate time for putting down amendments. He himself was not sure that the protection offered to medical men was substantial, and if the House were prepared to extend it further he might not oppose. He was grieved to hear Lord Brentford talk, at this time of day, about the need for the intervention of justices. Everybody connected with asylum administration knew that the only thing of which the doctors thought was the benefit and health of the patient. The precautions for the liberty of the subject, of which Lord Dawson had spoken, were what spoilt the Act of 1890. In Scotland, where the practice showed an immense advance on English practice, mental patients were treated in a very flexible way, with enormously good results to their health. Intervention by a justice was nowadays in England the merest formality, adding nothing to the safety of the patient.

The bill was then read a second time without a division, and will be taken in committee of the whole House.

Workmen's Compensation (No. 2) Bill.

Mr. GEORGE HIRST moved in the House of Commons, on November 29th, the second reading of the Workmen's Compensation (No. 2) Bill. He said this was introduced to deal with the case of the man who, after meeting with an accident, had been declared by the doctor to be fit for light employment. That man went to whoever employed him and asked for light work. He was refused by that particular employer and, when he walked away, his compensation was stopped or reduced by the judge.

Mr. GRUNDY seconded. He said there was no greater tragedy in unemployment than that of the man who was certified by a medical man to be fit for light employment.

Mr. ATKINSON moved the rejection of the bill, but Mr. CLYNES and Lord EUSTACE PERCY supported its principle, while recognizing that amendments were required. The bill was then read a second time without a division and sent to a committee.

Radium.

Mr GREENWOOD told Sir J. Power on November 28th, that he could not make any statement on the progress of the work of the Radium Commission. The Radium Trust and the Radium Commission were constituted by Royal Charter, which required the Commission in each year to lay before the Trust an annual report of their work, a copy of which must be furnished to the Treasury, for presentation to Parliament.

Women Medical Officers of Prisons.—Mr. Lovat Fraser was informed by Mr. CLYNES, on November 28th, that there were two women medical officers at Holloway Prison. There was also a woman medical officer at the Borstal Institution at Aylesbury. The appointment of a woman medical officer in women's sections of prisons, where the women formed only a small proportion, meant adding to the staff and paying two officers where one could do the work.

Prison Medical Officers and Flogging.—Replying to Mr. Benson, on November 28th, Mr. CLYNES said that if a prison medical officer stopped corporal punishment during its infliction his intervention was final and there was no further flogging. Officers with over thirty years' experience of the prison service had never heard of cases where the use of the cat was stopped in order that the prisoner might recover sufficiently to endure it later.

Inspectors of Vivisection Experiments.—Mr. CLYNES told Mr. Freeman, on November 28th, that there were two inspectors of vivisection experiments, both with medical training. There were no vacancies at present, and no further appointments were contemplated. Candidates with the best qualifications, irrespective of sex, would be appointed in the event of a vacancy. Replying further to Mr. Freeman, who said that the strongest representations had been made to exclude dogs from vivisection, and who asked for more records relating to them, Mr. Clynes said no useful purpose would be served by the publication of figures in addition to those already given in the annual return.

Proposed Whole-time Medical Commissioner in India.—Mr. WEDGWOOD BENN, on December 2nd, told Major Graham Pole that the demand for a grant for the expenses of a European officer of the Indian Medical Service as a whole-time commissioner of medical qualifications and standards had not been rejected by the Indian Legislative Assembly. The House was adjourned before the termination of the debate. The Government of India was consulting the provincial Governments on measures to secure the continued recognition of Indian medical degrees. The creation of the commissionership was proposed as a temporary measure pending the establishment, by legislative enactment, of an All-Indian Medical Council.

The Services.

ARMY MEDICAL SERVICES.

LIEUT.-COLONEL W. P. MACARTHUR, D.S.O., O.B.E., M.D., F.R.C.P.I., R.A.M.C., professor of tropical medicine, Royal Army Medical College, has been appointed consulting physician to the British Army from December 10th, 1929, in succession to Colonel J. C. Kennedy, C.B.E., M.D., K.H.P., who is proceeding to India for duty.

Universities and Colleges.

UNIVERSITY OF OXFORD.

Radcliffe Travelling Fellowship, 1930.

AN examination for a Radcliffe Travelling Fellowship of the annual value of £303, and tenable for two years, will be held at the University Museum, commencing on Tuesday, February 11th, 1930, at 10 a.m.

Candidates must have passed all the examinations required by the University for the B.A. and B.M. degrees. They must not have exceeded four years from the time of passing the last examination required for the degree of Bachelor of Medicine. The successful candidate must, before election, declare that he intends to devote himself during the period of his tenure of the Fellowship to the study of medical science and to travel abroad with a view to that study; the Fellowship will be vacated *ipso facto* if he spends more than nine months in the whole within the United Kingdom. The Regius Professor of Medicine and the examiners pass a yearly report on the work done by each Fellow to the Electors, who may, if they think the report unsatisfactory, declare the Fellowship forfeited. The examination will occupy four days. Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay; there will also be a practical examination in pathology. Any candidate desiring to offer, in addition, a special branch of medicine or surgery must send notice of this to the Regius Professor of Medicine, University Museum, Oxford, on or before January 29th, 1930, by which date the names, addresses, qualifications, etc. of all intending candidates should be in the hands of the Regius Professor.

At a congregation held on November 23rd the following medical degrees were conferred:

D.M.—G. P. Wright.
M.Ch.—C. W. Flemming.
B.M.—J. A. Eyres.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on November 30th the following medical degrees were conferred:

M.D.—R. J. Lythgoe, H. W. Eddison.
M.B., B.Chir.—M. D. Nosworthy, J. M. Graham, E. A. Trim.
M.B.—F. Goldby, J. O. W. Bland.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examination indicated:

DIPLOMA IN PSYCHOLOGICAL MEDICINE (*with special knowledge of Psychiatry*).—P. T. Thorpe, Mary E. Tyars.

Obituary.

LIEUT.-GENERAL SIR ARTHUR SLOGGETT, K.C.B., K.C.M.G., K.C.V.O., F.R.C.S.,

Late Director-General Army Medical Services.

As briefly announced in our last issue Lieut.-General Sir Arthur Thomas Sloggett, K.C.B., late Director-General of the Medical Services of the Army, died suddenly, aged 72, on November 27th, while walking with his son near Regent's Park. He was the son of the late Inspector-General W. H. Sloggett, R.N., and of his wife, Elizabeth, daughter of Thomas Cornish-Crossing, J.P., of Stoke Damerel, Devon, and was born at Stoke Damerel on November 24th, 1857. He was educated at King's College, London, and took the diplomas of M.R.C.S.Eng. and L.R.C.P.Ed. in 1880. Entering the army as surgeon on February 5th, 1881, he attained the rank of colonel in less than twenty-three years, on September 8th, 1903, having had the good fortune to gain special promotion for war service on two occasions. He was specially promoted to surgeon lieutenant-colonel on November 18th, 1896, for his services in the Dongola campaign, and to the higher rate of pay as lieutenant-colonel on October 15th, 1898, for gallantry in the battle of Khartum. As colonel he served as principal medical officer of the London district. On May 13th, 1908, he was promoted to surgeon-general, and went to India as principal medical officer of Bombay, the 6th Division. On December 21st, 1911, he was appointed principal medical officer at headquarters in India, and Director of Medical Services in India; and on June 1st, 1914, was appointed Director-General of the Army Medical Services, with the rank of lieutenant-general, succeeding Sir Launcelotte Gubbins in that post.

During the thirty-three years he had served in the army before becoming Director-General, he had seen a great deal of active service. In the Dongola campaign of 1896 he served as senior medical officer of British troops, was mentioned in dispatches in the *London Gazette* of November 3rd, 1896, and was promoted to surgeon lieutenant-colonel, and received the Egyptian medal with a clasp, and the fourth class of the Osmanieh. In the Nile campaign of 1898 he served as senior medical officer of the 1st Brigade, British Division, and took part in the battle of Khartum, where he was dangerously wounded, and had his horse shot under him. He was himself shot through the chest by a bullet, which apparently should have pierced his heart, and used to account for his not being killed on the spot by saying that his heart must have been in his mouth at the time. For his services in the Nile campaign he was mentioned in dispatches in the *London Gazette* of September 30th, 1898, and was specially promoted to the higher rate of pay as lieutenant-colonel, and received the medal for the campaign, a clasp to the Egyptian medal, and the third class of the Medjidieh. He then served in the South African war from 1899 to 1902, first in charge of the Imperial Yeomanry hospital, afterwards as principal medical officer of a general hospital, and as commandant of Deelfontein district. He took part in operations in the Transvaal, the Orange River Colony, and Cape Colony, was mentioned in dispatches in the *London Gazette* of April 18th, 1901, and received the Queen's medal with three clasps, the King's medal with two clasps, and the C.M.G.

Two months after his appointment as Director-General the great war of 1914-18 began, and a month later he went to France as Director-General of the Medical Services of the British Armies in the field, and as Chief Commissioner of the British Red Cross, and of the Order of St. John of Jerusalem. It was, of course, quite beyond the power of one man to fill these posts and at the same time carry on what might be called the ordinary work of Director-General. So, while Sloggett remained on active service, Sir Alfred Keogh rejoined the services from retirement to carry on the duties at home. In France Sloggett remained for nearly four years, until in June, 1918, his four years' term of office as Director-General came to an end. Many were of the time of opinion that he should have been specially retained in the post he had filled so well until the war came to an end; the authorities, however, decided otherwise, and he was placed on the retired list from June 1st, 1918. For his services during the war he was mentioned in dispatches seven times, in the *London Gazette* of February 17th, 1915, July 10th, 1915, January 4th, 1917, May 29th, 1917, December 24th, 1917, May 25th, 1918, and October 21st, 1918; and received the K.C.B. in 1915, the Legion of Honour, Grand Officer (2nd class), in 1915, the Order of King Leopold of Belgium, Commander (3rd class), in 1916, the K.C.M.G. and K.C.V.O. in 1917. Besides these honours he had been appointed a Knight of Grace of the Order of St. John of Jerusalem in 1898, he received the C.B. in 1910, and in 1917 was elected a Fellow of the Royal College of Surgeons of England.

Sir Arthur Sloggett was a great administrator, as his work shows. He had the qualities of tact, tolerance of other people's opinions, and good capacity for business. Not only could he see things from another man's point of view, but he could induce other men to see them from the point of view of others, as well as their own. In the war he had serving under him a large number of men of great reputation in their profession in civil life, all entitled to consider themselves leaders and experts in their own line; most of them quite ignorant, to start with, of military routine and military duties, but all anxious to do their best to help their country in its time of need. By his tact and capacity he got the best work out of all his staff, and made the medical services of the army work as one harmonious whole. When he laid down his office he addressed to the Hon. Sir Arthur Stanley, chairman of the Joint War Committee of the British Red Cross and the Order of St. John, a letter in which he characteristically gave all the credit for the successful running of the medical services in the war to those who had served under him.

In 1881 he married Helen, daughter of Mr. J. R. Boyson, formerly Solicitor-General of Madras, and had one son, Lieut.-Colonel A. J. H. Sloggett, D.S.O., late Rifle Brigade, and two daughters.

The funeral service was held in the chapel of the Queen Alexandra Military Hospital, Millbank, on December 2nd. The King was represented by Lieut.-General H. B. Fawcett, Director-General of Medical Services, the Duke of Connaught by Major-General Blackwell, and the Army Council by General Sir Walter Braithwaite, Adjutant-General to the Forces, and Sir Herbert Creedy, permanent Under Secretary of State for War. The interment afterwards took place at St. Peter's Church, Petersham.

We are indebted to Sir GEORGE MAKINS, G.C.M.G., Past-President of the Royal College of Surgeons of England, for *the following appreciation:*

Sir Arthur Sloggett's distinguished career in the medical services of the army will no doubt receive adequate notice in your columns, but a note embodying the impressions of a civilian surgeon who witnessed the part he took in the great war may not be out of place.

The early months were unfortunate for Sloggett in that after being responsible for the exacting duties concerned with the mobilization, he fell ill, and after a short interregnum Sir Alfred Keogh was recalled to take his place. When he had recovered, the somewhat hazardous experiment was decided upon of establishing a Director-General at the War Office and a Director-General Overseas, and it says much for the character of both these officers that the arrangement worked excellently well for the next three years. Sloggett was appointed to the latter post, and was sent to France, where he had to create and consolidate a novel position, a matter calling for tact and ripe judgement. The task was speedily accomplished, and it may well be that his new post was really better suited to his special capabilities than that at the War Office in London.

His success in the field, I think, depended mainly on two qualities: (*a*) his unusual capacity for drawing men together and inciting them to work harmoniously, and (*b*) the breadth of view with which he regarded proposals that might be made to him. In developing these two theses I would first dwell upon his shrewd judgement and knowledge of men; this aided him in the choice of his personal staff: each member was selected on account of special fitness, even including one who by his instinctive sense of regulations was competent on occasions to modify the somewhat generous promises made by his chief. He treated the members of his staff as personal friends, and I think no one could have been better served. He drew no distinction between civilian consultants or Territorial officers and those of the regular service; from either he was open to receive suggestions, and he made the best of the opportunities thus afforded. An effective liaison was developed between the British and Allied medical services which was of value in creating mutual respect and friendship. Lastly, from this point of view, the relations which he maintained with the various voluntary associations must be mentioned. He acted as the representative of the British Red Cross Society and of the Order of St. John of Jerusalem, and was accustomed to refer to the conjunction of these two bodies with the medical service as a "trinity." He was liberal in his dealings with the various voluntary hospitals, and there can be no doubt that as a consequence of the attitude he took up the British soldier got the greatest advantage he could from these sources.

Sloggett's breadth of view had far-reaching influence on the strictly professional work of the medical service. He was not bound by tradition or pride in the corps, but was keen and ready to receive suggestions from each and all. His common remark was "Let every man have his chance," and in consequence many valuable suggestions bore fruit. Not a little of the advance made in front line treatment, the special arrangements made for cranial and abdominal wounds, fractures, and burns were made possible by the facilities readily provided by the Director-General. Again, the same may be said of the various research units established, and in all these matters he was actively supported by his colleague Sir Alfred Keogh at the War Office.

Finally, I would like to add the testimony of an old friend to his delightful hospitality. All who had occasion to visit his headquarters were met with his genial smile and treated to the best he had to give. This genial reception, moreover, was not confined to the manners of the chief; his precept and example were adopted by every member of his staff, and many of us retain the happiest memories of our visits.

Lieut.-General Sir CHARLES BURTCHAELL, K.C.B., who succeeded Sir Arthur Sloggett as D.G.M.S. British Armies in France, writes:

Sir Arthur Sloggett was unquestionably the most remarkable and the best known of a small group of distinguished men who were the outcrop of some 109 officers commissioned in the year 1881 into what afterwards became the Royal Army Medical Corps, and who, having taken part in all British campaigns since 1882, came to hold positions of high importance and responsibility during the great war. Such were, to mention but a few, Major-Generals W. Babtie, T. P. Woodhouse, T. J. O'Donnell, M. W. O'Keeffe, R. H. S. Sawyer, R. Porter, W. G. A. Bedford, and W. G. Birrell. Arthur Sloggett conformed to no type in character or temperament, and those who knew him best and understood the soul within the man will no doubt agree with me, who was his intimate assistant for many years, and his fast friend up to the end, that they never met any other man quite like him in any sphere of life. But, lest there should be a wrong impression of what we, who were in close touch with him, thought, let me say at once we loved him and served him loyally and cheerfully. Why? Because we knew that behind all his actions and thoughts was a good nature of unusual stability, a genuinely kind heart, and an earnest desire to help in any possible way to bring happiness to his fellow men, and that he never bent to crooked ways. His gay vitality was infectious and created an atmosphere of happiness for his immediate entourage in France. But long before he came prominently before the public eye as Director of Medical Services of the British Armies fighting in that country, he had done much to earn the esteem, gratitude, and affection of the Royal Army Medical Corps as an administrator in London, Poona, and of His Majesty's Forces in India. He ever had the advancement of the work of the corps at heart, and was unfailing in his efforts to promote contentment among those serving under him. He was instrumental in bringing together in India some of the best athletic teams which the corps produced.

He was a remarkably shrewd judge of men and of the vagaries of human nature. His power as a peacemaker was unique among men in his position. Should a cloud of dissension arise among any set of people of any station in any part of the vast machine under his direction, it was dissipated quicker than it came through his tact and kindly bright manner and shrewd common sense, which he administered with a resourcefulness quite outside the capacity of most men. If a disagreeable thing had to be done it was accomplished in such kindly settings that as a rule no unpleasant taste was left, and, generally speaking, the victim emerged with a feeling that he could not have been better treated. Of course, in the position Sloggett occupied he would not have been human if he did not occasionally commit an error of judgement or allow his exuberant spirits to carry him over the borderline which some people marked out as the limit of circumspect discretion. Still, his errors were very few and very trivial, and his lapses quite harmless, and laughable, and in their sum total counted as nothing compared with the high and progressive standard of efficiency he maintained through the influence of his personality over all those who were in control of this or that in the multitude of sectors which made up the organizations for the relief of the human sufferings brought about by the war.

His part in working up into friendly co-operation the functions of the medical elements of the Regular Army with those of the British Red Cross Society and the Order of St. John, and creating a single harmonious body out of the consultants of various grades, is well known. Supposing we put the question to those in the best position to know: "Would the lamentable amount of suffering endured by the gallant men who held the line in France throughout those three and a half years of war have been less had someone other than Sir Arthur Sloggett directed the medical services?" The answer will undoubtedly be, "*No*, and it might have been more." His breezy cheerfulness lasted up to his retirement from France. The time between the date of the War Office notification and his departure was about five days, during which the medical services were brought nearest to a point of failure ever reached. The best part of five British Divisions operating with the French had been driven out of their positions and thousands of British soldiers were scattered through French army hospitals even as far south as Biarritz. The 20,000 beds at the Etaples base had been put out of action by enemy bombers, who destroyed the railway. Sir Arthur

this period packed up and left, saying, "Well, dear, old boy, I hand over to you. Good luck."

After the war Sir Arthur held the appointment of Colonel Commandant R.A.M.C. for several years, and up to his death he was, as always, in close touch with everything of interest to the corps he loved so well. Only a few weeks ago he said to me, "I may go out any day, but never mind, I have had a good life." He thus looked to the end of this earthly sojourn with the cheerful courage which carried him so usefully and gallantly through life. We are glad he died in the way he expected and wished to die, without pain or suffering, and we say "Vale" with an affection and remembrance that cannot be effaced.

Lieut.-Colonel A. E. J. LISTER, I.M.S. (ret.), sometime surgeon to H.E. the Commander-in-Chief in India, writes:

Many will write of Sir Arthur Sloggett's brilliant achievements. May I just pay a personal tribute as showing his relations with his junior officers? I was his medical attendant in Simla for some slight ailments, and saw a good deal of him in 1912-13. Though I was a junior captain and he was the Director of Medical Services, he was quite one of the most considerate of my patients. He knew the life of a staff surgeon was at times difficult, in the hills. For a slight service, a little beyond the actual scope of my duties, for which some men in his position would have barely thanked me, he gave me a handsome piece of plate. This was typical of the man. It was his kindly consideration which endeared him to his juniors. He never made one feel one was under his orders. He was indeed what we called in India a "pucca Sahib" to work under.

LAURENCE BALL, M.D., F.R.C.P.,

Joint Professor of Medicine in Birmingham University, and Physician to the Queen's Hospital.

WE regret to announce that Professor Laurence Ball died at his consulting rooms in Newhall Street, Birmingham, on Wednesday, November 20th. He had previously appeared to be in his usual health, and his death came unexpectedly and with tragic swiftness.

Laurence Ball was born in Birmingham in 1884, and was the only son of an architect in that city. He received his medical education in the Birmingham Medical School, and graduated M.B., B.S.Lond. in 1907; four years later he obtained the diploma L.R.C.P., and in 1921 he proceeded M.D.Lond., winning the University gold medal. In May, 1923, he was elected a Fellow of the Royal College of Physicians of London. His resident appointments included: house-physician and house-surgeon at the Birmingham and Midland Hospital for Sick Children; house-physician at the Queen's Hospital for one year; and resident medical officer at the Birmingham General Hospital for one year. After holding these he undertook post-graduate study in London. His first honorary appointment brought him to the staff of the Queen's Hospital as pathologist and assistant physician; he became honorary physician to the same hospital in 1926, the year in which he was appointed joint professor of medicine in the University of Birmingham, after having held for several years a lectureship in pathology.

His interests and activities were wide and varied. He maintained his early interest in pathology, and was a member of the Pathological Society of Great Britain. The legal aspect of medicine also occupied much of his thought, and he was a member of the Medico-Legal Society. He was a member of the Association of Physicians of Great Britain and Ireland. His service during the war took him to France and Italy, and covered almost the whole period of the conflict. He gained the Military Cross, and was mentioned in dispatches by General Sir H. C. O. Plumer for gallantry in the field while serving with the Midland Casualty Clearing Station.

Laurence Ball was a cultured and travelled man, with a keen and discriminating artistic sense which guided him in letters, in music, and in a lively appreciation of the best in art and architecture. A large company, representing all sections of the University and his medical colleagues, assembled at the funeral to honour his passing.

Sir CHARLES GRANT ROBERTSON, Vice-Chancellor of the University of Birmingham, writes:

Laurence Ball was essentially a son of the city of Birmingham and of its University and Medical School. I first came into close personal touch with him some five years ago in two ways—as a member of the board of management of the Queen's Hospital, and in connexion with the big scheme, now, I hope, approaching fruition, for a new teaching hospital and the reorganization of our Medical School, in which I was both officially and personally deeply interested. Shortly after that he was appointed one of our joint professors of medicine—at a considerably earlier age than usual—but the appointment was a proof of the position which he had already won for himself, despite his great modesty. I cannot, of course, speak with any specialist knowledge of his professional skill and clinical ability; but for us laymen, both at the Queen's Hospital and in the University, it was clear that all who were best qualified to judge regarded his future in his profession as already assured. Ball threw himself with a fine loyalty into all his professorial work. Again I cannot speak from direct knowledge; but I have every reason to know that he was an able and inspiring teacher, and very popular with the students in his faculty. He served on the University Library Committee, and was a great help in every way: and I had many occasions to discuss with him large issues of policy in connexion with the new hospital scheme and the Medical School, to which he brought a deep interest in the development of medical science, a wide clinical outlook, and a real grip of principles. He had a high sense of duty, and always conveyed—without ever mentioning it—his recognition of what was incumbent on him, not merely as a professor of medicine, but as an officer of the University. I regard his premature death as a very heavy blow to medical science and our Medical School, for he had just reached the age when for the next fifteen years or so he would have been able to give us of his best—and it would be his best that he would always have given. Naturally shy and retiring, he opened out wonderfully when you came to know him, and the better I knew him the more I was impressed with his knowledge, his judgement, and the real charm of character that underlay his modesty.

Mr. A. W. NUTHALL writes:

Ball joined up early in August, 1914, and went to France with the South Midland Casualty Clearing Station in April, 1915, being stationed at Hazebrouck, Amiens, and somewhere near Corbie until the middle of 1916, when, at his own request, he joined a battalion as regimental medical officer and went to Italy. He served for the full duration of the war. His professional interests were aroused and his outstanding ability exerted to its utmost by the problems presented by war conditions. The effects of chlorine gas (April, 1915) he investigated with the utmost thoroughness; the psycho-neurological symptoms of shock and fatigue, chest wounds, trench fever, were all matters of deep concern to him professionally. He found time to do necropsies under the most awkward conditions, and to keep notes on his cases. To his colleagues he was most helpful both in advice and practice (when he fell to and did a bit of surgery or gave anaesthetics). That he carried out his regimental duties with equal success was recognized by the award of the M.C. in Italy. But to those who knew Ball under war conditions the memory is not of the student, but of the personality of the man. Steady and unperturbed, with a sense of humour that met occasions of formality and of stress alike, a capacity to make the best of, and add spice to, any situation, Ball displayed, in company with his intimates, a side to his character in keeping with his red hair and twinkling blue eyes. He brightened the war for many of us, and, in the words of the senior service, pulled his weight and was a good messmate.

Dr. J. G. EMANUEL writes:

The sudden and untimely death of Laurence Ball is an irreparable loss to the Birmingham Medical School. Young as he was, his profound knowledge and mature judgement caused him to be much sought after both by the medical and the legal profession. In times of sickness his medical

colleagues always turned to him, and he never failed to respond. A most successful teacher, his ideas were clear, his exposition of them lucid. Students thronged to his ward classes and out-patient clinics—and students are severe critics. There was always much competition for the post of his house-physician at the Queen's Hospital. He possessed the rare gift of being able to impart to others the knowledge he had acquired from practice and wide reading, and it was an intellectual treat to hear him present an unusual case. He was a quiet and unostentatious man, but had a most attractive personality and a great capacity for friendship. At committee meetings he said little, but when he spoke his words carried weight. He was a devoted son, and the death of his mother less than twelve months ago left its mark upon him. Cut off at the early age of 45, in the midst of a successful career, his death leaves a gap it will be difficult to fill.

DR. T. L. HARDY writes:

May I add my tribute to the memory of Laurence Ball, whose untimely death has removed from the ranks of the profession a sound physician and teacher of medicine, and a most lovable personality. I have enjoyed the privilege of his friendship for ten years, time enough to appreciate his many sterling qualities, for he combined in rare measure great modesty, charm of manner, and a love of the beautiful things in life and no less of its simple pleasures. He had a great capacity for friendship, a generous tolerance of the shortcomings of others, and he spoke ill of no man. Ball was a man of retiring disposition, rarely obtruding his opinions, but never failing those—and they were many—who sought them. It is not many years since, unknown to his friends, he sat for the final London M.D. He confessed later, after having won the gold medal, that he had entered with some misgivings as to how he would fare after so many years of unfamiliarity with the ordeal of examination. He had a great sense of humour, and his laughter was of a most infectious type. He undoubtedly enjoyed life to the full, loving especially the big open spaces, and was never so content as when tramping among the hills of Cumberland or Wales with his friends. On such holidays his companionship was a thing of delight, for he was a man of wide culture, and could talk with learning on many topics. He was, too, an amateur photographer of distinction, and his keen sense of beauty resulted in work of very high artistic merit. With children he possessed something akin to genius, and the joy his company brought to many families is a thing not easily forgotten. Ball contributed but little to medical literature and to research, holding the view that these things interfered with the proper discharge of his teaching duties, to which his energies were mainly devoted during his all-too-brief span of life. As a teacher he was outstanding, whether in the lecture theatre, at the bedside, or in the post-mortem room, while his presentation of a case at a medical society was a model of lucid exposition. He was no specialist—indeed, he heartily disliked the term—but he possessed a wide knowledge of medicine in all its branches, knowledge which had been built up during many years in the post-mortem room. He was in the fullest sense of the term a general physician, with a maturity of judgement remarkable for one of his years.

ARTHUR TEMPLER DAVIES, M.D., F.R.C.P.,

Consulting Physician, Royal Hospital for Diseases of the Chest, and the Metropolitan Hospital.

DR. ARTHUR TEMPLER DAVIES, whose death occurred on November 24th, at his home at Welwyn, Herts, was born in London in 1858. He was the second son of Herbert Davies, M.D., F.R.C.P., a physician long attached to the staff of the London Hospital. Educated at Charterhouse, of which school he was a Natural Science Exhibitioner, he proceeded to Trinity College, Cambridge, where he graduated in 1880, obtaining a second class in the Natural Science Tripos of that year. After leaving Cambridge he went to St. Bartholomew's Hospital, and in 1894 became M.B. of his university. He then filled the positions of house-physician and casualty physician at the hospital. On the termination of these appointments Dr. Davies, following in his father's footsteps, began practice in the City, in his father's house, 23, Finsbury Square. In 1891 he was created M.D. of Cambridge University, and became a Fellow of the Royal College of Physicians in 1894.

The whole of his professional life was spent in the City, and at an early date he was successful in obtaining the important post of physician to the Bank of England, a position his father had held before him. He soon became known as a sound physician, and held a large number of valuable City appointments, of which physician to the North British and Mercantile Assurance Company, the Northern Assurance Company, the Metropolitan Life Assurance Society, and the Westminster Bank may be mentioned. These appointments brought Davies into touch with many sides of City life, and besides his insurance and bank work he enjoyed a considerable private practice. In addition to these activities he was physician to the Royal Hospital for Diseases of the Chest, the Metropolitan Hospital, and the Royal Hospital for Consumption at Ventnor. All of these hospitals he served with diligence and skill, and until he died was connected with all three, either as consulting physician or senior physician. In earlier days he was a regular attendant at the meetings of the Hunterian Society, the Aesculapian Society, and the Society of Life Assurance Medical Officers. In all of these societies he worthily filled the presidential chair. His contributions to the medical press were not numerous, but he edited his father's *Mechanism of the Circulation of the Blood through Organically Diseased Heart*, and published his Hunterian Oration, under the title "Organo-therapeutics—ancient and modern."

The family of Dr. Arthur Davies occupies an interesting position in the history of our profession, and forms an instance of medical appointments being handed down from father to son. In this case Dr. Thomas Davies, the grandfather, began practice in New Broad Street in the early years of the nineteenth century, and was physician to the Royal Hospital for Diseases of the Chest. In time his son, Dr. Herbert Davies, succeeded to the same position, and after him his son, the subject of this memoir, followed and became physician to the hospital. Thus for more than a hundred years the Royal Hospital was served by a member of the family of Davies. They were all also Fellows of the Royal College of Physicians. Dr. Thomas Davies had studied under the great Laennec, and was responsible more than anyone else for introducing into this country the principles of auscultation and percussion. He lectured upon these subjects at his house, and large numbers of the profession crowded to hear his discourse.

The busy life of Arthur Davies has now closed, and he leaves behind him a memory of high purpose and kindliness of heart which brought him many friends and no enemy, and his sound judgement will be missed by all those corporations and companies for which he acted as medical adviser.

A. C.

The following well-known foreign medical men have recently died: Professor FELIX DE SZONTAGH, director of the children's clinic of the Stefan-Tisza University at Debreczen, aged 70; Geheimrat Dr. ERNST GRAEFE, formerly head of the surgical clinic at Erlangen for many years; Dr. FRITZ SEYDEL, a leading Breslau ophthalmologist, aged 60; Dr. VICTOR CHAPPET, honorary physician to the Lyons hospitals, aged 78; Dr. FERNAND DURODIÉ formerly president of the Société de Médecine et de Chirurgie of Bordeaux, aged 82; Dr. SPINELLI, a Naples gynaecologist; Dr. VICTOR RUNOW, an eminent physician of Copenhagen, aged 58, of cerebral haemorrhage; Dr. JAIME FERRAN, a Spanish bacteriologist, who introduced a prophylactic vaccine against tuberculosis, aged 77; Dr. AMICO BIGNAMI of Rome, where he was professor of general pathology, and for many years senior physician to the United Hospitals; Dr. KARL VON DEN STEINEN of Berlin, professor of folklore, and formerly a psychiatrist, aged 74; and Dr. GABRIEL BILLARD, professor of physiology at the medical school at Clermont-Ferrand, of pneumococcal meningitis, aged 56.

Medical News.

THE winter dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, December 13th, at 7.45 for 8 p.m. Mr. F. F. Muecke will preside. Sir James Parr, High Commissioner for New Zealand, will be present as the official guest of the association. All medical visitors from Australia and New Zealand, whether members of the association or not, are invited to be present. The honorary secretaries are Mr. E. T. C. Milligan and Mr. Philip J. Jory, 6, Queen Anne Street, W. 1 (Langham 1579).

AN evening meeting of the British Institute of Philosophical Studies will be held at the Royal Society of Arts, 18, John Street, Adelphi, W.C., on Tuesday, December 10th, at 8.15 p.m., when Mr. G. Lowes Dickinson will lecture on "The value of art." Admission is by ticket, which may be obtained from the Director of Studies of the Institute, 88, Kingsway, W.C.2.

THE twentieth annual exhibition of electrical, optical, and other physical apparatus will be held by the Physical Society and the Optical Society on January 7th, 8th, and 9th, 1930, at the Imperial College of Science and Technology, South Kensington. As on previous occasions, there will be a trade section and a research and experimental section.

UNDER the auspices of the Fellowship of Medicine a lecture on inflammations of the external ear will be given by Mr. John O'Malley, on Monday, December 9th, at 5 p.m., at the Medical Society's lecture hall, 11, Chandos Street, Cavendish Square. On December 11th, at 2.30 p.m., Miss Huxley will hold a clinical demonstration at the South London Hospital for Women, 103, South Side, S.W.4, for women graduates only; at 6 p.m., on the same day, Dr. T. F. Cotton will give a demonstration at the National Hospital for Diseases of the Heart. No fees are chargeable for the lecture or either demonstration. There is still a week left of the two last special courses arranged by the Fellowship for this year; these are the afternoon course at the Infants Hospital, under the direction of Dr. Eric Pritchard, and the course for general practitioners at the London Temperance Hospital each afternoon from 4 to 5.45 p.m. In addition to the special courses, the Fellowship of Medicine arranges a general course, which consists of the clinical practice of its associated hospitals. A programme is provided with the clinics arranged under subject headings, and holders of the comprehensive tickets issued from one week to one year are free to make out their own time-table in accordance with their requirements. This course is continuous throughout the year. Syllabuses of all courses, including the list for 1930, are obtainable from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE annual British Serbian reunion dinner was held in London on November 30th, when the chair was taken by Mr. P. H. Mitchiner, F.R.C.S., president of the Serbian Units Branch of the British Legion, and among those present were the Minister for Jugoslavia in London (M. Georges Diouritch), Sir James and Lady Berry, Dr. Alice M. Hutchison, and others to the number of about a hundred. M. Diouritch expressed his pleasure at addressing this gathering for the fourth time. The occasion recalled the time, fifteen years ago, when Serbia lacked everything; although assistance was forthcoming from various countries, the most appreciated of all was that which was combined, as was the help from Great Britain, with personal service. Scottish women had completed in Dr. Katherine McPhail's children's hospital at Belgrade a memorial in the shape of certain cots to Dr. Elsie Inglis, and the speaker might be further extended by other cots in what was the erbia. Lieut.-Colonel Kidd, R.A.M.C., described a recent visit to Serbia and the grateful friendliness with which he was received; Serbian traditions had not been broken, but had been strengthened, by the experiences of the war. Mr. Mitchiner added other recollections, and the proceedings closed with the singing of the British and the Jugoslav national anthems.

THE council of the Royal Institute of Public Health has made the following appointments as Harben lecturers: 1930. Professor William H. Park, M.D., LL.D., Sc.D., director, bureau of laboratories, Health Department, New York City. 1931. Dame Louise McIlroy, D.B.E., M.D., D.Sc., professor of obstetrics and gynaecology, University of London, Royal Free Hospital. The council has made the Smith Award for 1930 to Dr. H. R. Kenwood, C.M.G., emeritus professor of hygiene in the University of London.

ON his retirement from the post of medical officer of health for the Weston-super-Mare urban district, after eighteen years' service, Dr. John Wallace has been presented with an inscribed silver salver on behalf of the members and officers. The presentation was made by the chairman of the council.

DURING the period 1928-29, the Manchester, Salford and District Mothers' Clinic, which has been in existence for three years, gave advice on contraception to 271 new applicants, bringing the total, since the opening, up to 1,028. The 271 applicants between them had already had 1,015 pregnancies, of which 102 ended in abortion or miscarriage and 38 in stillbirth. Of the 873 children born alive, 67 died under one year, representing an infant mortality of 76.7 per 1,000 live births. Reckoning mortality rates on the basis of the proportion of total deaths (including abortions, stillbirths, etc.) to total pregnancies, the figures for this series are 207 in 1,013, or 204.3 per 1,000 pregnancies.

MR. ROBERT MOND has given £25,000 to the extension fund of the Infants Hospital, Vincent Square, Westminster, payable over the next seven years. This benefaction brings the total amount given or promised to the extension fund to over £100,000.

THE late Lord Forteviot of Dupplin Castle, Perthshire, has bequeathed a legacy of £10,000 to the Perth Infirmary, to be retained intact as an endowment capital sum, so that the income thereof may be applied for the maintenance of the maternity ward.

DR. R. A. LYSTER, formerly medical officer of health to the Hampshire County Council, has been elected a member of Bournemouth Borough Council.

THE second International paediatric congress will be held at Stockholm from August 17th to 20th, 1930, under the presidency of Professor Jundell.

THE Riberi prize of 20,000 lire is offered by the Royal Academy of Medicine of Turin for the best work on a medical subject submitted before December 31st, 1930. The work, which must be printed or typewritten, may be in Italian, Latin, French, English, or German.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

CHRONIC URTICARIA.

"X. Y." (Belfast) wishes to hear of any effectual treatment in a case of chronic urticaria, for which no cause can be assigned.

TREATMENT OF LONG-STANDING EPILEPSY AT THE MENOPAUSE.

"S. O." asks for advice in treating a bipara, aged 47, who has suffered from both grand mal and petit mal since she was 15. The major fits occur in the early morning and at the menstrual period. The minor fits occur between the menstrual flow, and may be as frequent as 300 a day. Though her periods are now very irregular, since she is at the "change," yet the greater fits still occur at the time when, in the ordinary way, the menstrual flow would have taken place. She cannot take bromide, but luminal sodium does to some extent control the grand mal, though far from completely.

STIMULATION OF BREAST SECRETION.

DR. BLANCHE HENDELSON (West Hartlepool) writes: In reply to Dr. L. L. Steele (November 30th, p. 1040), I would suggest that the patient should not be given stout. She should have quiet sleep in the afternoon and at night, undisturbed by the crying of the baby or the snoring of others. She should have only a moderate diet, not a generous one. Fruit and plenty of water are essential, and a sufficient daily motion of the bowel should be secured, but salts or salines should not be used for this purpose. She should wear well-fitting shoes and not be on her feet all day. Skilled massage of the breasts is of great importance. Other instructions may be found in Sir Truby King's manual on *Feeding and Care of Baby* (2s.). Ante-natal treatment is necessary to ensure a good supply of breast milk; it can, however, be increased, or even re-started after cessation of lactation, by such means as the above.

DR. BARBARA J. HICK (Bridlington) writes: The most efficient stimulus for milk secretion is a ring poultice of linseed, with a little mustard mixed in, placed over the breast, but avoiding the nipple.

PROLONGED ADMINISTRATION OF THYROID.

"E. R. G." asks for information about the effect on the heart of taking thyroid in small doses over a long period, and for suggestions which may help him in the treatment of the following case. For some twenty years his patient, while living abroad, had taken thyroid for the treatment of obesity. Her pulse is at times irregular, though not always, its rate being about 90 a minute, and her systolic blood pressure is 150. The heart is a little dilated, and the second sound is accentuated in the aortic area; there are no murmurs. Auscultation of the lungs has revealed moist sounds at the right base, but none at the left. The patient feels oppression and discomfort when she crosses her arms in front or leans forward, and on slight exertion she feels faint and exhausted. She is not taking thyroid now.

LETTERS, NOTES, ETC.

ROSS AWARD FUND.

SIR JAMES BARR informs us that an important donation of £2,000 has just been made to the Ross Award Fund by the Government of India. This generous gift from India brought the total amount of the fund up to £12,682 on November 27th. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

THE SPINE OF GIDEON MANTELL.

IN the leading article in our issue of November 23rd (p. 969) on "Treatment of Scoliosis" it was suggested that the original specimen of Gideon Mantell's spine might be in the museum of St. Thomas's Hospital. This is erroneous. We are kindly informed by Mr. W. E. Thompson, the museum clerk of the Royal College of Surgeons of England, that the specimen is in the museum of the College in the Series of Acquired Deformities, No. 4808.1.

PREVENTION OF SCOLIOSIS.

DR. M. DOUGLAS (Bolton) writes: May I be permitted to express the opinion that no consideration of scoliosis can be complete which does not take into view the important work of Mr. F. Matthias Alexander on the constructive conscious control of the individual? It is true that his methods primarily have nothing to do with the treatment of scoliosis, but it is true also that, as the result of the application of his principle, scoliosis is eradicated and could be prevented. The importance of his discovery of defective sensory appreciation reveals itself no more plainly elsewhere than in that appearance to which we give the name scoliosis, and which is not always a distinctly pathological condition, but often a means whereby the normal accomplish some or other of their daily tasks. Were children trained in the application of Mr. Alexander's principle there would be no need for the treatment of scoliosis, for as scoliosis is an incident in automatic learning through a defective sensory appreciation, with a reliable sensory appreciation and conscious learning on a general basis no such incident could occur.

THE CANCER PROBLEM.

IN the course of a communication relating to Mr. Mansell-Moullin's letter on the cancer problem (November 16th, p. 931), DR. A. T. BRAND writes: To my mind the problem is—When does the medical profession intend to accept the fact that it has long since been established, proved to demonstration that cancer is due to an extrinsic pathogenic micro-organism. Two eminent British pathologists have been successful in isolating a bacterium from every species of malignant neoplasm. Pure cultures have been made and injected into lower animals with the invariable result of forming malignant tumours in these, from which the bacterium has been recovered, thus fulfilling the law of Koch. Mr. Mansell-Moullin states that no surgeon has ever been known to become infected in the course of operations on cancer; but at least three such cases of infection received during operation on cancerous growths by earlier surgeons have been reported. Mr. Mansell-Moullin appears to believe that there is something distinctive about the cancer cell. As a matter of fact, cancer cells are indistinguishable from normal cells, and the microscopist can only diagnose a tumour as malignant from the peculiar manner in which it is related to its environment, apart, of course, from the detection of the presence of the intracellular micro-organism. It is futile to suggest that chemical or any other kind of physical irritation whatever can possibly give rise to a specific disease like cancer, any more than cold and wet can cause pneumonia or a shaving brush cause anthrax. It is a fact that cancer cannot and does not attack the perfectly healthy individual. There must be an antecedent condition of vulnerability to the attack of the causal microbe, which may be induced by every variety of irritation, by obsolescence of organs, senescence, senility, chronic disease, etc. The role of irritation, etc., is one purely of predisposition: the disease appears *post* and not *propter* the action of these inciting agents.

THE ROYAL COLLEGE OF SURGEONS AND ITS MEMBERS.

DR. RICKARD W. LLOYD (London, W.) writes: In your issue of November 30th (p. 1035) I am represented as having said at the annual meeting of Fellows and Members of the Royal College of Surgeons of England that "there had been occasions in the past when the enthusiasm for this resolution was so great that the gates of the College had to be closed against the press of Members." As that does not correctly express my remarks, may I be allowed to say that it having been said at the meeting that little enthusiasm seemed to be associated with the meetings and that the average age of those who attended seemed to be about 60, what I then said was: "I am old enough to remember when the enthusiasm of these meetings was such that the theatre and its gallery were crowded; and also an occasion on which those assembling at the College, for an annual meeting which had been called, found the gates of the College closed, and in consequence proceeded to the Holborn Restaurant, where an informal meeting was held"? All that I wished to imply was that the apparent lack of enthusiasm might be accounted for by the perennial rebuffs to the resolution—that the Members should be represented on the Council—which has been annually carried. At those crowded meetings distinguished Fellows and Members from London and the country used to speak in support of the resolution. *Fiat justitia.*

TUBERCULOSIS MORTALITY.

DR. HARLEY WILLIAMS writes: In the course of an address in Edinburgh on November 6th, to a report of which Dr. W. Camac Wilkinson draws attention (November 30th, p. 1040), I stated that of all deaths which occur in Scotland between the ages of 15 and 25, no less than one-third are caused by pulmonary tuberculosis. The figure is taken from the Registrar-General's report for 1928. This, of course, is not the same as saying that one person out of three between these ages dies of tuberculosis.

ASTROLOGY ON A BUSINESS FOOTING.

WE have received the following letter from a gentleman in Bengal, who describes himself as professor in charge of the All India Astrological Home:

> "I take the liberty to inform you that I have established an astrological home at S—— the ancient seat of sanscrit learing. With this object in view I take the opportunity to inform you for the benifit of our mutual co-operation and to develop the business in question. I am willing to put in touch with the people of your place should you favour me by inserting my advertisement in your paper on mutual co-operation & on the following terms. (1) You are at liberty to draw 50 % of the amount so realised against advertisement. (2) To avoid any difficulty the advertisement should be published under your care. Further I beg to say that I wish to act for you as a representative, reporter and advertising agent in this side and am in a position to contribute your requirements. By the way I shall be glad to send you a copy of my prediction, should you furnish me with your date, time & year of your birth. Please furnish me per return mail, if possible, a few copies of your specimen copies, together with your advt. rates."

COULD PREHISTORIC MAN SEE IN THE DARK?

MR. H. A. FLEMING (St. Margaret's-at-Cliffe) writes: I venture to send the following note with reference to Dr. Arthur T. Todd-White's letter on the above subject (November 9th, p. 884). When living in British Guiana, twenty-five years ago, I was staying at Bartica, at the junction of the Essequibo, Mazaruni, and Cuyuni Rivers. Living in the house was a little Guiana Indian boy (Macoushi tribe), about 10 years old, who used to accompany the Indian crew who manned the canoe. One night, when returning to Bartica from the Mazaruni River, we ran into very bad weather; the night was pitch dark, so dark in fact that I could not see my hand at arm's length before my face, but this small boy could see what we could not see. Standing in the bow of the canoe he directed the crew through a number of sharp-pointed rocks in the river, and we arrived home without mishap. The incident is perhaps worth recording, as showing the extraordinary sight in the dark of aboriginal Indian children born in the dense forests of Guiana.

A COMMUNICATION over the pseudonym "MEDEXIL" has been received from India, but the writer has omitted to give his name and address.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 72, 73, 74, 75, 78, 79, 80, and 81 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumteuencies at pages 76 and 77.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 255.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

501. Diabetes of Pituitary Origin.

E. MARTIN (*Rev. Med. de la Suisse Romande*, September, 1929, p. 693) discusses the pathology of pituitary tumours, with special reference to their association with glycosuria, and notes that in 90 per cent. of these cases the tumour is benign, consisting typically of eosinophil cells; malignant tumours, in his experience, do not give rise to diabetic symptoms. Pierre Marie noted 33 per cent. of glycosuria in his series of cases of pituitary tumours; Borchardt reported 63 cases of true diabetes and 8 of simple glycosuria in 176 cases. The present author records the case of a woman, aged 42 in 1919, who then showed signs of nervousness and irritability; in 1921 she developed acromegalic features; between these years a small adenoma of the thyroid had been removed. The menstrual periods ceased and bitemporal hemianopia developed. Deep *x*-ray therapy gave improvement till 1923, when double temporal decompression became necessary; in 1924 she became worse, and hypophysectomy was performed by the "tunnelization" method. Great improvement followed; the vision became better, menstruation returned, the extremities decreased in size, but the features remained as before. The patient received a course of salvarsan some time later for a suspected syphilitic lesion, but the drug was not tolerated well. In 1928 there was a sudden onset of diabetic symptoms; glycosuria and acetonuria were well marked. Treatment with insulin was begun, 200 units per day being given at first; the dosage was gradually reduced, and the patient is now doing well without it, though taking 100 grams of carbohydrate daily. Martin remarks that this case gives some plausibility to the hypothesis that diabetes is due to a polyglandular disorganization; there was evidence not only of pituitary disorder, but also of thyroid, ovarian, and pancreatic abnormalities. He considers that neither pressure in the region of the fourth ventricle nor alteration in hypophyseal secretion is sufficient to explain acromegalic diabetes, either alone or combined. Other observers have found alterations in the pancreatic "islets" in pituitary tumour cases and also changes in the pituitary gland (notably diminution in the number of eosinophil cells) in diabetes; some have also detected degenerative changes in the region of the tuber cinereum. Martin is inclined to support the hypothesis of the existence of a pituitary "neurocrine" system, whereby the secretion is carried along the pituitary stalk directly to carbohydrate-regulator centres in the brain. He suggests that the diabetic syndrome may have been precipitated in his case by visceral damage caused by the salvarsan.

502. Infectivity Indicated by the Tuberculin Test.

[illegible] bacilli during a year and a half all [illegible]dren admitted to the Fuglebakken [illegible]. V. POULSEN (*Nordisk Medicinsk* , 1929, p. 615) has sought an answer to the question whether children who react positively to the tuberculin test are infectious, whatever the site of their tuberculosis might be. On an empty stomach gastric lavage was performed with 200 to 300 *c.cm.* of sterile water; the resulting sediment was examined under the microscope after staining with the Ziehl-Neelsen method, was cultivated on Petroff's medium, and was injected into guinea-pigs. Altogether 67 children, whose ages ranged from 2 months to 8 years, were thus examined. Tubercle bacilli were found in 24 cases, the positive findings being most frequent among the youngest children. Thus, among the 14 infants under the age of 12 months there were as many as 12 in whom tubercle bacilli were found, but they were detected in only one out of 12 children between the ages of 3 and 4 years. Of 6 children suffering from tuberculous meningitis 3 were found to harbour tubercle bacilli in the stomach. The author accordingly recommends that tuberculin-positive infants should be regarded as infectious cases, and should, if possible, when admitted to hospital, be accommodated in a special tuberculosis department.

503. Endocrine Disorders among Jews.

W. M. KOGAN-JASSNY (*Ose Rundschau*, October, 1929, p. 1) discusses the prevalence among Jews of diabetes, obesity, the gout and uric acid diathesis, and diseases connected with disturbances of the internal secreting glands such as the pancreas, thyroid, and hypophysis. He finds that of 200 cases of diabetes 150 patients (75 per cent.) were Jews; in the Soviet hospital and two other clinics out of 135 cases 80 patients (64 per cent.) were of this race, and, considering all the cases together, over 70 per cent. of diabetics were of Jewish extraction. Over a period of three years 144 cases of obesity were observed, and of these 95, or 66 per cent., were Jews, 49 of whom, or 53 per cent., suffered from gout. The author admits that it is a disputed point whether there is a special disposition of the Jews to hypothyroidism and Basedow's disease, but he finds that out of 282 cases of hyperthyroidism 160, or 57 per cent., were Jews, which he associates with the distinctly more nervous character of the Semitic race. He considers it probable that the prevalence among Jews of endocrine diseases which are associated with carbohydrate, fat, protein, and especially purin metabolism, is connected with the irritation of the sympathetic nervous system persisting through the ages, the sedentary habits enforced by confinement in the Ghetto, and the predominant meat diet containing an excess of protein and purin substances which have injurious influences on people who take but little bodily exercise.

504. Erysipelas in Children.

H. B. CUSHING (*Canadian Med. Assoc. Journ.*, September, 1929, p. 276) records his observations on 80 cases of erysipelas treated at the Alexandra Hospital, Montreal, during the last five years; 39 were under the age of 1 year, so that erysipelas was nearly ten times as common in the first year of life as in any other year of childhood. Three groups of cases were distinguished: (1) facial erysipelas, in which there was high fever and delirium, but with a brief course and almost invariable recovery; (2) erysipelas of one extremity, usually the leg, in which the toxaemia was less, and recovery practically always occurred in a brief period; (3) erysipelas of the whole body, in which the mortality was very high and the course prolonged and irregular. Children under the age of 1 year almost always developed this form of erysipelas, while in older children the distribution of erysipelas was the same as in adults—namely, facial in 20 per cent., involving one extremity in 10 per cent., and the trunk in 10 per cent. Although erysipelas is a contagious disease, in only two instances was there a history of possible exposure to any other case. No drug given internally, such as ergot, tincture of iron, or quinine, influences its course; local applications, such as carbolic acid, mercurochrome, corrosive sublimate, iodine, or ichthyol, do not stop its spread, though some may give temporary relief. Serum treatment is disappointing, and most benefit can be derived from general care and skilful nursing, with the use of some soothing lotion or ointment.

Surgery.

505. Cardiolysis in Adhesive Pericarditis.

L. TORRACA (*Arch. Ital. di Chir.*, August, 1929, p. 405) reports a successful case of cardiolysis for chronic adhesive pericarditis, and discusses the subject fully, citing records of 84 cases. The author's patient was a boy, aged 15, who was admitted to hospital with cyanosis, dyspnoea, distended jugular veins, a fixed cardiac impulse, hydrothorax, enlargement of the liver, ascites, and oedema. Subperiosteal resection of the fourth, fifth, and sixth ribs was performed. The boy rapidly improved after the operation, and two years later was reported in good health. Of 84 cases collected, 72 patients derived more or less benefit from cardiolysis, 33 were still well one year later, 15 after two years, 7 after three years, and 5 after four years. The deaths numbered 30, 4 following the operation closely.

506. Hernia of the Bladder.

E. SCIAKY (*Il Policlinico, Sez. Prat.*, September 30*th*, 1929, p. 1383) reports a case of diverticulosis of the bladder with protrusion into the right inguinal canal, and discusses the pathogenesis and symptoms of this condition. There are three varieties of hernia of bladder: (1) the extraperitoneal; (2) the paraperitoneal (entero-cystocele), the most frequent, in which the anterior portion of the sac contains intestine, the bladder [illegible] from behind; and (3) the very r[illegible] further subdivision distinguis[illegible] 53 per cent.); a femoral type (27 [illegible] type (17 per cent.); and a smal[illegible] including the ischiatic, perineal [illegible] forms. Distension and reduced contractility are frequent causes. Alessandri suggested that hypertrophy of the prostate,

stricture of the urethra, congenital diverticulosis, and congenital or secondary asymmetry of bladder constituted favourable conditions for the production of vesical hernia. The symptoms are: incomplete reduction of a hernial protrusion which changes in volume in relation to the bladder content and not to impulses at coughing; desire to void urine after reduction; tenesmus; and the necessity of changing the position of body and compressing the hernia when it is desired to urinate. Catheterization, cysto-copy, and cysto-radiography may be valuable diagnostic aids, but the condition is generally recognized during operations for hernia, in which case partial cystectomy is the only treatment. The prognosis is good.

507. Splenomegaly in Egyptian Patients.

H. E. S. STIVEN (*Brit. Journ. Surg.*, October, 1929, p. 230) considers that splenomegaly among the Egyptian fellaheen is due to heavy infections of bilharzia of the rectal or *Bilharzia mansoni* types. Splenectomy, although a dangerous operation, is the only treatment, and out of 350 cases so dealt with good results were achieved in 69 per cent. of the cases which could be traced. The mortality rate was only 19 per cent., whereas without operation the expectation of life is extremely small. It is important that pre-operative treatment should be given for at least a month in order that the Egyptian parasites may be killed by carbon tetrachloride; moreover, a full course of tartar emetic and a course of antisyphilitic treatment must be given. A mixture of rhubarb and soda, and subsequently of iron and arsenic, with a full nourishing diet for several weeks, renders the patient better able to stand the shock of the operation. An injection of pneumococcal vaccine is given the evening before operation; without this precaution pneumonia is a certain complication. After the operation no fluid is given for twelve hours, with a view to prevent haemorrhage from some unsuspected ruptured vessel; the patient is kept on a fever diet for five days, after which a purge may be given, and a nourishing diet commenced. As a rule patients are well enough to leave hospital after fifteen days, and in two or three months are fit for work. Although splenectomy is a dangerous operation the improvement in health obtained by its means is held to justify the risk.

508. Thrombosis of External Pudic Artery in Chicken-pox.

A. H. BISSELL (*Arch. of Pediat.*, September, 1929, p. 588) records the case of a girl, aged 8 years, who on the fifth day of a mild attack of chicken-pox became very ill, with a temperature of 105°, and complained of severe abdominal pain, most marked on the left side just above the inguinal region and in the upper and inner part of the left thigh. The skin of the lower abdomen was dark red in colour; there was swelling in the inguinal region, and an ill-defined area showing early necrosis in the centre of the inguinal swelling. A culture of *Staphylococcus aureus* was obtained after forty-eight hours' growth. On the ninth day a well-demarcated area of gangrene was excised. This exposed the left pyramidalis and rectus on the inner side of the cavity and the external and internal oblique laterally. Under the lower edge of the cavity the thrombosed external pudic artery and vein could be seen ending in the gangrenous area. Recovery ensued in about five weeks.

509. Extra-articular Fixation of Sacro-iliac Joint.

W. M. PHELPS and M. K. LINDSAY (*Surg., Gynecol. and Obstet.*, October, 1929, p. 555) describe the extra-articular graft or tie beam method of fixing the sacro-iliac joint in order to afford a correct mechanical support comparatively simple in application and without opening the joint. An autogenous graft approximately 12 mm. wide is taken from the crest of the tibia and inserted through the bases of the posterior superior iliac spines; it is brought into contact with the posterior surface of the sacrum by removal of the spine of the second sacral segment. With these three points of contact it becomes fused and persists with adequate structural integrity to withstand the strains of traction and torsion associated with any motion in the sacro-iliac joints. The necessary exposure of the parts is obtained through a curvilinear incision, with its convexity upwards, connecting two points 3 cm. below and lateral to the posterior superior iliac spines. After clearing the iliac spines and the first and second sacral spinous processes with a periosteal elevator, and freeing the erector spinae muscles sufficiently to allow the passage of the graft, a tunnel is drilled; through this the graft is tapped into place with its medullary side placed downward to facilitate fusion over the sacrum. The graft maintains its position without other fixation. After closing the wound the patient is placed prone on a fracture bed, or Bradford frame, until the sutures are removed. In any case not involving a destructive process in the sacro-iliac joint, flexion and extension of the knees and hips may be started after three weeks' recumbency; when movement in the hips has become free and painless the patient may be allowed to get up. In three consecutive cases of intractable sacro-iliac pain, without any radiographic evidence of gross pathology, the patients who were treated thus returned to work within four months, and there were no symptoms a year later.

Therapeutics.

510. Treatment of Juvenile Diabetes.

FOR children suffering from diabetes A. E. FISCHER (*Amer. Journ. Dis. Child.*, August, 1929, p. 323) advocates a diet which permits of normal growth development, even though (in spite of insulin, which is always given) the child may develop a low glycosuria some time during the twenty-four hours. At the Mount Sinai Hospital new cases are taken into the wards for a period for observation and education, not only of the children but of the parents. Subsequently the child attends once every two or three weeks with a sample of each specimen of urine voided during the previous twenty-four hours and a record of all food eaten. Children under the age of 4 years receive 75 grams of carbohydrate; from 4 to 7 years, 80 to 90 grams; and from 10 to 14 years, 100 to 130 grams daily; this is exclusive of the carbohydrate in the protein and fat. The amount is divided so that two-fifths is given at breakfast and at supper and one-fifth at lunch. For smaller children, or for those who have a reaction to insulin, the diet is subdivided into five meals a day; 5 to 10 grams of carbohydrate are given at 10.30 a.m. and at 9.30 p.m., three and a half hours after the morning and evening doses of insulin. The average protein content of the diet is from 1.5 to 3 grams per kilogram per day, or from 10 to 15 per cent. of the total calories; the carbohydrate-fat ratio usually averages 1.1. The 20 diabetic children in the hospital receive insulin; 15 get two injections a day, the maximum dose being 35 units; 5 get three injections a day, with a maximum of 62 units. Subdividing the dosage of insulin when it seems that there is a loss of tolerance is frequently effective. None of the children receives only one injection a day. All children over the age of 9 or 10 inject insulin into themselves.

511. Malarial Therapy in Syphilitic Aortitis.

F. MIHALJEVIC and G. SPENGLER (*Wien. klin. Woch.*, September 19th, 1929, p. 1223) discuss the malarial treatment of syphilitic aortitis. Many of their patients were subjectively improved, but, objectively viewed, the aortitis was not influenced by malaria. Nevertheless, although malaria treatment is not a cure for syphilitic aortitis, the latter is considered by the authors to be no contraindication to the treatment, provided that no circulatory or cardiac failure exists. Their material comprised patients who had undergone malaria cure during the previous four years—30 cases in all; 24 were cases of aortitis simplex, and in 4 the aortic valves were also involved. Objective improvement occurred temporarily in 5 and permanently in 6 cases; it consisted in diminution of the anginoid symptoms. In 5 cases there was no subjective change, and in 9 no objective change; 8 patients felt worse, and in 12 the aortitis increased. In 4 cases valvular disease supervened later upon aortitis simplex. Two patients died, apparently not as a result of malaria. No death occurred as a result of circulatory failure during or after malarial therapy. In two cases this treatment had to be discontinued because cardiac insufficiency supervened. Other contraindications are arterio-sclerosis in the aged, cachexia, active pulmonary tuberculosis, and severe angina pectoris; the authors add that pure aortic valvular involvement is not a contraindication. Before and during malarial therapy prophylactic treatment should be undertaken against circulatory failure; this includes appropriate cardiac tonics and, when necessary, bed for several weeks. In the event of failure during treatment, discontinuance of malarial injections and the employment of cardiac tonics always restored the heart's strength.

512. Antimony in Schistosomiasis.

M. KHALIL, M. NAZMY, F. M. PETER, M. SALAH EL DIN, and M. H. EL BITASH (*Journ. Egyptian Med. Assoc.*, October, 1929, p. 137) contribute a joint report on the excellent results obtained in the treatment of schistosomiasis by a trivalent antimony compound, less toxic than tartar emetic, which has been prepared by the Bilharzia Research Section of the Public Health Department of Egypt working in conjunction with Messrs. Bayer. This preparation is a combination of the pyrocatechin disulphonate of sodium with antimony. It is unstable in the pure state, but keeps well in a 7 per cent. solution, which is injected intramuscularly in doses of 1 to 5 c.cm. The local reaction is slight, and the administration

is not followed immediately by coughing, vomiting, or fainting; vomiting occurred later in only 2 per cent. of the cases. The authors state that with this preparation, termed fouadin, two weeks' treatment is sufficient, as compared with four weeks' with tartar emetic. No deaths or serious symptoms occurred in a series of 200 cases so treated, and cure was obtained in all.

513. Treatment of Pyuria due to B. coli.

A. H. JOHANSEN (*Arch. Int. Med.*, September, 1929, p. 303) investigated experimentally and clinically the extent to which the power of phenyl salicylate to destroy *B. coli* in the urine is dependent upon the urinary reaction. It was found that the clinical results were improved when the urine was kept acid during the treatment with phenyl salicylate. A series is recorded of 24 patients with pyuria due to *B. coli*; in these patients a suitable degree of acidity of the urine was ensured, and 75 per cent. of cures resulted. The acidifying agent used was calcium chloride, 1 grain of which was given five times daily until the urine was proved to be acid by a qualitative test with methyl red. By adding two or three drops of a 1 per cent. solution of methyl red to 10 *c.cm.* of urine a suitable degree of acidity (pH less than 5.5) is indicated by the urine becoming red; if it remains yellow the dose of calcium chloride must be increased until the red reaction is obtained. Calcium chloride tablets may cause cardiac pain or dyspepsia, but this disadvantage can be avoided by coating them with phenyl salicylate so that the calcium chloride passes through the stomach without undergoing change; tablets containing 0.6 gram of calcium chloride and coated with 0.3 gram of phenyl salicylate were prepared for the author, and the administration of three tablets three times a day was found to produce an acid reaction within a few days without giving rise to dyspepsia or any ill effects. Since the coating of phenyl salicylate allows these tablets to pass through the stomach without any discomfort, they are also recommended by the author for cases of bronchial asthma, tetany, urticaria, or any condition in which treatment with calcium chloride is contraindicated because of the possibility of dyspeptic troubles.

Ophthalmology.

514. Circinate Retinitis.

H. W. SCARLETT (*Amer. Journ. Ophthalmol.*, August, 1929, p. 633) reviews a case of circinate retinitis in a man, aged 73, who presented badly sclerotic retinal vessels. His vision was 6/9 in the right eye, and he was only able to count fingers with the left. The right macular region presented two small atrophic white spots surrounded by yellow dots. The left eye had a series of haemorrhages to the temporal side of the disc, accompanied at first by a broken crescent of whitish-brown dots, and below the inferior macular vessels two confluent white patches of exudate. A few months later these two patches had united, and the haemorrhages had been almost absorbed; there was an irregular crescent of exudative areas, the ends of the crescent resting on the upper and lower temporal edges of the disc. Similar developments, but at an earlier stage, were proceeding in the right fundus. Scarlett remarks that the exact etiology of circinate retinitis has not been definitely determined; most observers, however, agree that arterio-sclerosis is a potent factor. Possibly [illegible] to the exudative foci. Usually some [illegible] is recorded in the patient, or mem[illegible]he case he describes, the patient's mother and sister died of pulmonary tuberculosis. Macular vision is frequently diminished, although improvements occur before the final stage. It is quite characteristic of the disease that patches of exudate appear and disappear several times, and may occur, in almost any shape, in places other than the perimacular region.

515. Cataracts of Diabetic Origin.

J. GALINDEZ (*La med. Ibera*, September 14th, 1929, p. 260) has attempted to confirm Marañon's suggestion that many diabetics first present themselves complaining only of cataract. The question is not to be settled by a mere examination of the cataract, for clinically, or even at biopsy, it was impossible to distinguish a diabetic from the so-called senile cataract; it could only be solved by estimating the percentage of diabetics among patients with cataract. Undoubtedly much of the previous disagreement on this point was due to the fact that the older methods of diagnosing diabetics were imperfect. Using the Folin-Wu blood sugar method, glucose tolerance tests were performed on 51 cases of cataract. In 30 the blood sugar rose more than 50 per cent. above its resting value and had not returned to normal in seventy minutes; these patients were therefore diagnosed as pre-diabetic or diabetic. The ages of 287 diabetic patients were recorded; this showed that liability to diabetes steadily increases with age (up to 70 years). Cataract being chiefly due to diabetes, it is therefore not surprising that it should have been ascribed to age. The cases investigated indicate also a causative relation between glaucoma and diabetes. Galindez remarks that since diabetes is often the cause of cataract, the latter should benefit from a diabetic regime; and two cases are described where this occurred. Because many old diabetic patients, particularly if they have renal arterio-sclerosis, have a high renal threshold, diagnosis by urinary analysis is uncertain. A glucose tolerance test is necessary, especially if the question of operation arises. In one such case with double cataract no diagnosis of diabetes was made because urinary sugar was not present. One eye was operated on, and within twelve hours there began an infection which culminated in panophthalmitis. At this stage the urinary sugar had increased to the diabetic level, and the blood sugar figure was 322. Suitable dieting and insulin [illegible] the blood sugar to 150, and [illegible] Enucleation of the previously infected eye and extraction of cataract from the other were then performed with success, and recovery was uneventful. The author adds that an operation on a patient with a diabetic cataract should be performed only when the blood sugar figure is normal, and this figure should be maintained throughout convalescence.

516. Hypertensive Retinal Disease.

ACCORDING to L. T. GAGER (*Arch. of Ophthalmol.*, September, 1929, p. 307) changes in the optic fundus indicate more definitely even than functional tests the progress of hypertension, and its benign or malignant character. The structural changes in the retinal arteries caused by hypertension may remain after the heart has failed and the blood pressure has fallen as the only distinctive sign of the previous condition. The retinal changes occurring with hypertension and the hypertensive diseases with which they are associated are briefly discussed. These changes may be divided into two main groups. First there are the alterations of a purely vascular nature; these occur in three stages—spasm of the retinal arterioles, arterio-sclerosis, and haemorrhage. The second group comprises lesions of an inflammatory character, though often a vascular component is also present. These changes include oedema, retinal and papillary, and those spots called "exudate." Further, there are proliferative, degenerative, and atrophic changes, but these are secondary. Hypertension is the expression of an increased tonus in the arterioles of the body, which can be detected by the ophthalmoscope as vascular spasm. Under the functional or kinetic strain of increased blood pressure structural changes occur in the intima and media of these arterioles. Partly in the nature of a work hypertrophy, these changes are distinct from those of senile arterio-sclerosis, and are independent of antecedent kidney disease. These lesions, observable with the ophthalmoscope, are of practical importance in the diagnosis and prognosis of systemic disease. Haemorrhage into the retina, associated with arterio-sclerosis, indicates the progress of hypertension, and, if extensive, suggests the malign character of the process. Exudation is a phenomenon almost exclusively associated with hypertension. If it occurs without vascular sclerosis a purely inflammatory process, including nephritis, is likely. In the presence of retinal arterio-sclerosis, exudation is often not inflammatory. It indicates an advanced stage or, associated with haemorrhage and oedema, the malignant type of hypertension. The differentiation of the inflammatory lesions is of importance, since nephritis and vasculitis often respond readily to treatment. Moreover, the early recognition of hypertensive vascular disease is essential to the most effective management of the patient.

Obstetrics and Gynaecology.

517. The Time of Ovulation.

H. KNAUS (*Zentralbl. f. Gynäk.*, August 31st, 1929, p. 2193) remarks that the opinion is widely held that in women with a regular twenty-eight-day menstrual cycle ovulation takes place at a time which varies widely between the eighth and twenty-third days. Fraenkel and Schröder, however, believe that in the majority of cases ovulation occurs from the fourteenth to sixteenth day; and experimental evidence is adduced by Knaus which supports that conclusion. In rabbits the uterus fails to contract, in response to injection of extracts of the posterior lobe of the pituitary, when a corpus luteum is present, and contracts normally when it has been destroyed. Conversely, the existence of a corpus luteum is indicated when uterine contractions fail to follow the injection of pituitary extract. In women in whom these contractions were graphically recorded by connecting the

uterine cavity (filled with iodipin) with a mercury manometer, the reaction to the intravenous injection of 0.1 to 0.25 c.cm. of pituitary extract was recorded at varying times between menstruations. From the second to the fifteenth day contractions were noted; from the sixteenth day a response to the pituitary hormone was absent for some days onwards. Three days before menstruation Knaus found the pituitary response absent; one day before menstruation it had returned. The conclusion is drawn that the influence of the corpus luteum becomes manifest at the sixteenth day, ovulation preceding it within forty-eight hours. Observations in women with shorter menstrual cycles pointed to ovulation before the fourteenth day. The case is described of a sterile married woman, aged 35, in whom ovulation, tested by the response to pituitary injections, occurred regularly on the twentieth day; the sterility is explained by the inference that in these conditions an impregnated ovum would reach the uterus during its menstrual phase.

518. Labour in Elderly Primiparae.

MARGARET SCHULZE (*Journ. Amer. Med. Assoc.*, September 14th, 1929, p. 824) suggests that the dangers and difficulties of labour in elderly primiparae may have been somewhat exaggerated; she discusses the labours of 357 patients whose ages ranged from 30 to 45. The study of these cases showed that, speaking generally, neither foetal nor maternal mortality was increased above levels generally accepted as normal, and the average duration of labour was only slightly prolonged. About 20 per cent. of the women had strikingly rapid and easy labours. Dystocia, including excessive length of labour or its termination in maternal exhaustion, and conditions necessitating major operative procedures, may be expected in about 15 per cent. of cases, but is usually dependent on complicating factors rather than on the age alone. A careful consideration of the patient will usually permit of a fairly accurate prognosis even before labour starts. Abnormal presentations and contracted pelves, both of which are more frequent than in younger patients, increase the necessity for operative intervention and with it the danger to both mother and child. Apart from malpresentations and contracted pelves, the complications of labour in the present series of cases were remarkably few. The most important single factor in prognosis is the quality of the uterine contractions, but this cannot be accurately prognosticated until after labour has begun. The frequency of inadequate pains increases with advancing age, and probably a consideration of the physical type of patient and other history, such as that of a previous long-standing sterility, will be of greater importance the more accurately it is observed. The development of the cervical form of Caesarean section makes it possible, without materially increasing the maternal risk, to await labour, observe the type of uterine contractions, and then, if these seem inadequate, perform Caesarean section. A rather high percentage of these operations will probably always be necessary, especially in the older women and in those with long-standing sterility, for the greatly increased value of the child in these cases makes it desirable to minimize foetal risk.

519. Typhoid Infection of an Ovarian Cyst.

J. TAPIE, L. MOREL, A. LYON, and F.-X. BERTRAND (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, October 28th, 1929, p. 1184), who record a personal case in a woman, aged 22, successfully treated by laparotomy, illustrate the rarity of suppuration of an ovarian cyst in typhoid fever by the fact that they have been able to find only twenty cases on record. The typhoid bacillus in such cases reaches the ovary by adhesions uniting it to the intestine, or through the blood stream, and finds in the cyst an excellent culture medium. Infection of the cyst probably takes place in the early stage of typhoid fever, but the peritoneal manifestations occur at very variable dates. The suppuration is nearly always unilateral, and *B. typhosus* is almost invariably the organism responsible; *B. paratyphosus* B was only isolated in Corscaden's case. Staphylococci and *B. coli* are hardly ever found in association with the typhoid infection, except when there is a secondary suppuration of the abdominal wall. The difficulties in diagnosis depend on the period of typhoid fever at which the complication develops. During the acute stage the error consists in overlooking the cyst, and attributing the peritoneal syndrom to perforative peritonitis. The latter, however, has a more sudden onset with early contracture of the abdominal wall; the abdominal signs rapidly become generalized, and the hepatic dullness soon disappears. The condition must also be diagnosed from encysted peritonitis, in which there is not the regular outline or special resistance of the cyst. It is less usual to diagnose the ovarian cyst and overlook the typhoid infection, regarding the condition as merely an ordinary infection of an ovarian cyst. If left untreated suppuration of an ovarian cyst has a very gloomy prognosis, whereas remarkably successful results can be obtained by early operation.

Pathology.

520. Dangers in Antirachitic Medication.

I. JUNDELL (*Monatsk. f. Kinderheilk.*, August, 1929, p. 67) has investigated the possibility of harm being done by anti rachitic medication. Two hundred mice were arranged in groups in each of which some served as controls, while the others received various augmented dietaries. After intervals ranging from two to thirteen months the animals were killed and examined for chronic cardiac changes. Large doses of different preparations comparable with those given to children were used. Mice in one series were fed on normal diet and either irradiated ergosterin or cod-liver oil. All contracted cardiac lesions; the control animals were unaffected. Mice in another series, receiving a mixed diet containing egg yolk, suffered similarly. To prove that this was not due to vitamin B deficiency a third group of mice was given the same diet, with the addition of irradiated ergosterin and cod-liver oil, but similar cardiac changes occurred. The cardiac changes still appeared when lemon juice was added, thus excluding vitamin C deficiency. Another series was broken up into six subgroups, all the mice being fed on the fir t-mentioned diet. Subgroup (1) received the diet without any addition. Subgroup (2) were given also the oil in which the ergosterin had been dissolved. No cardiac change was detected in the animals in either group. The mice in subgroup (3) received an addition of non-irradiated ergo-terin dissolved in oil, and the mice in subgroup (4) had the same without oil. Both groups of mice suffered from cardiac changes. The remaining animals were given irradiated ergosterin, and much the same cardiac lesions became manifest. Thus ergosterin, whether irradiated or not, had the same bad effect. A last series of mice fed on normal diet received ultra-violet treatment; after two and a half months their hearts developed the same pathological condition—namely, degenerative myocardial changes of very varying intensity even in the same groups. The degenerated masses were more numerous at the apex and fibrosis was conspicuous; in some mice myocardial deposits of calcium were detected. From these researches the author concludes that human beings may suffer from the effect of too violent antirachitic measures, though he agrees that it will be long before the nature of these changes, and their precise relation to dosage, can be determined.

521. Experimental Rabies.

P. REMLINGER and J. BAILLY (*C. R. Soc. de Biologie*, November 4th, 1929, p. 376) have investigated the transmission of rabies to pigeons. The natural disease has never been observed, but experimentally it has proved possible to reproduce it in a certain proportion of pigeons. Fixed virus proved comparatively avirulent; thus of 54 pigeons inoculated intracerebrally, only 15 developed the disease. The street virus apparently proved more virulent. After inoculation with this virus there is an incubation period of twelve to twenty-four days; the illness that follows is chiefly noticeable for disturbances of equilibrium, cachexia, and progressive paralysis, affecting the legs and wings. The bird is able to feed itself, even in the severe forms of illness; though there may be difficulty in seizing a particle of grain, once it has been transferred to the mouth it is swallowed with perfect ease. Death, which occurs in rather less than half the cases inoculated with street virus, does not take place till about the eighth or tenth day of illness. At necropsy the lesions are exclusively micro-copical; they are most evident in the cerebellum, less so in the cerebrum, and least in the cord. They consis of an encephalo-myelitis characterized by interstitial inflammation, especially of the perivascular type. Negri bodies are found in the pyramidal cells of the cerebrum, but not in the Purkinje cells of the cerebellum.

522. B. faecalis alkaligenes as a Cause of Pyrexia.

N. DANBOLT (*Norsk Mag. f. Laegevid.*, October, 1929, p. 1052) records a case in a previously healthy young soldier who was operated on for appendicitis thirty hours after the onset of the attack. The operation was uncomplicated, but fever persisted without it being possible to account for it. Since the condition simulated typhoid fever, a blood culture was taken and a Widal test performed on the eleventh day. The agglutination test was negative for *B. typhosus* and *B. paratyphosus* A and B, but the blood culture showed the growth of an organism which had all the characteristic features of *B. faecalis alkaligenes*; this organism was agglutinated in the patient's serum in a dilution of 1 in 80. During the disease this titre fell to 1 in 20, and to *nil* after the commencement of convalescence. Danbolt concludes that this micro organism was the infective agent, and he thinks that it was derived from the intestinal contents. It might have played a part in the production of appendicitis, or have gained entrance to the body during the appendicitis or during the course of the operation.

de KUYPER'S
HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

FELAMINE BRAND SANDOZ

SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

AGENCY:-
SANDOZ CHEMICAL WORKS PHARMACEUTICAL DEPT.
5, WIGMORE STREET, LONDON, W. 1.

PHYSIOLOGICAL TREATMENT OF CONSTIPATION

COMPOSED OF

EXTRACT OF THE INTESTINAL GLANDS

which strengthens the glandular secretions of the organ.

BILIARY EXTRACT

which regulates the secretion of the bile.

AGAR-AGAR

which rehydrates the contents of the intestines.

LACTIC FERMENTS

anti-microbian and anti-poisonous action.

IN TABLET FORM.

GLYCO-THYMOLINE

The oro-nasal antiseptic and prophylactic

As a general antiseptic fluid, Glyco-Thymoline has a wide range of usefulness. It is non-irritant and deodorant. It does not coagulate albumen. Its action on the mucous membrane is prompt. Relief is immediately felt by the patient, even in the most advanced stages of naso-pharyngeal catarrh, in acute coryza, pharyn-gitis, influenza, and septic conditions of the mouth.

By a recent concession of the Commissioners of Customs and Excise, Glyco-Thymoline may now be supplied on a medical man's prescription in "dispensing" packages. Prices in such cases are:

3 oz.	1s. 1½d.
6 oz.	2s. 3d.
1 lb.	4s. 6d.

Usual discounts to the profession.

THOS. CHRISTY & CO. 4-12 OLD SWAN LANE, LONDON, E.C.4.

INFLUENZAL "COLDS"

Alkaline therapy in some form has given the best results in all the recent epidemics of influenza and colds. The particular form of alkaline therapy represented by the administration of SALVITAE has always, when given a fair trial, proved to be the most dependable resource of all.

Samples and Literature on request to Sole Agents: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

A formula that demonstrates its scientific value.

Salvitae

Two sizes, 4/6 and 7/-.

Manufactured by American Apothecaries Co., New York.

Emol-Keleet

Samples free to the Medical Profession on request.

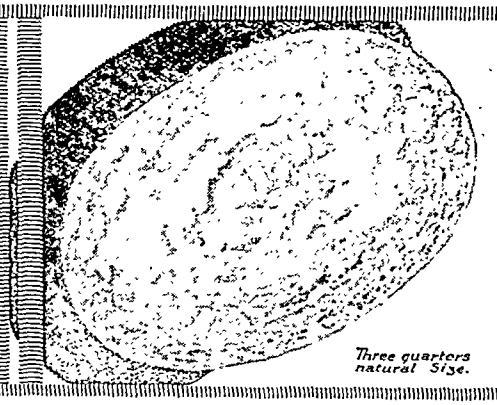
FASSETT & JOHNSON, Ltd.
86, Clerkenwell Road, London, E.C.1.

The Natural Sedative Emollient DUSTING POWDER.

ALLAYS PRURITUS AND PRURIGO.

Promptly alleviates the distressing irritation of Eczema Herpes, Urticaria, Lichen, &c.

Equally beneficial in the rashes of Measles, Scarlatina also in eruptions following Vaccination. A perfectly bland impalpable powder, peculiarly soothing, absorbent, and mildly astringent.



Three quarters natural Size.

Bath Rusks

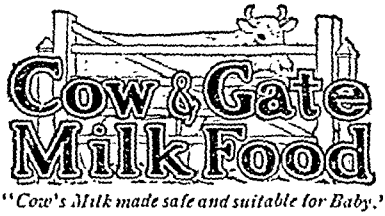
HUMAN TUBERCULOSIS OF BOVINE ORIGIN

At the recent B.M.A. Conference held in Manchester reference was made to this important subject, of which the following abstracts (Lancet, Oct. 19, 1929, p. 824) are typical:—

"Dr. ———, M.O.H., in opening the discussion, estimated the human deaths caused annually by the bovine tubercle bacillus at 1,000 to 2,000. Most of them were the deaths of children, and we had no knowledge as to how many non-fatal infections occurred. As to the extent of bovine tuberculosis among cattle in this country, he thought that about 40 per cent. of the cows were infected; that about 1 per cent. of the cows were 'open' cases; and that about 0·3 per cent. had tuberculosis of the udder."

"Dr. ———, M.O.H., thought that 5 per cent. of the cows had diagnosable tuberculosis. He had found certified milk highly infected with tubercle bacilli. The graded milks were a failure, and pasteurisation was only doubtfully safe. He believed that milk dried by the roller process was the best solution, and he looked forward to the establishment of milk-drying factories throughout the country."



"Cow's Milk made safe and suitable for Baby."

This annual toll of human life, which is mostly confined to young babies, can be eliminated by a suitable heat treatment of the milk. Processes such as pasteurisation have their limitations so far as the feeding of infants is concerned, particularly in view of their disturbing influence on the mineral and vitamin content of milk.

The bacteriological sterilisation of milk is assured by the COW & GATE Improved Roller Process, which also effects maximum preservation of the vitamin content with minimum disturbance of the mineral salts.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

In Treating Movable or Floating Kidney

Proper Abdominal Support Is of the Greatest Service

An abdominal support, to be of aid in treating movable or floating kidney, should, it is agreed, support the abdomen from below, upward and backward. It should fit snugly. It should reach from the pubic bone to the umbilicus.

The Spencer abdominal belt and supporting corset meet these requirements with absolute perfection.

Each garment is designed from complete body measurements and figure description to meet the individual requirements of the patient who will wear it.

SPENCER ABDOMINAL BELT.

The support should be applied with the patient recumbent, pelvis raised, knees drawn up.

Usually, the support itself, used in co-ordination with the regimen prescribed by the physician, will give relief without pads. Pads will, however, be provided with the support when the physician prescribes them.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

The Spencer support for movable or floating kidney is adjusted over each hip by a series of tapes and self-locking buckles.

The patient can readily adjust a Spencer support alone, except in unusual cases.

We issue the following booklets on the use of Spencer Supports: Sacro-iliac Strain, Hernia, Enteroptosis and Intestinal Stasis, Movable Kidney, Pregnancy and Postpartum Support, The Corset as a Therapeutic Agent. We will gladly send you any of them in which you are interested.

An ACHIEVEMENT IN SCIENTIFIC CONSTRUCTION

"EMESAY POPULAR" MODEL OPERATING TABLE
£45
100% BRITISH.

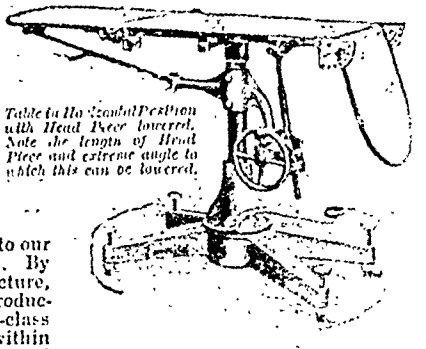

Table in Head Position with Head Piece lowered. Note the length of Head Piece and extreme angle to which this can be lowered.

ESSENTIALLY similar in design to our well-known "Universal" Model. By the experience gained in its manufacture, and the use of modern methods of production, we are able to offer a first-class heavy and stable Table at a price within the reach of the smaller Hospitals and Nursing Homes.

Its range of movements makes it suitable for any operation required by Modern Surgery.

The perfection of its design has been proved by the unqualified commendation expressed by users of the original model of which the Popular Model is an offspring.

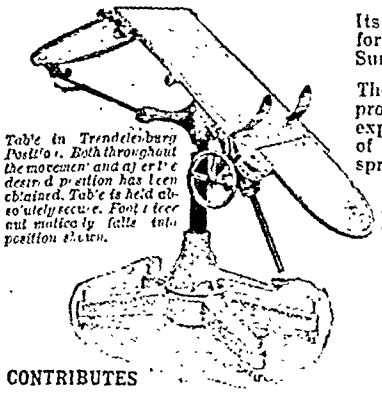

Table in Trendelenburg Position. Both throughout the movement and at extreme desired position has been obtained. Table is held absolutely secure. Foot piece automatically falls into position shown.

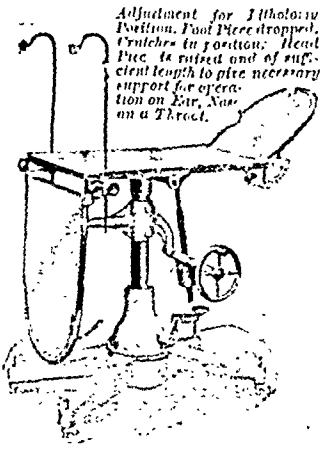

Adjustment for Tracheotomy Position. Foot Piece dropped. Crutches in position. Head Piece is raised and of sufficient length to give necessary support for operation on Ear, Nose and Throat.

SEND FOR DESCRIPTIVE BOOKLET (B) or call at any of our Showrooms for demonstration.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

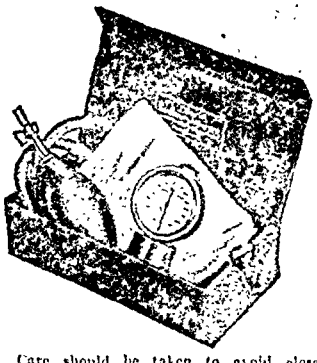
Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health . . . and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition. . . . MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an operating theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facilitiy for occupying themselves in farming, gardening and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the shore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 65, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE FLOWER HOUSE,
BECKENHAM LANE, S.E.6.

Telephone: LEE GREEN 1993.
(Eight miles from London.)

A PRIVATE HOME of the highest class for Gentlemen suffering from Mental and Nervous Disorders, both under Certificates and as Voluntary Boarders.

A beautifully furnished old family mansion, thoroughly modernized, and up-to-date.

Twenty-five acres of well timbered grounds, containing unrivalled flower gardens, cricket and football fields, croquet, tennis and bowls. Billiard room, private theatre, and wireless.

Voluntary Boarders accepted

Apply for particulars to Dr. SANKEY.

THE RADIUM INSTITUTE

16, RIDING HOUSE STREET, W.1

Patron: HIS MAJESTY THE KING. *President*: SIR GEORGE BLACKER, C.B.E., M.D., F.R.C.S.

Medical Superintendent: A. E. HAYWARD PINCH, F.R.C.S.

THE Institute was established in 1911 for the Treatment of Patients by Radium, and for Researches into the Therapeutic Properties of Radium and Radio-Active Substances.

An in-patient department, which has recently been doubled in size, exists for the reception of special cases or of patients from the provinces. Private rooms are provided for paying, and wards for necessitous cases.

There is an extensive and adequately equipped out-patient department.

No case, however, can be received until after arrangements have been made with the Institute by the patient's medical attendant.

The most recent form of deep X-Ray Therapy plant is now in process of installation, and X-Ray treatment combined with Radium will be available for patients.

Plates, tubes, needles, and seeds containing Radium Emanation (Radon) are supplied to Medical Practitioners at moderate charges.

The Institute undertakes the estimation of the activity of Radium and Radio-Active Substances, the measurement of Radium Salts, and the preparation of Radium Applicators.

THOMAS A. GARNER, F.C.I.S., Secretary.

RUTHIN CASTLE

(FORMERLY DUFF HOUSE, BANFF.)

The first Private Hospital in the United Kingdom to be fully provided with a whole-time specially qualified Staff of Doctors, Analytical Chemists, Bacteriologists, Radiologists, Nurses, Dietists, Masseurs, and Masseuses, and a full equipment of Laboratories, X-rays, Electrocardiograph, Artificial Sunlight, and Medical Baths.

The Hospital is equipped for the diagnosis and treatment of any form of ill-health, except Mental and Infectious Diseases. The fees are inclusive.

The climate is mild and the neighbourhood beautiful. Apply: The Secretary,

Telegrams: Castle, Ruthin. Telephone: 66, Ruthin. Ruthin Castle, North Wales.

NEURALGIA AND NEURITIS

Few diseases cause so much suffering as nerve pains, such as sciatica, trigeminal neuralgia, brachialgia, and intercostal neuralgia.
This group of diseases is rapidly and effectively treated at Pistany (Czechoslovakia) by volcanic mud—driven to the surface by hot sulphur springs. Statistics show that of 100 patients, only less than 5% do not respond to the treatment 30% are completely relieved and 65% are considerably improved.
Pistany RADIO-ACTIVE Mud Packs and Compresses are simply and easily applied. This treatment may be successfully combined with other physiotherapeutic methods.

NDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in 's Indian Medical Service. The terms offered include a gratuity of £1,000 on ent after six years' service, or £2,500 after 12 years' service, together with return passages, for those who no longer desire to remain in the Service other respects the terms will be as detailed below.

andidates must be British subjects under 32 years of at the time of application, and must be registered ler the Medical Acts in force in Great Britain and ıtern Ireland.

CAREERS.

ne Indian Medical Service offers wide opportunities medical experience, including clinical, preventive, cialist, and research work. At the beginning of his eer an officer is employed on the military side, which medical charge of the Indian Army. Promotion is on ime scale up to the rank of Lieutenant-Colonel, and by ction to the ranks of Colonel and Major-General. An cer may apply after two years' Indian service for nsfer to the civil side, from which appointments are de to Civil Surgeoncies, which are established at the incipal civil centres to provide for the medical needs of il officials and for general medical administrative rposes; to specialist (for example, public health and cteriological) services; to research posts; and to ofessorships at the Medical Schools.

PAY.

ne monthly rates of pay for European officers in the rvice who have a "non-Asiatic" domicile are as follows:

	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
		500	150	1st
			150	2nd
			150	3rd
			150	4th
	(i) During first 3 years' service as Captain	650	£15	5th
			£15	6th
			£25	7th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	8th
			£25	9th
			£25	10th
	(iii) With more than 6 years' service as Captain	850	£25	11th
			£30	12th
jor	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

... ..AS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in January to make nominations, and the selected candidates will be required to attend a course of instruction commencing on or about the 1st February, 1930.

Burgh of Kilmarnock.

MEDICAL OFFICER OF HEALTH.

The Town Council invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health or an equivalent qualification, for the appointment of Medical Officer of Health for the Burgh. Candidates must not exceed 45 years of age.

The person appointed will be required to carry out all the duties pertaining to the position of Medical Officer of Health under the Scottish Burgh Police, Infectious Diseases, Notification of Births, Public Health, Housing, Milk and Dairies, Food and Drugs, Blind Persons, and Local Government Acts, and all other relative Statutes and Orders. The appointment will include the duties of Medical Officer of Kirklandside Infectious Diseases Hospital, Raimshill Tuberculosis Sanatorium, the Maternity Home and Child Welfare Centre, and the Clinic for the treatment of Venereal Diseases; the duties as Tuberculosis Officer, Police Surgeon, and Medical Officer of Model Lodging House; and, from May 15th, 1930, the duties of the Medical Officer under the Scottish Poor Law, Lunacy and Mental Deficiency, and Vaccination Acts, and all other relative Statutes and Orders. The appointment will also include generally any other responsibility or work (including work in connection with medical inspection and treatment of school children and hospital facilities for the treatment of sick persons) that may be assigned to the Medical Officer of Health by the Town Council either by themselves or in conjunction with any other Public Authority or Body.

The person appointed will be required to devote the whole of his time to the duties of the office and to reside in the Burgh. He will not be allowed to engage in private practice, and all fees which may be paid to or received by him must be paid over to the Corporation. Applicants should have had previous experience in the various branches of the work.

The inclusive annual salary is £870, and the appointment is subject to the approval of the Department of Health for Scotland. The successful candidate will be required to pass a medical examination.

Copies of the Specification of Duties and Conditions of Appointment may be obtained from the Subscriber, with whom applications (enclosed in envelopes endorsed "Medical Officer of Health"), stating age, qualifications, previous experience and present employment, together with one copy of recent testimonials, should be lodged by December 14th.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London. Telephone: Mayfair 1782, 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

NORTHERN BRANCH.

The Manchester Medical Agency, lately under the control and management of the Manchester Medical Committee, has now been taken over by the British Medical Bureau as their Northern Branch.

Medical Practitioners in the North requiring the services of the Bureau are recommended to consult the Branch Manager, at the Offices, 3, Cross Street, Manchester.

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES, who have both had many years' experience as Medical Transfer Agents.

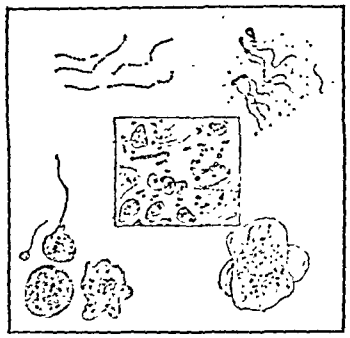
The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. NORTH MIDLANDS.—Well-established mixed-class PRACTICE situated in a town of nearly 20,000 inhabitants, with large surrounding district. Cash receipts about £2,000 p.a., including club of £250 and panel of 1,000. Expenses light. Good house, with ample accommodation. Would be let or sold. *Premium* for an immediate sale £2,000.
2. PARTNERSHIP.—SOUTH WEST.—(Within 100 miles of London).—Partner required, experienced in surgery, to take over a fourth, third, or half share in a very old-established Practice in a desirable country town. Income over £4,200 p.a. (this year to end of Oct. £4,455), including appts. £300 and panel of 1,950. Visits up to 31/6. Good house, with ample accommodation. Price, freehold, £2,000. Prem. for share 2 years' purchase. Up-to-date Cott. Hosp.
3. EASTERN COUNTIES.—Very attractive Village within 100 miles of London. Old-established, practically unopposed, mixed-class PRACTICE, averaging about £1,250 p.a. Panel of over 700. Advice and medicine 3/6 to 5/-. Visits 5/- to 10/6, a few at 21/-. Large detached house, in perfect order and with every modern convenience. Price for freehold £1,650. Premium £1,600.
4. PARTNERSHIP. — ESSEX. — (Within 30 miles of London). — Third Partner required in very old-established rapidly increasing Practice in small country town. Cash receipts for past three years average £5,755 (last year £4,176), including panel of 2,200 and appts. Third share is for disposal. Opposition slight. Visits 5/- to 21/-. Good house, professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Large garden. Garage. Rent £60. Premium 2 years' purchase. Educational facilities and sport.
5. HERTS.—Old-established chiefly better-class Country PRACTICE, in delightful district within easy reach of London. Receipts average £1,000 p.a. Panel of nearly 500 and appts. worth £60. Visits 3/6 to 21/-. Exceptionally nice house, with all modern conveniences, and half acre of garden. Price for freehold £1,800. Prem. £1,400.
6. ESSEX.—(Within 15 miles of London).—Old-established, unopposed and increasing PRACTICE, in pretty country district. Income last year over £1,100, including Union £90 and panel £432. Comfortable house, with ample accommodation (water laid on) and large garden. Rent £70 p.a. on lease. Premium £1,650. Ill health reason for sale.
7. HOME COUNTIES.—Within few miles of large town.—Old-established unopposed and increasing PRACTICE, in pleasant district, worth over £3,000 p.a., including panel, with mileage, producing about £1,000 and appts. £250. Visits 3/6 to 10/6, medicine usually extra. Very little midwifery. Good house (7 bedrooms, etc.), garden, garage. Price, freehold, £2,000. Premium 1½ years' purchase.
8. *X-RAY AND ELECTRO-THERAPEUTIC CONNECTION*, in popular South Coast Watering-place. Receipts, which are rapidly increasing and include resident patients for treatment, amounted last year to nearly £800. Large house and garden. Price, freehold, £6,500. Premium 1½ years' purchase. Opposition very slight and the *investment offers considerable scope.*
9. DEATH VACANCY.—HOME COUNTIES.—(Within one hour's run of London).—Old-established unopposed PRACTICE in pretty district within few miles of a town. Receipts average over £1,400 p.a., including appts. £100 and panel of about 800. Visits 2/6 to 21/-, medicine extra. Railway station in place. Good house (5 bedrooms, bathroom, etc.), with large garage. Electric light and gas. Price, freehold, £1,800, of which £1,500 can remain on mortgage. Premium only £1,400. Educational facilities. *Excellent Locum in charge.*
10. [illegible] within easy reach of Manchester.—producing £2,600 p.a., with panel of [illegible] medicine extra. Good house, with ample [illegible]00, or would be rented at £70 p.a. Pre[illegible] half down and balance by instalments.
11. LANCS. — LARGE TOWN. — Better-class *non-panel, non-dispensing* PRACTICE, offering large scope for surgery to anyone having the F.R.C.S. Income for last 12 months £1,500. Fees 7/6, 10/6, and 21/-. Good house, with ample accommodation and well situated. Price £700, £450 *on mortgage; or might be let.* Premium £1 200.
12. ESSEX.—POPULAR COAST TOWN.—Small easily worked PRACTICE, offering good scope, as district developing. Income last year £530. Panel of 200. Fees 2/6 to 7/6. House contains 2 reception, 3 bedrooms, etc. Garden. For sale or on rental. Premium £850, part down and balance instalments.
13. PARTNERSHIP.—WITHIN 40 MILES OF LONDON.—Pleasant Town.—A one-third share in a very old-established mixed-class Practice, averaging over £3,400 p.a. Panel of 1,900 and appts. worth £540. Fees 2/6 to 2 gns. Mid. from 2 to 20 gns. Suitable house, with ample accommodation, Garage. Rent on lease £65 p.a. £2,650.
14. [illegible] Country PRACTICE in very favourite [illegible]ndon. Income at present about £500, but offering large scope. Fees 3/6 to 10/6. Convenient house, with 2 reception, 5 bedrooms, etc., can be rented on lease at £75 p.a. Premium £500, payable easy terms. Locum in charge.
15. LONDON, NORTH-WEST.—RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-fourth share (up to one-half in 12 months) in a very old-established non-panel and non-dispensing better-class Practice. Average income £6 000. Fees 7/6 to 10/6. Large double-fronted house available. Senior Partner retiring. Premium 2 years' purchase.
16. SOUTH WALES.—Seaside Resort.—*Old established mixed-class* PRACTICE in favourite county, *receipts for past* 12 months £1,900, including panel of 607. Visits 5/6 to 21/-. Convenient house, with 2 reception, 4—6 bedrooms, and professional rooms, etc. Rent on lease £60 p.a. Good sport and schools. Prem. 1½ yrs.' purchase.
17. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—*Old-established increasing* PRACTICE, held over 20 years, on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,500, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,500, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.
18. CROYDON AREA.—PARTNERSHIP.—A two-fifths share to commence with in an old-established middle-class Practice, income £2,700. *Panel of 988. Fees 5/6 to 10/6. Convenient house on lease.* Rent £80 p.a. Premium 2 years' purchase.
19. PARTNERSHIP.—FAVOURITE SOUTH COAST WATERING-PLACE.—Third Partner required in very old-established mixed class and increasing Practice, the income of which for last financial year *amounted to over* £4,000, including panel of 3,300 and appts. producing £2,500. Third share offered to commence with, with prospect up to one half. Visits 5/6 to 10/6. Suitable house obtainable. Premium 2 years' purchase. Short preliminary assistantship offered.
20. *PARTNERSHIP.—CHESHIRE.—Within a few miles of a large town. —In a pleasant residential district* (pop. over 7,000), *the half share* of a very old-estab. Practice worth about £4,000 p.a. Patients all classes. Suitable house available on rental. Premium 2 years' purchase, part by instalments. Good society and schools.
21. *SOUTH MIDLANDS.*—FAVOURITE RESIDENTIAL TOWN.—PARTNERSHIP.—A one-fifth share in a very old-estab. good mixed-class non-dispensing Practice. Income last year over £5,000, and very rapidly increasing. Panel of 1,700. Fees 5/- to 10/6. Suitable house available. Excellent schools, sport, and social life. Premium £2,000.
22. *LARGE HOSPITAL TOWN, within 50 miles of London.*—PARTNERSHIP.—A one-fifth share, to commence with, in well-established mixed general Practice. Income about £8,000, including large panel. Fees 5/6 to 21/-. Good house available, with large garden. Price £2,800, *large part on mortgage.* Premium 2 years' purchase, £2,000 down and balance by instalments. As there is unlimited scope for surgery, purchaser must have an F.R.C.S.
23. SOMERSET.—Near Hospital Town, in very pleasant residential district, an old established *unopposed Country PRACTICE* averaging over £900 p.a., *including panel (producing about* £400 p.a., *with mileage)* and appts. Visits 5/6 to 21/-. Railway station in place. Nice house (5 bedrooms, dressing and bathroom, etc., garden). Price, freehold, £1,500, of which £1,000 on mortgage. Premium £1,400.
24. LONDON, EAST.—(*Within 1 mile of Liverpool Street*).—*Old-established* PRACTICE in thickly populated district worth last year £848, including panel of 520. Small house (surgery, waiting room, dispensary, lounge sitting room, 2 bedrooms, bathroom, etc.). Rent on lease £60 p.a. Premium £1,400, or near offer, to include fitted carpets, linoleum, and curtains.
25. LONDON, S.W.—Well-established non-panel PRACTICE. Income last year £850. Visits 5/- to 21/-. *Accommodation* suitable for single man (or married without family), or could be worked as "Lock-up." Premium £1,000, *or near offer. Ill health reason for sale.*
26. MANCHESTER.—Rapidly growing Suburb within 5 miles of the City.—Old-established mainly middle-class PRACTICE, producing a steady average income of £2,000. Panel of nearly 1,400. Fees 3/6 to 10/6. Large house and garden. Price, freehold, £2,500, or would be let on lease at £120 p.a. Premium £3,500.
27. SUSSEX.—PARTNERSHIP.—A one-half share in a very old-established unopposed Practice in delightful district *near* sea. Average cash receipts for past three years £2,800, including £1,000 from panel and appointments. *Visits 3/6 to 42/-. Midwifery from* 2 gns., about 30 cases. Very attractive house, 2 reception, 5 bedrooms, etc. Large garden. Can be rented on lease at £80 p.a. Prem. 2 years' purchase.
28. PARTNERSHIP.—Pleasant Seaside Resort within 40 miles of London.—A third Partner *required* in very *old-established* mixed-class Practice worth about £5,000 p.a. (this year it is anticipated receipts will be £5,500), including panel about 1,800. Visits 5/- to £1 1s. Only 20 to 30 midwifery cases yearly. Prospect of being appointed on Hospital staff *within reasonable time. Suitable flat* available or house to be obtained. Premium 2 years' purchase.
29. PARTNERSHIP. — WITHIN 50 MILES OF LONDON. — A fourth Partner is required to take over a *share*, representing about £1,300 p.a., in an exceptionally sound good middle-class Practice situated in attractive *residential* district. *Panel of over* £3,500. Nice house, with 3 reception, 5 bedrooms, *etc.* Garden. Garage. Rent £60 p.a. on lease. Good sport and schools. Premium 2 years' purchase, *part* by instalments.
30. *PARTNERSHIP.—NORTH WALES.*—(Pretty district on Borders of Cheshire).—The THIRD or HALF *SHARE of old-established* PRACTICE worth over £4,000 p.a., and consisting mainly of panel *(producing* over £2,100) and appts. worth about £1,600. Expenses light. Suitable house available if half share taken (net rent £50 p.a.), otherwise inexpensive rooms. *Premium for share 14 years'* purchase.
31. SUFFOLK.—COUNTRY PRACTICE, near sea.—One-third share in good mixed class Practice averaging about £3 300 p.a., including panel of 1 300 Suitable house available. Premium 2 years' purchase. Preliminary *assistantship* essential.

Full Schedule of Terms and Conditions will be forwarded on application.

When the Colon Bacilli Revolt



WHEN the normally non-pathogenic colon bacilli rebel under the influence of foreign invaders or because of the putrefaction and toxæmia resulting from constipation and fæcal impaction, the consequences may be grave in the extreme.

The logical treatment is obviously preventive. In all cases of chronic constipation, incipient stasis or fæcal impaction, and in certain forms of intestinal toxæmia, prompt and efficient evacuation, followed by gradual resumption of normal bowel action, will be obtained by the use of AGAROL Brand Compound, *the original agar-agar emulsion.*

A generous trial quantity sent on request

FRANCIS NEWBERY & SONS, LTD.

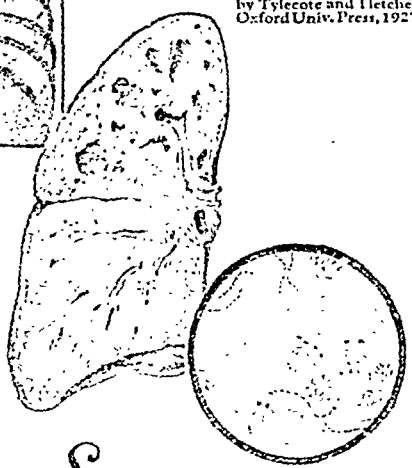
"As we have no recognized means of directly curing pneumonia, our treatment must be based on general principles, and is largely symptomatic. All through the illness we should remember the supreme importance of protecting the heart. . . . *The pain of the initial pleurisy may be treated by hot applications of Antiphlogistine.*"

"Diagnosis and Treatment in Diseases of the Lungs"
by Tylecote and Fletcher.
Oxford Univ. Press, 1927.

for
the pain
of the
initial pleurisy in
the pneumonias—
Antiphlogistine



is unrivaled. To the Medical Profession the world over, the name Antiphlogistine means far more than a poultice. From its very inception, in fact, Antiphlogistine has always been universally recognized as synonymous with the prompt suppression of pain—both superficial and deep-seated.

SPREAD at the onset—*not as a last straw*—but at the very onset of a suspected pneumonia, Antiphlogistine has in countless numbers of cases shortened the period of the attack and erased much of the suffering and pain. Many leading medical authorities acclaim this topical measure as the *sine qua non* for the successful management of pleurisy and the pneumonias.

THE DENVER CHEMICAL MFG. CO., LONDON, E.3

You may send me, free of all charges, your illustrated brochure, "The Pneumonic Lung," together with sample of Antiphlogistine for clinical trial.

J. & A. CHURCHILL

For Christmas Presents

86th Annual Issue. 2,300 pages. 54,000 names. 14 Pictures of Spas. **36s.** net, postage 1s.

The MEDICAL DIRECTORY, 1930

Including the BRITISH HEALTH RESORTS SECTION, Edited by **R. FORTESCUE FOX**, M.D.

THE RECENT ADVANCES SERIES

The Latest Volumes are **PREVENTIVE MEDICINE**, by J. F. C. HASLAM, M.C., M.D., 25 Illustrations, **12s. 6d.**, *Ready Jan., 1930;* **PLANT PHYSIOLOGY**, by E. BARTON-WRIGHT, M.Sc., 51 Illustrations, **12s. 6d.**, *Ready Jan., 1930;* and a FIFTH EDITION of **MEDICINE**, by G. E. BEAUMONT and E. C. DODDS, M.V.O., 49 Illustrations, **12s. 6d.**, *Published Oct., 1929.*

SURGERY

By W. H. OGILVIE, F.R.C.S. 2nd Edition. 115 Illustrations. 15s.

"The author has succeeded in writing a clear, concise, and systematic account of the latest work in all branches of surgery."—THE LANCET.

OPHTHALMOLOGY

By W. S. DUKE-ELDER, F.R.C.S., M.D., D.Sc. 2nd Edition. 4 Col. Plates; 110 Figs. 12s. 6d.

"The issue of a second edition within eighteen months is a certain indication that it has met a need. . . . Mr. Duke-Elder has set himself a high standard, and the second edition fully maintains it."—BRITISH MEDICAL JOURNAL.

DISEASES OF CHILDREN

By W. J. PEARSON, D.S.O., D.M., and W. G. WYLLIE, M.D. 18 Plates; 32 Figs. 15s.

"It should certainly be read by those interested in modern medicine . . . a familiar subject approached on unusual lines."—BRITISH MEDICAL JOURNAL.

TROPICAL MEDICINE

By Sir LEONARD ROGERS, C.I.E., M.D., F.R.C.P., F.R.C.S., F.R.S. 2nd Edition. 16 Illus. 12s. 6d.

"Will be read with great pleasure and profit by every medical man who wishes to handle his cases of tropical disease with efficiency; it will also be essential for constant reference regarding the doubts and difficulties which arise in everyday practice."—INDIAN MEDICAL GAZETTE.

BACTERIOLOGY

By J. H. DIBLE, M.B. Illustrations. 12s. 6d.

"Professor Dible has accomplished a difficult task. . . . He has made the story interesting and readable to everyone. . . . The reader is presented with a very comprehensive account of what has been done in the field of Bacteriology during the years since the commencement of the war to 1928."—BRITISH MEDICAL JOURNAL.

OBSTETRICS AND GYNÆCOLOGY

By ALECK W. BOURNE, M.B., F.R.C.S. 2nd Edition. 67 Illustrations. 12s. 6d.

"It ought to find its way into the library of everyone who is engaged in obstetrical and gynæcological work."—BRITISH MEDICAL JOURNAL.

PULMONARY TUBERCULOSIS

By L. S. T. BURRELL, M.D., F.R.C.P. 32 Plates and 17 Text-Figures. 12s. 6d.

"Most successful and will be read with profit, not only by those who are specially interested in diseases of the chest."—THE LANCET.

"There is no excuse for its absence from the bookshelves of even the busiest of practitioners."—BRITISH MEDICAL JOURN.

BIOCHEMISTRY

By J. PRYDE, M.Sc. 2nd Edition. 38 Illustrations. 12s. 6d.

"This compact work, which covers a wide field in an admirably balanced manner, should certainly be extremely popular with those members of the profession who wish to keep abreast of modern knowledge."—BRITISH MEDICAL JOURNAL.

ANATOMY

By H. WOOLLARD, M.D., B.S. 4 Colour Plates and 73 Figures. 12s. 6d.

"There is much information in this book which will, we think, be new even to some anatomists, and its success is certain. The book is of handy size, well printed, and clearly illustrated, and a good member of an excellent series."—THE LANCET.

PHYSIOLOGY

By C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S. 3rd Edition. 86 Illustrations. 12s. 6d.

"A most interesting book, and can be thoroughly recommended to all interested in the subject of physiology."—NATURE.

HAEMATOLOGY

By A. PINEY, M.D. 2nd Edition. 4 Coloured Plates and 18 Figures. 12s. 6d.

"A survey of recent developments in our knowledge of the blood and the diseases of blood-forming organs. Admirably and clearly written."—JOURNAL OF CANCER RESEARCH.

PSYCHIATRY

By H. DEVINE, O.B.E., M.D., F.R.C.P. 4 Illustrations. 12s. 6d.

"Dr. Devine has carried out what proved to be a very difficult task with extraordinary thoroughness, and is to be congratulated on a very fine piece of work. . . . The book will remain a standard record of progress in a branch of medicine which is all too frequently adversely criticised by the public."—NATURE.

CARDIOLOGY

By C. F. T. EAST, M.D., F.R.C.P., and C. W. C. BAIN, M.C., M.B. 12 Plates and 57 Text-Figures. 12s. 6d.

"This admirable volume, which in spite of very considerable inherent difficulties, which demand some courage to tackle, the authors have provided."—THE PRACTITIONER.

NEUROLOGY

By W. RUSSELL BRAIN, M.D., and E. B. STRAUSS, B.M. 38 Illustrations. 12s. 6d.

"The authors are to be congratulated on a thoroughly creditable presentation of a difficult subject, with a well-balanced discussion of opposing views."—BRIT. MED. JOURN.

NOW READY. With many Illustrations. 42s., postage 1s.

A CHEMICAL DICTIONARY

By INGO W. D. HACKH, Professor of Chemistry, College of Physicians and Surgeons of San Francisco, California.

London: 40, Gloucester Place, Portman Square, W.1

THE EXTRA PHARMACOPŒIA

By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition.

Vol. I, 27/6 net; postage 6d.
Vol. II, 22/6 net; postage 4d.
Complete Work (2 Volumes) 50/- net, post free.

In Two Volumes.

Vol. I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.
Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: "*Has a well-established reputation as a most useful and convenient work of reference.*"
LANCET, Nov. 2nd, 1929, says: "*A clear and authoritative publication of the highest value.*"

An up-to-date Book for everything on the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and numerous other subjects

LONDON: H. K. LEWIS & CO. LTD., 136, Gower Street, W.C.1

Live cultures for the treatment of constipation, intestinal putrefaction, etc.

CULTURE MEDIA

Issued in tube and in bulk.

Address enquiries to the Secretary, 6, HARLEY STREET, LONDON, W.1.

BAILLIÈRE, TINDALL & COX'S
RECENT PUBLICATIONS.

NOW READY. NINTH EDITION, ENLARGED AND THOROUGHLY REVISED.

PATHOGENIC MICROÖRGANISMS: A PRACTICAL MANUAL FOR STUDENTS, PHYSICIANS, AND HEALTH OFFICERS.

By W. H. PARK, M.D., Professor of Bacteriology and Hygiene, University and Bellevue Hospital Medical College, and Director of the Bureau of Laboratories of the Department of Health, New York City; and A. W. WILLIAMS, M.D., Assistant Director of the Bureau of Laboratories of the Department of Health.

Size 9¼ × 6. With 216 Engravings and 9 Full-page Plates. Price 30s. Postage 1s.

CLINICAL LABORATORY DIAGNOSIS

By C. C. BASS and FOSTER M. JOHNS, Department of Experimental Medicine, Tulane Univ. Med. School.

¶ "*We do not recall any recent publication which in so marked a degree responds to what is a real need of the general practitioner, or for the matter of that the consultant wishing to avail himself of the knowledge to be gained from clinical laboratory investigations. A very reliable guide to clinical laboratory methods which the keen practitioner should add to his library.*"—MEDICAL OFFICER.

Third Edition. Size 6 × 9. Pp. xviii + 190, with 125 Illustrations and 20 Plates. Price 34s. Postage 9d.

MACKENNA'S DISEASES OF THE SKIN

¶ "*The second edition of this text-book ranks it as one of the best on skin diseases to be obtained at the present day. The inclusion of 36 coloured illustrations, and of the more recent methods of treatment of various diseases, mark the chief features of the new volume. . . . An essentially sound book.*"—ST. BARTHOLOMEW'S HOSPITAL JOURNAL.

Second Edition. Size 10 × 6½. Pp. xii + 452, with 36 Col. Plates and 143 other Original Illus. Price 25s. net.

SERUM DIAGNOSIS BY COMPLEMENT FIXATION

By JOHN A. KOLMER, M.S., M.D., Dr.P.H., D.Sc., LL.D., Prof. of Path. and Bact. in the Graduate School of Med. of the Univ. of Pennsylvania.

¶ "*Professor Kolmer's experience of complement fixation must be immense, and in his latest book he has given a masterly and lucid survey of its principles and technique, no detail being too small for consideration . . . a really valuable addition to the already voluminous literature on the subject.*"—THE LANCET.

9¼ × 5¾. Pp. vii + 583. 65 Figs. Price 31s. 6d. Postage 1s.

PHYSIOTHERAPY IN GENERAL PRACTICE

By E. BELLIS CLAYTON, M.B., B.Ch.(Cantab.), Director of the Physiotherapeutic Department at and in charge of the Massage and Electrical School, King's College Hospital, London.

¶ "*A book which should prove of great value to the general practitioner.*"—GLASGOW MEDICAL JOURNAL.

Second Edition. Pp. x + 231, with 9 Plates and 30 Illustrations. Price 12s. 6d. Postage 8d.

DIABETIC SURGERY

By LELAND S. McKITTRICK, M.D., F.A.C.S., Surgeon to Out-patients, Massachusetts General Hospital; and HOWARD F. ROOT, M.D., Assistant Physician, New England Deaconess Hospital.

Size 9 × 5½. Pp. xii + 270. With 2 Coloured Plates and 79 other Illustrations. Price 21s. Postage 8d.

BACTERIOLOGY: General, Pathological, and Intestinal

By A. J. KENDALL, B.S., Ph.D., Dr.P.H., Prof. of Res. Bact. in the Northwestern Univ. Medical School, Chicago, Ill.

¶ "*The specific pathogeny of bacteria and the methods for their detection are described amply, yet concisely; the book is thus not only a digest of present-day bacteriology, but an invaluable laboratory manual.*"—BRITISH MEDICAL JOURNAL.

Third Edition, thoroughly revised. 9¼ × 5¾. 103 Figs. 8 Plates. Pp. 733. Price 31s. 6d.

WORTH'S SQUINT: Causes, Pathology, and Treatment

¶ "*Original, full of ideas, and rich in useful diagnostic and therapeutic points.*"—ARCHIVES OF OPHTHALMOLOGY.

Sixth Edition. Size 9 × 6. Pp. x + 242, with 42 Illustrations. Price 10s. 6d. Postage 9d.

HABITUAL CONSTIPATION and ITS TREATMENT

An Account of a New Therapeutic Method

By M. H. BURNIER, M.D.Lausanne, M.R.C.S.Eng., L.R.C.P.Lond.

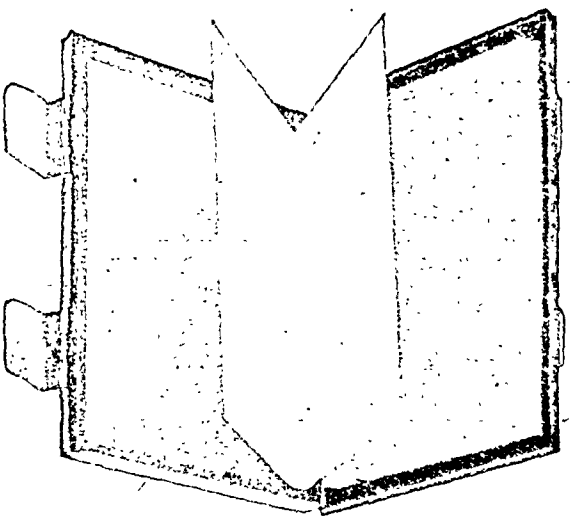
¶ "*This is a useful monograph written with the view of introducing a new method of applying internal massage to the rectum. Chronic constipation is such a bane that the author's suggestions are well worth a trial.*"—MEDICAL OFFICER.

Pp. x + 70. Price 3s. 6d. Postage 3d.

7 & 8, Henrietta Street, Covent Garden, London, W.C.2.

"Kodak"

Metal X-Ray Cassette

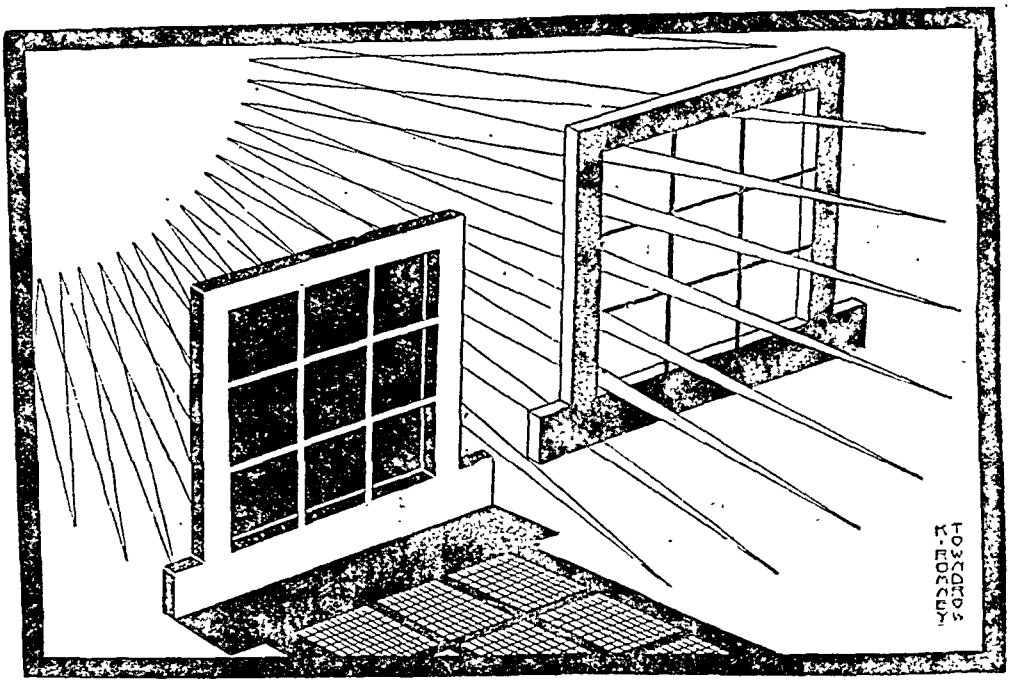


Simple and efficient.

The convenient book-form and absence of heavy back spring makes loading and unloading exceedingly simple.

Effective contact is ensured.

Kodak Limited (Medical Dept.)
Kingsway, London, W.C.2.



NO "VITA" GLASS WINDOW EVER GROWS UNHEALTHY.

In Towns or Country all the year round the ultra-violet rays of daylight can stream unchecked through windows glazed with "Vita" Glass. They continue to do so in perpetuity for "Vita" Glass is permanently health-admitting.

After a short period of exposure to daylight, "Vita" Glass experiences certain chemical changes common to all glass; it becomes "seasoned" and its power of transmitting the ultra-violet rays is thereafter stabilised; and it will not ever depart.

To-day "Vita" Glass is inexpensive. A large window measuring, say, 8ft. by 5ft. can have sheet "Vita" Glass for as little as £4, plus the cost of fixing.

"Vita" Glass was invented by British science and is the only glass of its kind produced by British Industry.

Medical Officers and all others interested in National health problems are invited to write for further information and prices from: THE "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders

health through your windows

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens

ENSURE THAT YOUR SUN-RAY TREATMENT PATIENTS CONTINUE TO **LIVE** IN AN **ULTRA-VIOLET RAY** ATMOSPHERE

Holviglass has been proved by scientific and practical experience to be an ideal medium for bringing the rays indoors from sun or sky. It is the most scientific and perfect "health glass" made, and is fully guaranteed by Holophane Ltd., illuminating engineers and experts in scientific glass-making for over 30 years.

Important sanatorium authorities have equipped extensive roof gardens with ultra-violet ray glass, so that patients continue their post-clinical treatment by living in an atmosphere of U.V.R.

Sanatorium, Clinical, and Hospital authorities are invited to consult Holophane Limited as to the comparatively small cost at which wards and conservatories, housing sun-ray patients, can be equipped.

Guaranteed HOLVIGLASS is supplied in sheet and cathedral form at a fractional additional cost of ordinary glass, through Builders, Glaziers, and Glass Merchants everywhere.

Fully descriptive Illustrated Brochure A63 and prices sent free on application

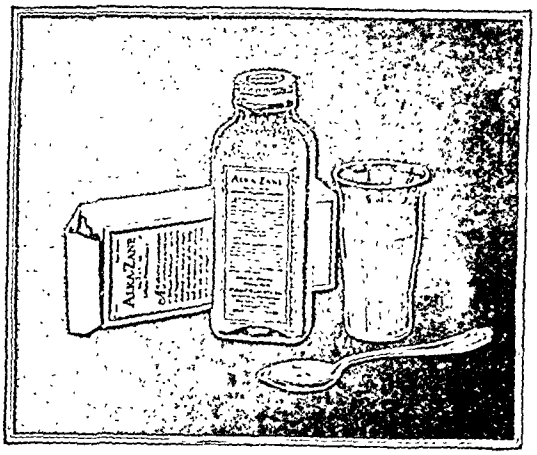
Decrease of the "Alkali Reserve"



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium.

is directly responsible for a large proportion of those ills which are manifestations of hyperacidity. Effective alkaline treatment is imperative. Alka-Zane, antacid and diuretic, promptly neutralizes the excessive acid products and rapidly restores the normal alkalinity of the blood.

A brief trial will demonstrate the efficiency of

ALKA-ZANE

Literature and samples to physicians on request.

Francis Newbery & Sons, Ltd.,
31-33, Banner Street, London, E.C.1.

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856.

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

Nujol

ERYTHEMA PERNIO

(Chilblains)

THE examination of tissue under the microscope in cases of Erythema Pernio provides ample confirmation of the widely held opinion that the origin and development of the condition is due to imperfect structure, or increased permeability, of the walls of the superficial blood-vessels. The exposure of the extremities to cold certainly aids the infiltration of the tissues, but the true underlying cause can best be described as a defective innervation or physiological condition of the vessel walls.

Calcium-sodium-lactate (Wulfing) i.e., Kalzana, is successful in the treatment of Erythema Pernio because, in its manufacture, the principles upon which calcium retention depends receive first consideration. The most important factor in the establishment and maintenance of blood alkalinity in man is the oxidization of the alkaline salts of organic acids, and this is definitely influenced by the sodium lactate element of Kalzana. Consequently the blood is able to retain the calcium constituent and use it for the relief of chilblains, or any other morbid manifestation of calcium deficiency.

Kalzana has been very successful in three cases of patients suffering from severe chilblains. I began the treatment at the end of October, and my patients were particularly free from them through the winter. ——M.R.C.S., F.R.C.P.

Dispensed by Chemists in air-tight packets containing 50 and 100 plain tablets.

OVALTINE

PHOSPHORUS IN NEURASTHENIA

Although it is realized that much difference of opinion prevails in medical circles as regards the therapeutic value of phosphorus, it is not illogical to claim that where the element is indicated, as in the neurasthenias, its tonic and restorative effects are more likely to be produced from natural phosphorus nutrients, such as those in "Ovaltine," than from medicinal products.

In the majority of cases in which "Ovaltine" has been prescribed for its "phosphorus" effect—that is, for its tonic and restorative effect upon the nervous system—the results of its administration have been gratifying in the extreme.

"Ovaltine" has been used with marked success in neurasthenia of the type known as cerebral neurasthenia, or psychasthenia, a variety of which is induced by excessive mental labour, or by worry, anxiety, or nervous strain.

The delicious flavour of "Ovaltine" renders the product acceptable even to the most fickle or jaded palate, while its exceptional nourishing qualities exert a profound influence for good health.

A liberal supply for clinical trial sent free on request.

Servant of a high official bearing offerings to the Tomb

BY APPOINTMENT

FIRST PERFECTED NEARLY A CENTURY AGO THEY HAVE GAINED INCREASING FAME EVER SINCE

ORIGINATED nearly a century ago by Mr. Brand and one of the most famous doctors of the day, Brand's Essences have steadily grown in fame.

Under scrupulous supervision and by an exclusive process, the juices of freshly killed chickens, beef and mutton are extracted. These pure juices without adulteration or addition of any kind are the essences that reach the consumer—full of the restorative and stimulating properties of the fresh meat.

For Brand's Essences have a stimulating action on the digestive organs. They excite the appetite and in all cases of exhaustion and during convalescence help the patient to want more solid food.

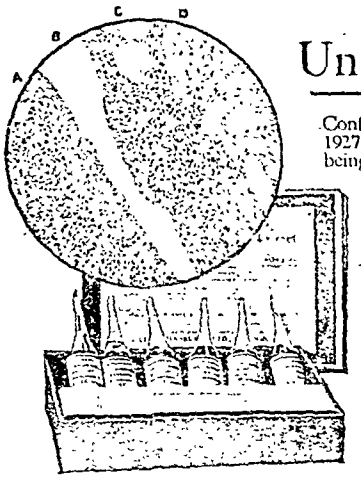
Brand's Essences (Beef, Chicken and Mutton) are obtainable at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Company Limited, Mayfair Works, South Lambeth Road, S.W.8.

BRAND'S ESSENCES

Trade 'PITIBULIN' Mark

Denotes

Unvarying Pituitary Extract



Conforming to the requirements of the Therapeutic Substances Regulations, 1927, 'Pitibulin' is prepared according to the official standards, its activity being now expressed in terms of the accepted unit.

As heretofore, 'Pitibulin' maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

'Pitibulin' retains its reputation as the Pituitary Extract which can be relied on in emergency.

Micro-photograph of section of Pituitary showing

(A) pars anterior
(B) inter-glandular cleft
(C) pars intermedia (posterior lobe)
(D) pars nervosa (posterior lobe)

'Pitibulin' is supplied in Ampoules containing 2.5, 5, and 10 units.

Literature giving fuller particulars of the therapeutic applications of 'Pitibulin' will be sent on request.

CAPROKOL

The Urinary Antiseptic for Oral Administration

Caprokol exerts an analgesic action upon the urinary mucosa and a continuous germicidal action in the urine.

The effects of a course of Caprokol treatment, therefore, are—

(1) Relief of the patient from the painful symptoms usually associated with urinary infections (this often takes place with astonishing rapidity).

(2) The destruction of the invading organisms, resulting, in most cases, in the complete sterilisation of the urinary tract.

IN TABLET FORM *ITS USE DOES NOT LEAD TO HABIT*

Laboratories: **LOBICA**, *46, Avenue des Ternes, PARIS (17e)*

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For *many years it has been successfully used* by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

R AND C

Indicated in the treatment of

all the gonadal dysfunctions of men and women

Sex gland deficiencies in men and women are successfully treated with Ovacoids, Testacoids and Ampacoids.

Each OVACOID contains:—

Autacoids representing Fresh Ovary ... ... 5 grs.
Autacoids representing Fresh Anterior Pituitary ... ½-gr.
Indications:—Sex gland deficiencies in the female, such as Amenorrhoea, Dysmenorrhoea, Menorrhagia, Sterility, Chlorosis, Frigidity, Sexual Neurasthenia, Hypertension and Functional or Artificial Menopause. Bottles of 50 Tablets.

AMPACOIDS

Ampacoids aqueous solutions for hypodermatic injection of the autacoids of Ovary, Testicle, and Prostate respectively.
They are physiologically standardized, and are free from all the contaminating substances present in ordinary gland extracts. Boxes of 6 l.c.c. Ampoules.

Samples and Literature from Sole Agents for United Kingdom and Irish Free State:—Coates & Cooper, 41, Great Tower Street, E.C.3.

Each TESTACOID contains:—

Autacoids representing Fresh Testicle ... ... 25 grs
Autacoids representing Fresh Prostate ... ... 5 grs.
Indications:—Sex gland deficiencies in the male, such as Sexual Neurasthenia, Premature Senility, Diminished Potency, the Male Climacteric, and whenever Sexual Stimulation is sought. Bottles of 50 tablets.

VITAD PALATINOIDS

¶ VITAD is the unsaponifiable fraction of Cod-Liver Oil containing in a high concentration Vitamins A and D.

¶ While presenting practically the full medicinal properties of Cod-Liver Oil, it is free from the nauseating oily fraction. Being exhibited as a Palatinoid, it is protected by the hermetically sealed non-actinic covering from all chance of oxidation and light action, thus ensuring a standard dose at all times.

¶ Palatinoid Vitad is put up in bottles of 25 and 100, and in two strengths:

m. 1½ for Children
m. 3 for Adults.

Two palatinoids respectively represent the full daily dose of Vitamins A and D.

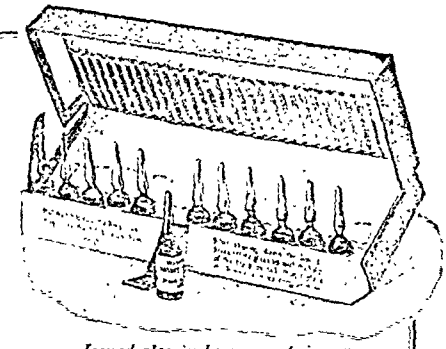
Manufacturers of Roboleine.

Pituitary
(Posterior Lobe)
Extract
B.D.H.



Issued also in boxes containing 100 ampoules specially for hospital use

A Genuine British Product

With the advance of endocrine treatment and with the consequent wider use in medicine of organo-therapeutic products, it has become a matter of particular urgency for the physician to employ only those products which he knows to be thoroughly reliable; it is not feasible in actual practice for the physician himself to test the relative potencies of different reparations—he must confine the material in his armamentarium to that issued by manufacturers whose products are known to be of an unassailably high standard.

Pituitary (Posterior Lobe) Extract B.D.H. comes within this category, and physicians employing it can do so with full confidence. It is doubly standardised—for the pressor action and for the effect in contracting uterine muscle.

Local Anæsthesia in Surgical Practice

UNUNITED FRACTURE.

TYPICAL CASE.

V. F., aged 55 years.

Diagnosis: Ununited fracture of neck of left femur.

Operation: Open operation and bone pegging.

Anæsthesia: Local infiltration, 120 c.c. of a 0.5 per cent. Novocain-Adrenaline solution.

History: Seven months before entering the Hospital, patient fractured the neck of the left femur while at work in a mill.

Operation: Direct infiltration was made, about 120 c.c. of a 0.5 per cent. solution being used. The hip-joint was exposed, the fractured surfaces freshened, and two beef-bone pegs were inserted through drill holes. The incision was closed and a plaster spica applied. The patient went through the operation without pain and co-operated with us while the plaster cast was being applied. Staphylococcus infection followed the operation but did not greatly delay convalescence.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Elixir of

ENZYMES

Elixir of Enzymes is a palatable preparation of the proteolytic and curdling ferments that act in acid medium. It is recommended as an aid to digestion and as a stomachic stimulant and mild carminative.

Elixir of Enzymes is of especial service in correcting faulty protein digestion which is one of the principal causes of gastro-intestinal auto-intoxication.

Elixir of Enzymes is an excellent vehicle for exhibiting iodides, bromides, salicylates and other drugs that disturb the digestive functions. One dram of Elixir of Enzymes will carry 46 grains of potassium iodide or 45 grains of sodium salicylate or 17 grains of potassium bromide.

PUERPERAL SEPTICAEMIA

It is now generally recognised, and has been again recently stressed by gynaecologists, that the principal causative agent in Puerperal Septicaemia is the Streptococcus Haemolyticus.

It is an interesting and important fact that Monsol, which is well known to have a selective action on Gram-positive organisms, has a particularly selective action on the strain Haemolyticus among the Streptococci.

The following table showing the relative dilutions at which Monsol is effective illustrates this.

STRAINS OF STREPTOCOCCI

DESIGNATION OF STRAIN	*SOURCE*	*DILUTION OF MONSOL*
"Diphtheritic"	Throat	1-100
Salivarius. Barnes 445	Mouth-Tonsillitis	1-100
Erysipelatis. 226	Lesion	1-150
Enterococcus Tissier 775	Faeces	1-150
Urine 8213	Urine	1-150
Rheumaticus. Beattie	Joint	1-300
Sputum A	Unresolved pneumonia	1-700
Sputum B	Unresolved pneumonia	1-700
Viridans 1080	Tonsil	1-1000
HAEMOLYTICUS 2060	—	*1-1500*
HAEMOLYTICUS B.C. 1498	—	*1-1500*
Mastitidis 2470	Mastitis	1-1500
Scarlatinae. Sherman 1892	Scarlet Fever	1-1500

The use of Monsol in obstetrics is, therefore, specially indicated owing to its selective germicidal power; while its non-irritant action on the most delicate mucous membranes and tissues, renders possible its use at dilutions far stronger than are germicidally necessary.

"SMILER"

HUMAN TUBERCULOSIS OF BOVINE ORIGIN

At the recent B.M.A. Conference held in Manchester reference was made to this important subject, of which the following abstracts (Lancet, Oct. 19, 1929, p 824) are typical:—

"Dr. ———, M O.H., in opening the discussion, estimated the human deaths caused annually by the bovine tubercle bacillus at 2,000 to 2,300. Most of them were the deaths of children, and we had no knowledge as to how many non-fatal infections occurred. As to the extent of bovine tuberculosis among cattle in this country, he thought that about 40 per cent. of the cows were infected; that about 1 per cent. of the cows were 'open' cases; and that about 0·3 per cent. had tuberculosis of the udder."

"Dr. ———, M.O.H., thought that 5 per cent. of the cows had diagnosable tuberculosis. He had found certified milk highly infected with tubercle bacilli. The graded milks were a failure, and pasteurisation was only doubtfully safe. He believed that milk dried by the roller process was the best solution, and he looked forward to the establishment of milk-drying factories throughout the country."

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

This annual toll of human life, which is mostly confined to young babies, can be eliminated by a suitable heat treatment of the milk. Processes such as pasteurisation have their limitations so far as the feeding of infants is concerned, particularly in view of their disturbing influence on the mineral and vitamin content of milk.

The bacteriological sterilisation of milk is assured by the COW & GATE Improved Roller Process, which also effects maximum preservation of the vitamin content with minimum disturbance of the mineral salts.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

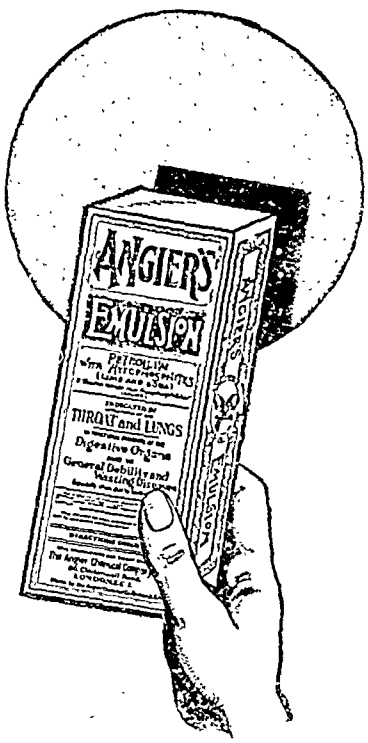
Bronchitis, Winter Cough,

Influenza and Sequelae.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration, and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases. Bronchial patients are nearly always pleased with Angier's Emulsion, and often comment upon its soothing, "comforting" effects.



The unique soothing properties of Angier's Emulsion, its favourable influence upon assimilation and nutrition, and its general tonic effects, make it eminently useful both during and after influenza. It has a well-established reputation for efficiency in relieving the troublesome laryngeal or tracheal cough, correcting the gastro-intestinal symptoms and combating the nervous depression and debility.

Benger's Food—*the adjustable diet.*

The "LANCET" describes it as "Mr. Benger's admirable preparation."

Owing to the presence of the natural enzymes of digestion (*Amylopsin* and *Trypsin*), and its method of preparation for a patient, the extent of self-digestion of Benger's Food and the milk with which it is mixed *can be regulated to suit the digestive powers of the patient.*

Benger's Food is prepared with fresh cows' milk. It forms a dainty cream which becomes the easier of digestion the longer it is allowed to stand after mixing. The process may be arrested at any time by simply bringing the mixture to the boil. (A useful average time for standing is 15 minutes).

Patients ordinarily unable to digest milk can take this mixture satisfactorily, as the Benger's food so softens the casein that when under the influence of the gastric juice it forms into minute flocculi instead of a heavy curd.

Benger's Food is of the highest nutrient value and is not found to pall, even when taken over long periods.

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

FRAGMENT OF UNDYED SILK FABRIC PRODUCED IN SHANTUNG AT THE END OF THE FIRST CENTURY, A.D.—The world is indebted to China for the knowledge of silk production. The export of silken fabric was chiefly responsible for the opening up of relations between China and the classical West, and incidentally with Central Asia and the near East, for the silken garments worn by wealthy Romans came from the looms of the Celestial Empire. The Emperor Wu-Ti was well advised to make the tremendous efforts he did to establish the permanent caravan trade, between China and Rome, which existed about 100 B.C. China, in her turn, imported glass, enamels, steel, pottery, elephants and horses. The long and arduous circuit absorbed about two years. Latin classical literature contains many references to the "Seres" or "silk-men" who brought their welcome wares to Rome. In addition to this evidence, we now have the strip of silk, excavated upon the actual route to the West, and here reproduced. Upon it are the words: "A roll of *lu-fu* silk from the kingdom of *Jen-Ch'êng*. Width, 2 ft. 2 in.; length, 40 ft.; weight, 25 oz.; value, 618 pieces of money." Jen-Ch'êng was the modern Chi-ning Chou in the province of Shantung.

STORIES OF FILIAL PIETY—THE PREMIER CHINESE VIRTUE—CARVED IN STONE.—Since filial piety may be said to lie at the root of the civilisation which has persisted in China for so many centuries, it is not surprising to find this virtue as the theme of a large number of her folk-tales. Three scenes of filial piety are represented in the relief here reproduced. Beginning on the right, Hing K'iu is *kneeling* and feeding his aged and toothless father with *food which* he has himself masticated for him. Behind him are *written* the words: "Hing K'iu, behaving towards his *father with* extreme filial piety," while above the old man is the *wording*: "The father of Hing K'iu in person." Further to the left Ting Lan is depicted kneeling before an unshapen mass of wood, explained by the words: "A man carved in wood constitutes a statue." Ting Lan made a statue of his late father, which he went to consult in a *difficult situation*, having placed before it a tray of offerings. The next figures represent

Min Tseu K'ien, his father, his wicked step-mother and her son. In driving his father's chariot Min Tseu K'ien let fall the whip from his frozen hands. His father, about to chastise him for his clumsiness, perceived that his step-mother had allowed him only the flimsiest of clothing in the depths of winter, whereas her own son was most warmly clad. In his indignation he now wished to kill his second wife. Min Tseu K'ien is here depicted interceding for her—his half brother having taken the *reins*. *Chinese* fables and folk-stories are found in different forms in many lands to-day.

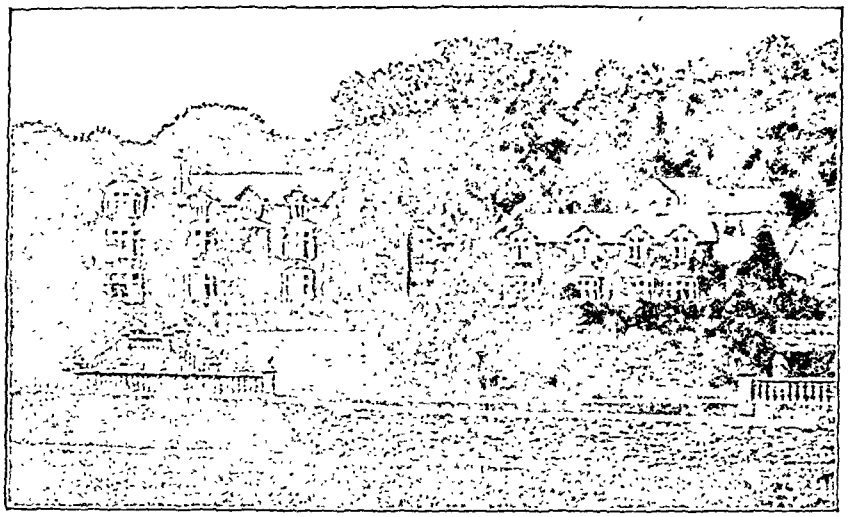
BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)



ARTHRITIS. AMBULATORY TREATMENT.

Mobility and freedom from pain in crippling arthritis of the hip and knee even after shortening and contracture have occurred.

This is the special achievement of BELLE VUE SPA; secured by Hoefftcke's extension appliances, which maintain continuous extension by night and by day.

The appliance permits the patient to walk, and not only takes the body weight but replaces the normal state of compression of the leg by one of active stretching.

There is no other satisfactory way of combining movement with extension.

The method secures:

1. Extension without muscle loss inevitable when the patient is kept in bed.
2. Extension without the vascular stasis which occurs when a joint is kept at rest,

AND MOVEMENT WITHOUT PAIN.

The result is rapid reconstruction of the joint with astounding restoration of function in those advanced cases which have hitherto seemed hopeless and incurable.

BELLE VUE SPA is well equipped for auxiliary treatment by massage, electricity, diet, light, etc , and full advantage is taken of the tonic virtues of its chalybeate waters.

The strongest pure ferrous iron waters in the world.
NOT CONSTIPATING.
FREE FROM FERRIC SALTS AND OTHER IMPURITIES.

Close co-operation maintained with the patient's own practitioner.

Physician: HUGH WILLIAMS, L.R.C.P., L.R.C.S.(Ed.).

Apply: **The Secretary, Belle Vue Spa, Trefriw, North Wales.**

Telegrams. BELLEVUE, TREFRIW. Telephone: LLANRWST 60.

PROPRIETORS: **AMBULATORY TREATMENT LTD.**

C. A. HOEFFTCKE, Managing Director, 7, Harley Street, London, W.1.

An Address
ON
ABORTION: ITS FREQUENCY AND IMPORTANCE.*

BY
BECKWITH WHITEHOUSE, M.S.Lond., F.R.C.S.,
PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN, UNIVERSITY OF BIRMINGHAM.

THE subject of this address has been chosen for two reasons—namely, its frequency, and its importance to the individual and the community. The increasing number of abortions amongst most white races during the past thirty years has naturally focused attention upon a problem which has always to some extent exercised the minds of the medical and legal professions. With a stationary or falling birth rate the position naturally becomes more acute, and the prevention of abortion is to-day a responsibility which involves not only the welfare of the individual but also that of the family and the State. A nation with a diminishing birth rate and a high abortion ratio must sooner or later suffer. There appears to be little doubt that, for the present, the day of the large family has gone, for good or for evil. We are told that it is for good, but sometimes I have my doubts on this matter. I know many large families, families of as many as ten or a dozen, and I say unhesitatingly that in my experience they are the happiest, and are getting the best out of life. I have spoken to the mothers of these families, mothers from all grades of society, and never once have I heard any expression of regret, either from a social, economic, or physical standpoint.

In this age of mechanical transport, unhealthy excitement, entertainment, and "rush," the modern cult for limitation of the family by the wholesale promulgation and practice of contraceptive measures is speeding apace. There are too many intentionally sterile marriages to-day, and perhaps, what is equally as bad, there are too many one-child families growing up. Abortion must therefore be regarded as something more than a trivial accident. Its frequency in some countries to-day is appalling. Gellhorn states that in Germany, in 1890, one abortion occurred to every ten births. In 1911 the proportion had dropped to one in five, and in 1919, in Hamburg, the figure had reached one in two. In 1926 two abortions occurred for every three births. In each year in Germany the actual number of abortions varies between 500,000 and 875,000. In Soviet Russia the artificial termination of pregnancy during the early months is actually legalized, and State "abortoriums" have been established.

In this country abortion at present is not notifiable, and consequently reliable statistics are not available. Even if notification were established it is doubtful whether the information obtained would be of real value. The attitude of the lay mind to the whole question of abortion varies tremendously. Nothing is more conveniently forgotten than the termination of an unwanted pregnancy. On the other hand, where such a pregnancy is desired, abortion is a disaster, and its recurrence a real tragedy. Between these two extremes are the number of "so-called" "slight abortions," casually remembered by some individuals, and as casually related, during the taking of a clinical history. These are the items which probably would be overlooked in any system of notification and which would falsify the records.

From such figures as are available in the case sheets of hospital records it is a satisfaction to find that in this country we are not at present faced with anything approaching the state of affairs which obtains in certain European areas to-day. Recently I analysed the incidence of abortion among 3,000 of my hospital and private patients, and found that the ratio of abortions to births was 1:4.7. In a total of 11,430 pregnancies the percentage of abortions was 17.2; and among the total 3,000 cases the percentage of women who had aborted at some time or other during their sexual life was 35.3. For purposes of comparison the cases were grouped into "pre-war" and "post-war" years, and it was interesting and pleasing to find that the proportion was almost the same. In the case of 1,208 pre-war patients the abortions among 6,021 pregnancies registered 17.7 per cent., and the ratio to births at term was 1:4.6. Among 1,148 post-war cases the percentage of abortion was 16.9, and the ratio of abortion to births 1:4.8. These figures are based upon information provided by women attending a gynaecological clinic for many different lesions, and of course are open to the criticism previously advanced that they under- rather than over-estimate the true position of affairs. In the case of the "private" group, it is known that they include certain abortions "procured" for various indications, and therefore they do not give any guide to the incidence of "natural" as opposed to "intentional" abortion.

The criminal practice of the artificial termination of pregnancy naturally vitiates the value of any series of figures which purport to ascertain the frequency and causation of natural abortion. We know that many procured abortions occur in the community, but it is a very difficult, in fact practically an impossible, task to obtain direct information upon the actual number. There are many cases of this nature where neither the services of a doctor nor those of a midwife are asked, and if no complication arises the event is probably soon forgotten. The chief offenders in this group are those married women in whom pregnancy is not desired or for whom it is inconvenient. During the last few years I have been approached by many more married than single women with the object, expressed or implied, of terminating a pregnancy. The reasons put forward are various: sometimes, but very rarely, it is on the ground of economy; more frequently because the previous confinement had been complicated or difficult and there was an honest fear to approach the risks of labour again.

Another group includes those women who become pregnant again late in life, when the other members of the family are growing up. More than one patient of this group has felt her position acutely, and has told me that she "could not go through the disgrace of having another child." These actual words demonstrate the peculiar attitude of mind of some individuals in dealing with what, after all, is a purely physiological function.

One fact has been impressed upon me time after time, and that is the pertinacity of the married woman who sets out with a determination to terminate her own pregnancy. Argument is useless, and when she has failed to produce the required result by means of a popular purgative pill or a prescription from a fashionable chemist "to remedy all female menstrual irregularities," she approaches her own doctor. If he finds no indication to interfere she goes to somebody else, and eventually possibly does find some individual who is able to satisfy his own conscience that a medical reason exists for the evacuation of the uterine contents. If help cannot be obtained in this devious manner there is always the homely knitting-needle, crochet-hook, douche nozzle, or the professional criminal abortionist. Women in this state will not listen to words of advice or warning. They are optimists of the first water, individuals who do not care what happens as long as it does not happen to themselves. I do not propose to say anything more on this question of criminal abortion. The subject has been discussed very fully recently by the Medico-Legal Society, the Society of Medical Officers of Health, and the Royal Society of Medicine, and I refer you to the Transactions of these societies for an expression of the considered and current views of those best qualified to speak.

A much more intriguing subject to the obstetrician, as distinct from the medico-legal expert, is the cause of natural abortion. Why is it that some women abort time after time and others never do so in spite of the application of those factors which are commonly regarded as provocative agents? When pregnancy is desired the occurrence of abortion is a great disappointment to a woman, and should the accident be repeated it is indeed regarded as a disaster. Most of us are familiar with cases of this type, and we know from experience how difficult it is in the

* Read before the Oxford Division of the British Medical Association at the Radcliffe Infirmary, Oxford, on October 23rd, 1929.

absence of definite pathological physical signs to advise our patients for the future. It is this aspect of abortion that I wish to consider more particularly to-day.

Syphilis and Abortion.

In the first place let me say a few words upon the relation of syphilis to abortion and premature birth. I think it may be said that syphilis is commonly regarded as being a cause of repeated miscarriage. For some years I have been a little doubtful about the truth of this assertion, and in order to obtain more definite information on the matter I approached Dr. Assinder, the officer in charge of the Government Venereal Department at the General Hospital, Birmingham. He very kindly instituted an inquiry for me upon 678 patients who had attended his clinic. The most important group concerns tertiary syphilis, for it is obvious that in the case of primary and secondary syphilis the disease had nothing to do with the abortions, the records having been made when the patient first presented herself. The miscarriages and stillbirths had happened in the past.

In the case of 493 tertiary syphilitics the percentage of abortions was 37·3, almost identical, in fact, with the figure of 35.3 which is the percentage of abortions from *all* causes. It cannot be said, therefore, that syphilis increases the predisposition to abort during the early months of pregnancy. If, however, the stillbirths are included, a further addition of 22.1 per cent. must be made, giving the high total of 59.4 per cent. In the case of 28 congenital syphilitics no abortions or miscarriages had occurred. These figures, therefore, tend to confirm my original view that syphilis is not so much a cause of abortion during the early months of pregnancy as of premature labour or stillbirth. It is after placentation is completed that the syphilitic virus exerts its chief effect, and produces those macroscopic and microscopic changes in the foetus, its umbilical cord and membranes, with which pathologists are familiar.

The Vitality of the Germ Cells.

Abortion of the products of gestation from the pregnant uterus is by no means a phenomenon confined to the human species. It happens in many domestic animals, and a study of the causes which lead to its occurrence in these lower types may throw light upon some of the *obscure* cases in human pathology.

Professor Arthur Robinson, working with *ferrets*, found that the germ cells of certain perfectly normal healthy animals are incompatible with the corresponding germ cells of other healthy animals of the opposite sex. The result is usually absolute sterility. In certain cases, however, there is evidence of death in the uterus of fertilized ova, which Robinson thinks may be due to this factor of incompatibility. Gestations in the ferret are usually multiple, and each pregnancy has a corresponding corpus luteum in the ovary. By a series of sections of the ovaries and uteri it is possible to correlate the corpora lutea and the pregnancies, and Professor Robinson has found that, in the same healthy animal, whilst some fertilized ova or zygotes develop in a normal manner, others from the same oestrus sometimes die and are absorbed. This occurs in the absence of any local lesion in the uterus, and therefore he attributes the death to *incompatibility* of the ovum and spermatozoon, or what may be termed a lack of inherent vitality of the germ cells. Abortion due to this cause may be regarded as caused by sexual inefficiency of either the male or female, or both.

Whether such incompatibility of certain or all of the sexual cells occurs in the *human species* it is difficult to say. There is no doubt that many women who have been sterile for some years abort once, twice, or even more times if, and when, pregnancy occurs. In an analysis of 1,233 patients, giving the relation of abortion to parity, I found that in a total of 336 childless women 265 were absolutely sterile and 71 aborted after they had become pregnant. Three had had four successive abortions, and two as many as five. Incompatibility may be the cause of these disasters, but proof can only be obtained when evidence is brought of the fertility of each individual with another partner.

Can defective vitality of the germ cells be acquired? This again is a question where it is impossible to be dogmatic about the answer. There is, however, some evidence indicating that the problem of abortion is sometimes associated with factors of heredity. The place of an individual in the family is certainly a point to be considered. Several cases of repeated and unexplained abortion have come under my notice where it has transpired that the patient is the last member of an exceptionally large family—a contraceptive experiment on the part of Nature. One such case I quote, as it appears to afford an excellent illustration of exhausted reproductive capacity.

Mrs. L., aged 33, married and sterile for five years, was delivered of a dead macerated child at the seventh month of her first gestation, no cause being assigned. The Wassermann reaction was *negative*. She is an undersized *individual*, weighing 7 st., and is herself a 7½ months child, the last of a family of thirteen. Her immediate brothers and sisters were all premature. Two were stillborn, one has a congenital cardiac lesion, and another *tuberculosis*. A *point of great interest is that* Mrs. L.'s own mother was also a premature child and the last of a family of sixteen.

As parity increases there is a progressive increase in the incidence of the number of *women who abort*. Failure of reproductive power may be a factor, but before this can be *proved information* must be *forthcoming* of the place of abortion in the list of pregnancies of exceptionally fertile women. It is, *of course*, a difficult matter upon which to obtain unequivocal data, for all kinds of extraneous influences are introduced as the number of pregnancies increases. I think, therefore, that more reliable facts can be collected, when available, by careful investigation of the family history, and especially of the place in the family of a given individual.

The Relation of the Decidua to Abortion.

The development and function of the uterine decidua call for special consideration in relation to abortion. The decidua is, of course, the highly developed endometrium peculiarly adapted for the reception and implantation of the fertilized ovum or zygote. It is now generally accepted that this thick fleshy structure which lines the pregnant uterus is but the fully developed phase of growth which is initiated immediately after each menstrual period, or menstrual abortion, as I prefer to call it. This progressive development is stimulated and maintained by a hormone elaborated first in the Graafian follicle and then in the corpus luteum when the oöcyte has left the former. If this hormone is withdrawn by destruction, excision, or even aspiration of the Graafian follicle or the corpus luteum, the decidua necroses. If the decidua is that of the unimpregnated uterus, then an artificial menstrual "period" is produced. On the other hand, if a fertilized ovum is embedded in the decidua, abortion naturally follows. This fact, originally demonstrated by Fränkel in Vienna, has since been confirmed by many observers.

Teal and Parkes have lately shown that lutein development is controlled by the anterior lobe of the pituitary gland. In rats it is possible by the administration of extracts of this gland to sensitize and stimulate the development of the endometrium to an extreme degree of decidual formation during the resting sexual phase. The production of these artificial placentomata depends upon abnormal luteinization of the ovaries by the pituitary extract. It is evident, then, that the normal development and function of the decidual organ are very complex phenomena, intimately associated with the physiology of the ovary and pituitary gland. These organs, and especially the ovary, assume, therefore, considerable importance in their relationship both to *normal* pregnancy and the causation of abortion.

There are many organic pathological conditions associated *with premature* death and expulsion of the uterine contents where lesions in the ovary may be contributing factors. In the case of uterine fibroids, and in retroversion of the uterus with prolapse of the ovaries, both Graafian follicles and corpora lutea frequently show patho*logical lesions*. Haemorrhage and Graafian and lutein haematomata are common, as well as the so-called theca-lutein cysts. Both uterine fibroids and *retroversion* are

associated on occasion with abortion, and it is conceivable that the deciding factor which kills the ovum and leads to the abortion is the lutein lesion which so often coexists. Cystic states of the corpus luteum have long been known to occur in relation with ectopic gestation and with vesicular mole, and I have had two opportunities of examining the ovaries in the case of carneous moles, where the same lesion was present.

It is, of course, possible that the ovarian lesions may be the result and not the cause of the death of an ovum. There is no information available as yet to show what happens to a corpus luteum when pregnancy is suddenly terminated at different stages of its development. Does it atrophy, degenerate, or become cystic? These are points which should be investigated, owing to the possibility of abortion producing a permanent lesion in the ovary.

Great strides have been made during the last few years with regard to ovarian and uterine physiology. New chapters have been written, and light has been thrown upon problems which were formerly obscure. There is still, however, much for us to learn. Take the matter of innervation of the ovaries and uterus. Why is it that mental or physical shock is sometimes followed by abortion? The decidua itself is not supplied by nerve elements, but the ovaries are very liberally supplied with both ganglia and nerve fibres. Sections of ovarian tissue stained by Bielschowsky's method show a highly complex system of nerve elements in relation to the Graafian follicles and capillary blood vessels in their immediate proximity. Abortion rarely follows immediately upon a nervous stimulus, but occurs usually a few days later, when presumably necrosis of the decidua has taken place. Does this mean that the corpus luteum has been inhibited in its function through the network of nerve plexuses and ganglia which surround it?

Turning to the endometrium itself, there is little doubt that its integrity and power to respond to sensitization by the lutein hormone are essential factors for the normal implantation and development of the zygote. If it is hypertrophic, as in the case of uteri the seat of fibromyomata or chronic subinvolution, or has been injured by repeated attacks of chronic inflammation, it responds to the lutein stimulus in a defective manner, with the result that the zygote develops in an abnormal environment. Curettings from uteri which have recently aborted frequently show an atrophic or poorly developed decidua, or a decidua which is infiltrated with inflammatory cells. It is reasonable to suppose that the physiological function of such a decidual organ is defective and that the interchange of food factors through the chorio-decidual space is also abnormal.

In the case of 300 women who gave a clinical history of three or more abortions, uterine lesions were present in 53.3 per cent.; and evidence of chronic inflammation in the pelvis, in relation with either the genital tract or pelvic peritoneum, occurred in 26.6 per cent. of the patients.

The Relation of Pathological Ova to Abortion.

Certain embryologists, notably His and more recently Mall, have drawn attention to the interesting fact that a very large proportion of human ova that are aborted are abnormal in some respects. The largest number of abortions occur during the second and third months of gestation, and Mall has stated that 50 per cent. of the ova that he has examined during this period are pathological. Many and varied are the types of abnormality that occur. In some the embryo consists merely of a nodule representing the umbilical vesicle. The amnion may or may not be present. Sometimes the chorion only exists. In others the embryo is destroyed after the development of the amnion and may be represented only by the stump of the umbilical cord. Spina bifida is common, as also is anencephalus. These pathological embryos, if they survive, produce monsters, and it is perhaps a satisfactory provision of Nature that the factors which cause the abnormality usually exert such a radical influence that the lesions are incompatible with further development. The ovum dies, becomes a foreign body, and as such is expelled by the uterus. As so large a proportion of abortions consist of pathological ova, the question has been raised by Mall as to whether it is justifiable to attempt to prolong a pregnancy when abortion is threatened before placentation of the ovum is complete. I cannot subscribe whole-heartedly to this view, as, of course, one knows of many early threatened abortions which have subsequently progressed normally and terminated with the birth of a normal and healthy child. At the same time, I can recall two instances when abortion was averted with considerable care, only to result in the birth later of children with spina bifida and anencephalus respectively.

My interest in the investigation of the uterine products of abortion was stimulated by association with the late Professor Peter Thomson, whose views coincided largely with those of Mall. The great majority of early abortions that fall into our hands are damaged by trauma and are useless for scientific investigation owing to rupture of the foetal membranes. With care, however, it is possible in the course of time to collect a certain amount of useful material, and such investigations as I have been able to make tend to confirm Mall's views on the high incidence of pathological ova among the products of abortion.

In these aborted ova lesions are not by any means confined to the embryo itself. Disease of the chorion frequently coexists. The most constant and the earliest evidence of a pathological state is the presence between the chorionic villi of a mucoid substance containing leucocytes. The syncytium grows into this mass in an irregular manner, and in some cases actually invades the mesoderm of the villi. The villi themselves vary considerably in their numbers and distribution. In some ova they are very scanty; in others they are irregularly scattered over the surface of the gestation sac; and in yet others they exhibit various signs of degeneration, as shown by mucoid, hyaline, or fibrous change.

Are these abnormal ova that are so commonly aborted the result of external influences, such as a diseased or abnormally functioning decidua, or are they caused by inherent pathological attributes in the germ cells? There is a diversity of opinion on this matter among embryologists, but the weight of evidence, I think, is in support of Mall, who considers that pathological forms are caused by external influences and not by anatomical or physiological defects in the ovum or spermatozoon. As he points out, one most important argument in support of the influence of environment is the fact that when the ovum is implanted in an abnormal position where the decidua is absent or defective—for example, the Fallopian tube—96 per cent. of the embryos are abnormal. This fact alone serves to emphasize the importance of a healthy and functioning decidua in the well-being of the developing ovum.

Another, and equally important, argument is that every type of abnormal embryo and monster known to occur in the human species can be produced in other organisms by artificial means from normal ova and embryos. Spina bifida can be produced in tadpoles by subjecting frog spawn to the action of common salt, a 0.7 per cent. solution giving 100 per cent. of this abnormality. Magnesium solutions have been used by Stockard to produce cyclopia in certain fishes, with 50 per cent. success. When sea-urchins' eggs are submitted to the action of lithium salts inversion of the blastoderm occurs, giving rise to nodular atrophic embryos, such as are found in human aborted ova. Calcium salts, in certain concentrations, according to Loeb, retard the growth of the blood vessels of the developing embryo, and indirectly affect its general development. All kinds of gross abnormalities—for example, anencephalus, double monsters, etc.—have been produced by experimental teratologists by mechanical trauma applied to developing embryos at different stages of development. There is abundant proof, therefore, that an abnormal physical or biochemical environment can, and does, act in a deleterious manner upon the developing ovum. At the same time, as pointed out by Professor Arthur Robinson in a recent discussion on the causes of sterility and abortion at the Royal Society of Medicine, pathological ova can develop in the absence of any obvious macroscopic or microscopic lesion in the uterus of animals. Spina bifida is the commonest anomaly, and this has occurred independently of any demonstrable pathological lesion in

the case of Robinson's experimental work on the ferret. He concludes, therefore, that inherent abnormal physiological attributes in the gene are responsible for the pathological lesions that are encountered. In the presence of such divergent views, the truth probably lies somewhere between the two, and both factors may on different occasions be concerned in the phenomena which I have discussed.

Abortion in Relation to Nutrition of the Ovum.

From the preceding remarks it is evident that impairment of nutrition, resulting from faulty implantation, abnormal decidual development, absence of essential food factors, or the existence of lethal toxins, is a potent factor in the etiology of early abortion.

The maintenance of an adequate source of food materials is not affected by the same mechanism in all members of the mammalian family. In certain ungulates and a few rodents the secretion of the uterine glands is the main source from which the developing embryo derives its nourishment. This secretion, known as "uterine milk," is an albuminous fluid containing cast-off cellular elements, but very little is known beyond this. Its exact chemical composition has, I believe, hitherto not been ascertained. In the human subject the zygote is dependent upon absorption from the maternal blood, except for a short period of its existence when the syncytium is actively burrowing and embedding itself in the decidua. At this stage even in the human ovum some of the uterine glands are opened up by the trophoblast, and blood is effused into their lumina *pari passu* with the destruction and solution of the decidual stroma cells. The secretion of the uterine glands is normally rich in calcium and iodine, as shown by chemical analysis of the menstrual discharge; and in the developed decidua, both of menstruation and of pregnancy, there is a marked retention of secretion in the large dilated glands of the stratum spongiosum. I cannot think that this active retention of secretion is of negative value, or is purely atavistic. It may be that there is some diffusion of secretion between the glands and stroma cells of the decidua. Anatomy and comparative embryology have demonstrated the minute structure of the ovum and process of embedding, but there is still much to learn with regard to the physiology of that remarkable organ, the decidua.

Among stock-raisers and veterinary surgeons much importance is attached to-day to matters of feeding and the influence of various food factors upon sterility, and the number and weight of the progeny. At a recent discussion on abortion at the Royal Society of Medicine I drew attention to this matter, particularly with relation to the value of iodine. Experiments at the Staffordshire Farm Institute have shown that sows receiving iodine farrowed 50 per cent. more young than sows that had no iodine. At the Royal Experimental Station, Budapest, when iodine was given to pregnant sows, the average weight of the farrows at weaning was nearly 50 per cent. over that of the group that received no iodine. In the case of birds, the Rowett Institute and West of Scotland Agricultural College found that the egg yield in pullets which received iodine went up 50 per cent. in one year over a pen that had no iodine in the diet. The aggregate egg production where iodine was given in the form of potassium iodide was nearly double that of a pen where iodine was withheld. There is no doubt, therefore, of the value of this element to the pregnant animal, and I cannot help thinking that the iodine content of the uterine secretion in the human female has a similar significance. We know that certain inorganic toxic agents—for example, lead—are transmitted to the ovum, and that they act deleteriously upon the development and function of the syncytium. It is quite possible, therefore, that other agents, especially calcium and iodine, are similarly transmitted, and that they act in a beneficial manner.

During the last few years a considerable amount of work has been done in connexion with the essential food factors known as vitamins, and in 1922 Evans and Scott published the first of a series of papers upon the "existence of a hitherto unknown dietary factor essential for reproduction." This substance, known as the anti-sterility vitamin fat-soluble "E," has been extensively investigated by Evans and his co-workers, and the results of the research are published in an elaborate monograph. Evans worked exclusively with rats, and found that, although fertilization and implantation of the ovum occurs in the absence of vitamin E, the embryos begin to die about the eighth day of gestation, and are later absorbed. They show general under-development, especially in the mesoblastic tissues, entodermal villi, blood islands, and allantois.

The data given in Evans and Burr's monograph provides very interesting reading, and if their results are confirmed a new and fertile field of investigation is opened up into the causes of some obscure early abortions in the human subject. One important fact which emerges from the work is that if vitamin E is withheld from the diet of an animal the initial available stock of this factor is gradually exhausted, both for the general bodily economy and also by any intercurrent pregnancies. Such an animal, although fertile at first, will later abort owing to an "E" deficiency. Subsequently it can be cured of what may be termed the "sterility disease" by the substitution of an "E" for an "E"-free ration.

The distribution of vitamin E in nature is chiefly concentrated in certain seeds and leaves, especially wheat-germ, lettuces, peas, alfalfa, bryophyllum, and begonia. To a less extent it is found in the yolk of eggs, but traces only are present in animal muscle. The vitamin is apparently not destroyed by drying and desiccation at a temperature of 100° C., an important practical point in the preparation of vegetable products—for example, lettuce and wheat-germ—for therapeutic purposes. The value of wheat is due exclusively to the storing of vitamin E in the germ, as white flour is powerless to produce a cure in animals rendered sterile by feeding on "E"-free rations. Chemically the vitamin has not hitherto been actually isolated, although fractional distillation has produced an active body similar in constitution and physical properties to vitamin A and cholesterol. A remarkable resemblance in certain chemical reactions exists between this anti-sterility vitamin and one of the ovarian hormones. As Evans points out, "the partial destruction during vacuum distillation at 200° C., the total destruction by acetyl chloride and bromine, the stability to hydrogenation in the presence of platinum black, the molecular weight, and the elementary analysis all show a general similarity of the ovarian hormone to vitamin E."

This brings me back to the all-important relationship which exists between the ovary and the developing ovum. I have already explained the influence the lutein hormone exerts over the growth of the decidua. Does the similarity in composition and chemical properties between the hormone and vitamin E imply a similar physiological influence over the developing embryo? In other words, does the ovary not only provide the ovum, but also the essential growth factor upon which the future development of the embryo depends? This conception of an essential "growth factor" being present in the ovarian hormone provides an interesting field for thought and investigation, not only in relation to abortion, but also in connexion with certain neoplasms. It appears possible, indeed, that the presence of an ovarian "growth hormone" may account for the rapidity of growth and size of some ovarian tumours, both benign and malignant.

The work of Evans upon "vitamin E" of course needs confirmation by other investigators in other laboratories. Also, it has still to be shown by clinical observation whether the conclusions based upon experiments on rats are applicable to the human species.

During the past few years opportunities have naturally occurred of testing what may be termed the "new sexual physiology" in its application to the treatment of recurrent abortion in the human subject. It is impossible, of course, in isolated instances to know whether a given result is *post* and not *propter* treatment, but the following two cases certainly appeared to have benefited from the exhibition of ante-natal therapy on the lines discussed.

Case 1.—Mrs. L., aged 40, married for three years. Her first pregnancy terminated at the seventh month with the stillbirth of twins. The next gestation aborted at the twelfth week. The third pregnancy again ended with the birth of a macerated foetus at about the twenty-eighth week. The Wassermann reaction

in the case of both husband and wife was negative, and no obvious cause could be found to account for the obstetric clinical history. In March, 1926, the patient again became pregnant, and she was immediately placed upon a diet rich in vitamin E, together with calcium lactate (60 grains per diem) and a preparation of ovarian hormone. The pregnancy progressed to term in a normal manner, and a child weighing 10¼ lb. was delivered by Caesarean section on December 22nd, 1927.

Case 3.—Mrs. S., aged 32, a 2-para. Her first child was premature, and weighed 6½ lb. It was reared with difficulty. The second pregnancy was complicated by hydramnios, and a child showing an extreme degree of spina bifida was born at the thirty-second week of gestation. The patient became pregnant again at the end of November, 1928. She was placed upon a similar regime, with the addition of iodine, and a healthy child weighing 8 lb. was born in September, 1929. The existence of a small elongated dimple over the lower part of the lumbar spine and sacrum showed the tendency to spina bifida which had complicated the preceding gestation.

Contagious Abortion.

I will conclude with a short reference to the question of contagious abortion in relation to the human species. In veterinary medicine infection of the uterus with Bang's bacillus is well known, and it is a frequent cause of abortion among certain infected herds. The Ministry of Agriculture has issued several leaflets upon the subject, and the importance of the infection is emphasized among all farmers and stock-raisers. Recently attention has been drawn to the possibility of transmission of Bang's bacillus to the human pregnant female, and a few undoubted cases of this infection have occurred both in this country and in Denmark.

As a cause of abortion in the human species, however, infection of this nature is sporadic and rare. I have only met with one undoubted example, and this occurred some years ago in the wife of a farmer who had infected stock upon his land. The case was at first regarded as an ordinary infected abortion, but the continuance of pyrexia and the persistence of a grey muco-purulent discharge led to a bacteriological investigation of the uterine cavity. An unusual bacillus in pure culture was found in the discharge, and this coincided in appearance and cultural characteristics with a control tube of Bang's bacillus, supplied by Messrs. Evans and Co. of Liverpool. Following this case a bacteriological investigation was instituted in other cases of infected abortions. Altogether 50 cases were examined, but no other example of infection with Bang's bacillus was found.

The infection is undoubtedly rare, but the possibility of the disease should be remembered, especially in the case of what appear to be septic abortions in rural areas.

The figures accompanying this paper were obtained for me by Miss King, the sister in charge of my department, and by Mr. Jeafferson, my registrar, to whom I take this opportunity of acknowledging my indebtedness.

MASTOID DISEASE WITHOUT OTORRHOEA.

BY

E. WATSON-WILLIAMS, *M.C.*, CH.M., F.R.C.S.ED.,

SURGEON IN CHARGE OF THE EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY.

ACUTE suppurative middle-ear disease is sometimes classified as "mild" in which resolution occurs without perforation of the drum, or "severe" with perforation and aural discharge. With both forms there is no doubt mastoiditis in some degree—suppuration in the antrum and air cells, and associated reaction in the surrounding bone. But only a small proportion of cases go on to what is clinically recognized as "mastoid disease"; in the majority, and almost invariably in the "mild" type, resolution occurs.

Yet if we adopt this classification it is important to bear in mind that definite and even extensive mastoid disease can on occasion occur where there is not, and has never been, any aural discharge. On examining the records of some 300 mastoid operations performed personally since the beginning of 1925, I find fifteen such cases occurring in fourteen patients.[1] Such a ratio is probably much above the normal, as two recent groups of cases are included in this period. With the possible exception of No. 12, these cases, notes of which are subjoined, may be regarded as primary acute otitis—that is, neither recurrent nor chronic. In each case the occurrence of any previous ear trouble, and especially any discharge, recent or remote, has been the subject of particular inquiry.

Preceding Illness.—Influenza had preceded the ear trouble in both the adults (9, 14) and that or a "cold" in three more cases (8, 10, 13). Scarlet fever had been the precursor in one (1). But no fewer than eight of the fourteen patients had been in apparently perfect health immediately before the onset of otitis (2, 3, 4, 5, 6, 7, 11, 12). No. 12 was a congenital syphilitic, but there had been for years no evidence of the disease. Probably in Case 6 the otitis was a sequel of the incomplete adenoid operation.

Pain was present in every case at some point, but in several it was intermittent (11R, 11L, 14), or insufficient for some days to cause the patient to seek advice (2, 3, 4, 10).

Tenderness over the mastoid antrum or process is, except pain, probably the most constant sign of mastoiditis. But in five cases it was quite inconspicuous (1, 5, 8, 11R, 11L), and was absent in two (4, 14 early).

Fever was absent in one case throughout, and in both the adults at the beginning. Only four of the patients had a temperature above 100° F. when first seen.

The tympanic membrane was examined in every case by means of an illuminated magnifying speculum. It was noted as being quite normal in appearance in eight of the fifteen ears (1, 2, 3, 5, 10, 11L, 12, 13).

Post-aural Oedema.—A word in passing as to this symptom. It is in so many cases the outward and visible sign of mastoiditis, and is so invariably illustrated as such in textbooks, that there appears to be some risk lest it should be regarded as a diagnostic criterion, without which we can exclude this complication.[1] It was, in fact, the occurrence of swelling that in ten of these fifteen cases decided me to operate on the mastoid forthwith. Nevertheless, it is well to emphasize that even in acute primary otitis, disease of the mastoid, perhaps quite extensive, may occur where post-aural swelling is inconspicuous (7), or entirely absent (4, 8, 9, 11R, 11L, 14 early).

Pathology.

The ages of the patients in years were 1, 2, 3, 5, 6, 7, 8, 8, 10, 11, 13, 16, 26, 34. These ages are what one would expect in a group of primary acute otitis. A striking feature of the records (which are usually very brief) is the frequency with which mention is made of the cellular nature of the bone. This conspicuous development of the cells may be an etiological factor—that is, it was because the bone was unusually cellular that mastoid swelling appeared early and before perforation. But since this feature was specially noted in four of the five cases where no oedema had occurred, that cannot be the only explanation.

In four cases a perisinus abscess was discovered at operation (4, 7, 8, 14), and in two of these the sinus contained old clot breaking down (4, 8). It is to be noted that in both these cases the drum had appeared normal when first examined, mastoid oedema was absent, and tenderness absent in one and quite slight in the other.

The pus was examined in eight cases, in two of which no growth of organisms was obtained. During 1929 special attention was directed to the possibility of a *Streptococcus mucosus* infection. Both then and before the report was uniformly "streptococcus," that particular type not being found. Furthermore, the clinical course was not that

characteristic of a *Streptococcus mucosus* infection. A curious feature is the tendency of the cases here recorded to occur in little groups, thus:

1925. June 23rd, 24th.*
1928. March 2nd,* 18th,* 19th,* 28th.
1929. March 1st, 2nd.
May 18th,* 23rd,* 25rd, 25th.

* Signifies that there had been no preceding illness.

This may be mere coincidence, but it does at least suggest that at certain periods or during certain epidemics there may have been a specially (perhaps attenuated) "mastoidotropic" virus in circulation.

We have, then, a group of cases in which

(1) There is often no preceding illness;
(2) There neither is on examination nor has ever been *any otorrhoea*;
(3) Pain may be slight or have ceased;
(4) There may be little or no tenderness;
(5) Fever may be mild or absent;
(6) No oedema may be discoverable;
(7) The tympanic membrane may appear quite normal;

and yet *all the time there is serious mischief in the mastoid* requiring operation.

For example, Case 4. When I first saw this little "pink and white" girl she seemed well in herself; constipation might account for the overnight feverishness and some "fractiousness." The pain was not more than a tight bump of wax could produce. On removing the wax the drum looked quite normal (and even next day the pinkiness was not more than what often follows removal of cerumen). There was not the least trace of oedema, or tenderness on pressing or percussing the mastoid or pulling the ear. Within twenty-four hours she had a rigor.

In Case 8 the clinical picture was at first that of simple otitis media. Myringotomy was followed by a free discharge, and relieved pain and tenderness. The temperature did not fall as "cleanly" as one expected, but by the fifth day it was down to 99°. The boy looked and said he felt perfectly well, even later, when the temperature went up, he was sleeping soundly, and his appetite in an adult would have been called voracious. There was no pain in the ear, and only the slightest returning tenderness. Yet the clot in the lateral sinus was beginning to break up.

In Case 14 there had been no pain, tenderness, or oedema. The right ear was not even deaf, though it had been. The drum was grey and retracted; there was nothing to suggest fever or any sign of toxaemia. But it seems hardly credible that the extensive destruction of bone, found three days later to have exposed the sinus in a pool of pus, had not already made considerable progress.

The treatment in all the cases was a Schwartze mastoid operation. Eradication of cells was as complete as possible, and in most cases the whole mastoid process was removed. The lateral sinus was exposed in all cases, a point that I believe to be of great importance. Except in the three older patients and where specially mentioned, adenoids were removed at the time of the mastoid operation. The eventual result has been uniformly good, and all the patients have normal hearing.

BRIEF NOTES OF CASES.

Case 1.

A. C., aged 7, had had a tonsil and adenoid operation in 1924. On June 23rd, 1925, he complained of pain in the right ear, localized at the tragus, for one day, following scarlet fever. There was definite mastoid oedema and slight tenderness; the tympanic membrane was normal; temperature 99.4°. A Schwartze mastoid operation was performed, revealing pus throughout the mastoid process. Convalescence was normal.

Case 2.

R. A., aged 16, came on June 24th, 1925, complaining of pain behind the right ear for one week, and a tender swelling for one day. There had been no preceding illness; never aural discharge or previous ear trouble; the tympanic membrane appeared normal. Temperature 101.2°. A Schwartze mastoid operation showed great destruction of bone in a mastoid of cellular type; very little pus. Complete recovery.

Case 3.

E. F., aged 3, came on February 14th, 1926, complaining of a tender swelling behind the right ear for one day. There had been earache for one week, but no discharge or previous trouble with the ears; no recent illness. The tympanic membrane was normal; no fever. A Schwartze mastoid operation showed that the antrum contained pus. Convalescence was normal.

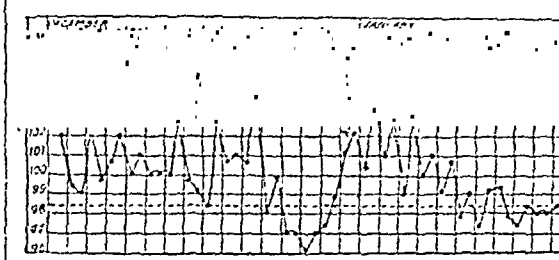
Case 4.

I. W., aged 8. Seen on December 17th, 1927, complaining of pain in the right ear for three weeks; there had been no discharge; no preceding illness. Tonsil and adenoid operation in 1921. She was feverish the previous night; temperature when seen was 99°. She had facial impetigo, and was very constipated. No post-aural tenderness, pain, or oedema. The tympanic membrane, after removing a plug of wax, was quite normal.

At 6 a.m. on December 18th she had a rigor (101°, see chart). That morning she again complained of pain in the right ear, not severe; there was still no trace of mastoid tenderness or oedema, but the tympanic membrane was pink, not bulging.

Immediate operation. Myringotomy produced a single bead of pus, much blood. A Schwartze mastoid operation was performed; the bone was normal, but the antrum contained pus; the lateral sinus and its groove appeared healthy.

Next day her midday temperature was 95°, and she seemed well. On December 20th (*third day*) she had a slight rigor, with



return of fever, but seemed well; no pain. The day after that the fever had disappeared, and she seemed very comfortable that day and the two following (21st to 23rd), though the temperature rose on the evening of the 22nd. A skiagraphic examination was made of the chest, and reported "early miliary tubercle of right lung." The mother then said that she had been getting "shiverings" for three weeks. At 10 p.m. on December 23rd a third rigor occurred. I tied off the jugular vein, and exposed the sinus. Two part that had been exposed before seemed quite normal, but the bulb lay in an old stinking abscess, and was full of clot breaking down.

Four days after this operation the temperature came down, and although the neck wound suppurated later, and there was subsequently a perichondritis of the opposite ear, convalescence was otherwise uneventful. I was led to seek suppuration in the bulb by the similarity of this case to one I had had previously; in that, although there was bilateral otorrhoea, the complete absence of mastoid tenderness and oedema, and almost complete absence of pain, caused a delay of several days before the thrombosed jugular bulb was exposed.

Case 5.

P. T., aged 11, on March 2nd, 1928, complained of pain in the left ear and swelling behind it for four days; no preceding illness; never any ear discharge. The tympanic membrane appeared normal. Temperature 100°. Immediate Schwartze mastoid operation. A periosteal abscess was found; the bone was engorged, but did not contain macroscopic pus. No adenoids were present. Convalescence was normal.

Case 6.

W. A., aged 5, had had a tonsil and adenoid operation (elsewhere) a month previously. On March 19th, 1928, he came complaining of pain in the left ear for five days. Before that he had been quite well; the attack started with vomiting for one day, and there had been epistaxis and vertigo two days before he came up. Never any aural discharge. A tender swelling was present rather below than behind the left ear; there was no deafness, but the membrana flaccida was bulging. Temperature 102°. A Schwartze mastoid operation showed extensive damage to the bone in an exceptionally cellular process; the lateral sinus was healthy. A strip of adenoids was removed from the left lateral recess of the pharynx. Convalescence was normal.

Case 7.

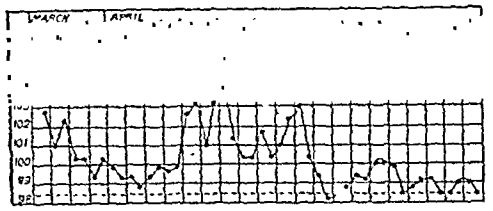
W. W., aged 10, on March 18th, 1928, complained of pain and a swelling behind the right ear; it had been present for two days. Patient had had no aural discharge, but a little earache three weeks previously, quite inconspicuous. On examination there was found a slight post-aural oedema, tender; oedema of postero-superior meatal wall hid the tympanic membrane, but there was no discharge. Temperature 99.8°. Immediate Schwartze mastoid operation. Very cellular process, with considerable destruction of bone. The lateral sinus came unusually far forward, and lay in a large abscess; it was red but not thrombosed. Convalescence was normal.

Case 8.

P. C., aged 13, came on March 28th, 1928, complaining of pain in the left ear for four days following a cold, and deafness. Had never had any previous ear trouble. There was slight tenderness of the mastoid process, but no trace of swelling. The tympanic

membrane was pink and bulging. Temperature 102°. Myringotomy produced blood only. Next day the ear was discharging pus freely, but there was still some tenderness.

By the seventh day he was feeling quite well, and free from pain, though the ear was still discharging, and the temperature was not quite down to 98° (see chart). That evening his temperature rose, and was 104° at noon on April 5th. At this point



it remained for three days. The boy was sleeping and eating well; there was *no vomiting, no rigor; the only* pain was a slight frontal headache; there was *no trace of* mastoid oedema, *but on firm pressure* the process was *just* tender.

A Schwartze mastoid operation showed a cellular bone much engorged, but free from pus except in one or two cells deep below the antrum, and a little purulent fluid in the apical cells. On opening the sinus groove a large offensive abscess was exposed, with the sinus lying in it thrombosed, perforated, and the thrombus beginning to break up. The jugular vein was not tied. Convalescence was normal.

Case 9.

S. B., aged 34, on March 1st, 1929, came complaining of pain in the left ear for one week following influenza. There was no trace of mastoid oedema, but definite tenderness; the tympanic membrane was bulging and a dusky pink. Temperature 98.4°. Myringotomy produced blood only, no pus. During the following days the aural discharge was purulent; definite mastoid tenderness persisted, but without any swelling; there was slight fever. Pain and fever tending to increase, a Schwartze mastoid operation was performed; the bone was very cellular; the cells contained a serous fluid and two small beads of pus only. Complete recovery.

Case 10.

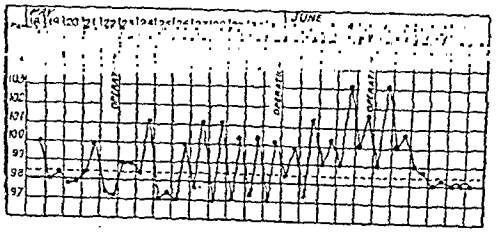
G. R., aged 2, came on March 2nd, 1929, complaining of a swelling above the right ear for one day, but behind that ear for four days. Influenza fourteen days before, but never any aural discharge. Temperature 99.2°. The swelling was tender, but the tympanic membrane appeared absolutely normal. Immediate Schwartze operation revealed a large subperiosteal abscess, chiefly above the ear, and a mastoid process full of thick granulations, all bony trabeculae having disappeared; the lateral sinus was normal; large adenoids were present. Convalescence was uneventful.

Case 11.

J. R aged 8, came on May 18th, 1929, complaining of intermittent earache on alternate sides during the last week; now absent. Never any aural discharge. The pain came on of itself, when he was quite well. Temperature 100°. Small flat tonsils; large adenoids; nose normal. The left tympanic membrane appeared quite normal, the right was depressed.

The complaint of earache on one side or the other persisted, but no further evidence appeared; there was no trace of mastoid swelling, but slight and variable tenderness over the mastoid antra; this had possibly been present before he came, as he was sent to me as a case of mastoid disease. On May 22nd I removed tonsils and adenoids, and opened both maxillary antra, which were full of thick muco-pus, later reported streptococcal.

The temperature had never quite settled (see chart), and on the fifth day after operation (May 27th) went to 101.2° in the evening. For the next five days it swung up to this point every evening, and was down every morning. The boy seemed very well; the hearing was normal; there was the same variable, transient,



and quite slight earache and tenderness over the mastoids. On May 31st he was slightly deaf, and complained of bubbling in the ears. There was no oedema, but slight tenderness on the right mastoid; the membrana flaccida of that side appeared red, but the whole drum was retracted. Earache was present only on the left side, where the drum and mastoid seemed normal. I diagnosed a very quiescent mastoiditis, but thought it well to try a paracentesis. On the right side this produced blood, which on culture grew streptococci; on the left there was definite pus, from which *Staphylococcus albus* grew. The next day the temperature tended to be lower, and for three days there was no pain. By June 5th, however, the earache had recurred, though it was not severe; there was profuse aural discharge; the evening temperature was 103.2°, and both mastoid processes were slightly tender on firm pressure.

The Schwartze mastoid operation was therefore performed on both sides, with identical findings—a bone cellular, congested, infiltrated with muco-pus; the sinus normal. Convalescence was marked by a bout of fever and thirst—possibly iodoform poisoning—but was otherwise normal; the nose and both ears are now quite dry, and hearing normal. The mastoid infections were streptococcal on both sides. I have no doubt that there was definite mastoid disease at least as early as the day of the paracentesis.

Case 12.

M. B., aged 6, a congenital syphilitic, had had occasional earache, but never discharge; tonsil and adenoid operation in 1927. On May 23rd, 1929, she came complaining of pain in the left ear for four days without preceding illness, and a recent tender post-aural swelling. The tympanic membrane was normal; temperature 99°.

An immediate Schwartze operation showed the mastoid bone congested, but without actual pus. Large adenoids were removed. Two days later she was crying with earache, and a paracentesis was done. A third attack of pain occurred on the tenth day, with a rise of temperature to 103.4°, but this cleared up the next day. On that day haematuria was observed. It is curious that the same sequential haematuria had occurred after the tonsil operation, and in both cases it was suggested that scarlet fever had been "missed." Convalescence was uneventful.

Case 13.

S. N., aged 1, came, on May 25th, 1929, complaining of two days' pain in the left ear, following a cold, and recent post-aural swelling. The swelling was tender and red, but there had never been any aural discharge, and the drum appeared normal. Temperature 102°. An immediate Schwartze mastoid operation showed the whole mastoid and adjacent bone to be congested, dripping blood, but no pus was found. Large adenoids were removed. Convalescence was normal.

Case 14.

C. F., aged 26, came, on May 23rd, 1929, complaining of tinnitus in both ears for two weeks following influenza, without pain. Never any aural discharge or previous ear trouble. At first both ears had been deaf, later only the left. The right tympanic membrane was grey, the left pink, and both indrawn. On inflation air entered both ears with a distinct labial sound, relieving deafness and tinnitus. Three days later he returned with a tender swelling extending from the level of the right mastoid antrum for four inches down the neck, and earache. The drum was neither swollen nor red, but yellow pus could be seen through it. Temperature 101.2°.

A Schwartze mastoid operation showed a typical von Bezold abscess beneath the sterno-mastoid muscle, communicating with the mastoid through a hole in the anterior part of the process; through the latter pus pulsed out. The cortex was somewhat thick, but proved to be a mere shell enclosing a large cavity in which lay the lateral sinus, apparently healthy. Convalescence was normal. The absence of all pain on the first visit caused me to make a diagnosis of catarrhal otitis. I do not believe it possible that in examining the ear either tenderness or oedema was overlooked, but the operation showed that extensive disease of the mastoid must have been already present.

TWO CASES OF PARAFFINOMA.*

BY

A. T. BAZIN, D.S.O., M.D., C.M.,

PROFESSOR OF SURGERY, MCGILL UNIVERSITY, MONTREAL.

THIS communication consists of a report of two cases of tumour formation resulting from injection of paraffin or paraffin oil. In both instances the tumours consisted of hyperplasia of connective tissue of dense cicatrizing character, the bulk being further added to by the contained paraffin.

Clinical observation and experimental work with monkeys have demonstrated that mineral oils, when injected into the tissues, may cause foreign body reaction with formation of tumour masses. It is apparent that some individuals are susceptible, and the reaction may be severe, with very extensive mass formation. In other individuals there is no tissue reaction. In some instances the injected paraffin oil has been observed to spread along the lymph channels and

* A paper read in the Section of Surgery at the Annual Meeting of the British Medical Association, Manchester, 1929.

the lymph nodes, there producing a condition simulating tuberculous adenitis or malignant lymph metastases. Vegetable oils (olive and cotton-seed) do not, experimentally, produce these tissue masses.

CASE I.—*Paraffinoma of the Rectum.*

A married woman, aged 52, was admitted to my private service on July 2nd, 1928, complaining of an increasing difficulty in obtaining evacuation of the bowels, with periods of two to three days' duration of impaction with absolute obstruction. She was referred by two physicians, who in consultation had diagnosed carcinoma of the rectum.

The past history relevant to the existing condition was as follows. In 1920 I had operated for acute cholecystitis; at that time she suffered from prolapsing internal haemorrhoids of sixteen years' duration, radical treatment of which was postponed to a more convenient season. In March, 1927, being in California, she received eight office treatments at weekly intervals. These treatments for the haemorrhoids were under local anaesthesia. She asked but received no information regarding details, but an attendant accompanying her stated that the surgeon appeared to use an apparatus wrapped in a towel from which protruded a nozzle. These treatments promptly caused disappearance of the prolapsing haemorrhoids.

In April, 1928, she returned and had one treatment for a pile which had not completely disappeared. Shortly after this last treatment she noticed an increasing difficulty in satisfactorily emptying the bowel, and from time to time was forced to use oil enemata to gain comfort. Late in June, 1928, an impaction occurred which was unusually resistant to treatment, was associated with distension and vomiting, and was finally relieved by oil followed by soapsuds enemata. She then sought advice.

Digital Examination.—There was first noted an absence of the prolapsing haemorrhoids present in 1920. One and a half inches from the anal orifice the finger encountered a nodular mass, completely encircling the bowel and causing stenosis, which would admit the tip of the finger only. Under anaesthesia the stenosis was dilated and the finger passed through. In vertical diameter the infiltration occupied 2¼ inches; the mucosa was smooth, mobile, and nowhere presented ulceration. Extending distally from the constricting ring there were tongue-like processes beneath the mucous membrane.

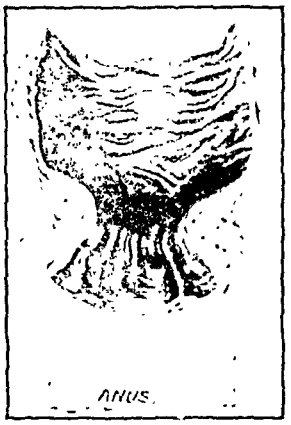

FIG. 1.—Photograph of drawing of gross specimen. Note (1) the constriction produced by dense connective tissue, infiltrated and distended by globules of paraffin; (2) absence of ulceration; (3) finger-like processes extending distally from the area of constriction; (4) distance from anal orifice; (5) proximal to the constricting ring there is dilatation of the lumen, also hypertrophy of the muscle layers.

The appearance simulated carcinoma, but had marked points of difference. A stenosing scirrhous cancer is extremely rare in the ampulla and is not associated with submucous infiltration in long processes with an overlying mobile mucosa. The absence of ulceration eliminated other varieties of carcinoma of the rectum, except the type known as Krukenberg's tumour. A blood Wassermann test proved negative.

A section was removed for biopsy, choosing one of the outlying processes, and removing it entire with the overlying mucosa. The pathologist's report was inconclusive. Vacuoles were discovered and giant cells, but the pathologist could not be convinced but that he was reporting upon the extremity only of a papilloma and that the section had not passed through the base.

In the meantime the history detailed above had been elicited, and I inferred that the apparatus used by the surgeon was wrapped in a towel because it was hot. The conclusion arrived at was that hard paraffin, melted, had been used as injection to fix the prolapsed haemorrhoids. The diagnosis of paraffinoma was made.

The question of treatment then arose: (1) A disabling stricture was present. (2) The pathologist and consultants were not convinced that in some portion of the mass there might not be a malignant change. (3) A paraffinoma has potential possibilities of developing into carcinoma.

It was decided to do a resection, preserving the lower end of the canal with the sphincters and restoring continuity by rectorrhaphy. This procedure was carried out on July 12th through a modified Kraske incision. The results have been completely satisfactory. Examination one year later demonstrates an active sphincter control, a smooth mucosal surface, and no areas of submucosal infiltration.

CASE II.—*Paraffinoma of Thigh.*

The patient in this case was a woman who, eight years previously, had received three injections of camphor in oil as a cardiac stimulant during a severe illness. At the site of each injection there has gradually and progressively developed a nodule, the removal of the largest of which furnished the section shown in Fig. 4. It has been determined that the camphor was dissolved in a paraffin oil base.

The important deduction from a study of these two cases is the danger of using mineral oil for injection, either as a vehicle for drugs or otherwise.

Notes on paraffinoma appear occasionally in the medical press, in which various opinions are recorded. B. F. Davis,[1] in 1920, reported a case in which apparently solid paraffin was used and not paraffin oil. Oppenheimer,[2] in 1920, stated that the use of paraffin subcutaneously had decided risk. Morts[3] says that paraffin injection is not dangerous if pure grade oil, with melting point of 110° to 115° F., is used. Weidman and Jeffries,[4] writing in 1923, showed that plain paraffin oil and camphor in paraffin oil were both effective. The oil may remain for eleven months before tumours appear. Monkeys were used in their experiments.

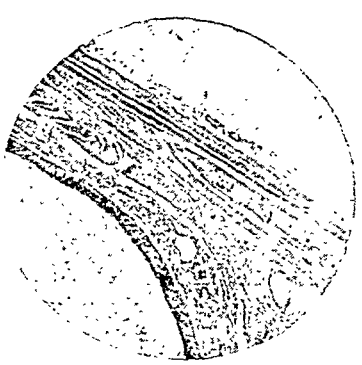

FIG. 2.—Section through margin of tumour. Note (1) the intact mucous membrane; (2) the distortion and fragmentation of the internal muscular coat; (3) the abrupt margin of involvement; (4) the large number of vacuoles, most numerous in the submucosa.

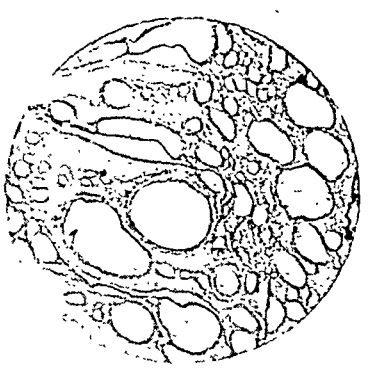

FIG. 3.—Section through submucosa showing amount of contained paraffin as represented by the vacuoles. The connective tissue reaction is well seen in formation of concentric rings about the paraffin mass.

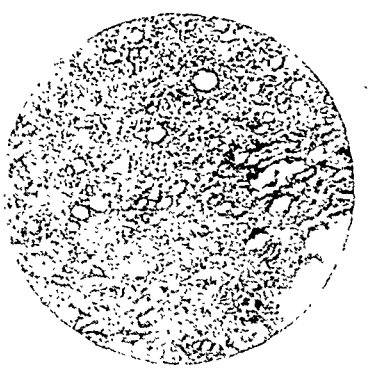

FIG. 4.—Section of a mass removed from the subcutaneous tissue of a woman with paraffinoma of thigh (see Case ii). Note the vacuoles from which paraffin has been dissolved in the process of fixation, also the dense connective tissue. There is also marked lymphocytic infiltration, particularly in spots.

ARTERIO-SCLEROSIS IN COAL MINERS.

BY

D. ELLIOT DICKSON, M.D., F.R.C.S.Ed.,
LOCHGELLY, FIFE;
AND
W. ARNOTT DICKSON, M.D., M.R.C.P.Ed.,
F.R.C.S.Ed., D.P.H.,
GLOUCESTER.

ALTHOUGH it is now generally held that the conditions connected with a miner's occupation, apart from its special risks, are as favourable to health as those of other manual workers, it should be noted that after the age of 55 coal miners in the aggregate die off more rapidly than other occupied males, while between the ages of 25 and 55 the death rate is lower.

TABLE I.—*Occupational Mortality at Different Age Groups.*
(From the Registrar-General's Returns, 1921-23, p. 8.)

Age Groups:	25-	35-	45-	55-	65 and up.
Occupied males	100	100	100	100	100
Miners	91	88	84	105	130

The Registrar-General's return for 1921-23 says: "Analysis of the causes throws very little light on the reason for the relative increase which occurs in the mortality of miners."

Twenty years ago, while associated in a large practice in Fife, we noted with surprise many cases of arterial thickening among coal miners, even in quite young men. This discovery suggested the systematic examination of a considerable number of miners. In all, 500 men were examined. They were taken consecutively, as they came into our surgeries, but no one was included who complained of any symptoms referable to his circulatory system. As a matter of fact, many of them were literally taken in off the street for the purpose of this inquiry.

Even at this late date it seems desirable to publish the results, as no work on similar lines has been undertaken in the interval, and no light has yet been supplied to the Registrar-General. It is possible that our results contribute one explanation of the anomaly to which he refers.

Scheme of Examinations.

The examinations were carried out, as a rule, in the evening between 6 and 7 o'clock; a few were done in the morning between 9 and 10. All the men had been off work for at least four hours, and no man was examined immediately after a meal. The routine procedure was as follows. While the man was standing his pulse rate was counted and the condition of the wall of the radial artery was noted. He was then directed to lie down, when particulars of his habits as to alcohol and tobacco, and the conditions of his work, were obtained, and his medical history was inquired into. The chest wall was then exposed and the apex beat located, the cardiac dullness mapped out, and the different areas auscultated. The pulse was again counted. The patient was then seated on a chair, the left arm bared to the shoulder, and the blood pressure taken (a mercurial manometer and a 12 *cm.* armlet were used throughout). In a limited number of cases a blood count was done and a haemoglobin estimation made. The majority of the men examined were of the phlegmatic type, so that little effort was required to secure the psychical repose which is so desirable in taking blood pressure readings.

Results.

It may at once be stated that the outstanding feature of this inquiry has been the discovery of an extraordinary prevalence among miners of arterial thickening, as evidenced in the radial artery, a prevalence hitherto undescribed, and apparently unsuspected. Of the 500 miners examined only 44 (9 per cent.) had arteries which could not be palpated. The remaining 456 (91 per cent.) had definitely palpable arteries.

There is, of course, no difficulty in determining when an artery is thickened. It is as easy to feel a thickened artery as it is to feel a rubber tube; the difficulty arises when one tries to convey an idea of the amount of thickening present. For purposes of tabulation an attempt has been made to classify these arteries under the following definitions.

A. *Not Palpable.*—An artery the wall of which cannot be detected by the pulp of the examining finger.

B. *Thick.*—An artery whose wall can be flattened by the finger, but can then be easily felt in its entire breadth, like a piece of thick tape.

C. *Very Thick.*—An artery whose wall rolls readily under the finger, like a piece of rubber tubing, and can be flattened only with difficulty. It is nearly always tortuous.

D. *Atheromatous.*—This is the "ipecacuanha root" artery of the late Dr. G. A. Gibson, showing marked calcareous degeneration.

No attempt was made to measure the actual size of the arteries, and the description applies solely to thickness, as gauged by palpation.

The total number of arteries classified under each group is as follows: A, 44; B, 318; C, 136; D, 2. These figures convey an idea of the general type of thickening met with. Since the age factor enters so largely into the question of arterial changes, we have arranged the 500 cases according to age, as shown in Table II.

TABLE II.—*Arteries Arranged in Age Groups; showing Actual Numbers and Percentages.*

Age in Years.	A.		B.		C.		D.		Total No.
	No.	Per cent.	No.	Per cent	No.	Per cent.	No.	Per cent.	
20 and under ...	16	13 8	91	80.9	6	5.1	0	—	116
21-30	17	9.4	128	71.0	35	19.4	0	—	180
31-40	11	10 1	61	54.7.	39	35.0	0	—	111
41 50	0	—	25	41.3	35	58 6	0	—	61
Over 50	0	—	10	31.2	20	62.4	2	6.2	32
Totals ..	44		318		136		2		500

The salient feature of these figures is the very great frequency of arterial thickening in youths of 20 years of age and under. While the proportion of normal (A) arteries in that particular group is greater, as would be expected, than in any other, yet to have so preponderating a proportion of thickened radials (100 out of 116) in healthy boys of 14 to 20 years is exceedingly striking. After the age of 40 none of the men had arteries which were not palpable. With increase of age there is a gradual and almost uninterrupted progression in the thickening of the arteries.

Pathology of Arterial Thickening.

Arterial thickening as evidenced in the radial artery may be due to one of three different conditions: arterio-sclerosis, atheroma, or hypertonus. Arterio-sclerosis may be defined in general terms as a diffuse organic thickening of the arterial wall perceptible to the sense of touch, and extending as far as the artery can be traced. Atheroma is a focal or nodular thickening, due largely to calcareous degeneration. Professor William Russell has introduced the term "hypertonus" to describe a vessel "the muscular coat of which is unduly contracted, so that the wall is thicker and the lumen smaller."

We obtained specimens of several radial arteries from men who met with fatal accidents during the course of our inquiry. Dr. L. R. Sutherland, professor of pathology in University College, Dundee, very kindly examined these for us. Excerpts from his reports are as follows.

Section of Radial from a Man aged 27.—"Localized thickenings of the intima are readily observed: in some sections as much as one-third of the lumen is involved. Some of the patches are six times as thick as the normal intima. The thickened tissue is tolerably cellular. There is no evidence of fatty degeneration or

calcareous infiltration. *The media underlying the larger thickenings is atrophied.*"

Sections from the other arteries show similar changes varying only in degree. Photomicrographs of two sections are reproduced; the first (Fig. 1) shows a patch of thickening of medium size at the giving off of a small branch, and the other (Fig. 2) shows the cellular nature of the thickening.

These reports give a clear indication of the pathological conditions of the arteries in the cases we have examined. The thickening is shown to be in the intima, and does not involve, in any of the sections examined, the whole circumference of the vessel, and there is *no evidence* whatever of thickening of the muscular coat or adventitia.

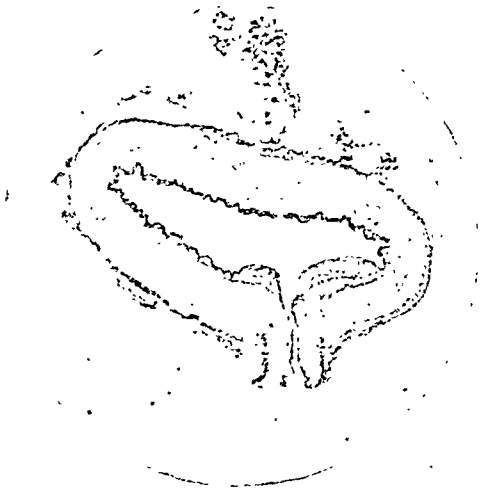

FIG 1.

So far as we can discover, arterial changes similar to *those have never before been described.*

Blood Pressure.

As blood pressure varies within certain not yet accurately defined limits, not only in different individuals, but to almost as great a degree in each individual under the influence of various conditions, there can be no fixed standard of normal blood pressure. But 90 mm. of mercury with the 12 cm. armlet is accepted by most authorities as the lowest systolic pressure in adult males consistent with health; while 140 mm. may be taken as the greatest systolic pressure which should be regarded as normal, at least up to middle life. Of our cases 449 out of the 500—that is, 90 per cent.—had blood pressure falling within normal limits, and only 51 (10 per cent.) showed blood pressure over 140.

The estimation of the diastolic pressure was discontinued after about two hundred readings were taken, as it was apparently of little significance so far as the inquiry was concerned. It was practically always from 25 to 40 mm. below the systolic pressure, as has been found by other observers. The blood pressures at different age groups are shown in Table III.

Relation of Arterio-sclerosis to Blood Pressure.

There exists even now a general impression that arterio-sclerosis is necessarily associated with increased blood pressure. Professor William Russell, for example, asserted that "*thickened arteries never give normal readings.*" The result of this inquiry is entirely opposed to that view. Over and over again we met with cases where the arteries *were very thick and the blood pressure was well below the* normal maximum; while, on the other hand, perfectly soft-

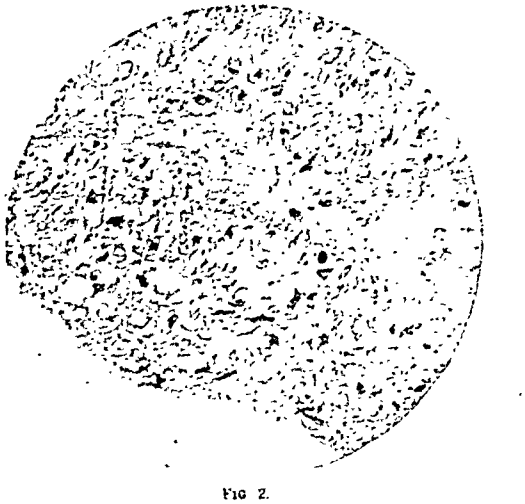

FIG 2.

walled arteries were found in conjunction with high readings. We annex a number of cases showing great variations in blood pressure from arteries of the same apparent degree of thickening.

TABLE IV.

Case.	Age.	Condition of Radial.	Blood Pressure.
G. McL.	15	A	85
T. W.	36	A	110
J. C.	18	B	95
W. B.	32	B	165
C. S.	25	C	110
J. B.	42	C	140

A table is also given of the actual numbers showing "normal" pressure in each artery group.

TABLE V.

Artery Group.	No. of Cases.	Normal Blood Pressure.	Above 140.
Group A	44	42	2
Group B	318	296	22
Group C	136	110	26
Group D	2	1	1

This seems to show that the recorded blood pressure has little relation to actual thickening of the artery wall, within certain limits. (It should be mentioned that in any case where there was unduly high blood pressure the urine was examined for albumin, but with a negative result in every case.) Russell's assertion that "thick-walled" arteries never give normal readings" is disposed of by such a case as the following.

S. S., aged 42, had very thick and tortuous arteries, which could be traced from his wrist right up to his axilla, and felt between the finger and thumb to be round and hard like a lead pencil; his blood pressure was on several occasions 118 to 120. A tracing of this case is given (Fig. 3), showing the first return of pulsation after obliteration of the vessel, and the abscissa, from which one can measure the absolute height of the blood pressure without the risk of error due to the personal equation. This tracing was *kindly made for us by the late Dr. G. A. Gibson, who confirmed* our description of the arteries. The blood pressure was 118.

Many of our cases distinctly showed hypertonus; in fact, as the great majority had normal blood pressure, it is safe to conclude that the others were examples of hypertonic contraction. This was evident during the course of the examinations, when occasionally pressures were recorded

from men who had just had teeth extracted, whitlows opened, and the like, and almost without exception these were over 130.

Clifford Allbutt described three varieties of arterio-sclerosis: (1) hypertonic, with increased blood pressure;

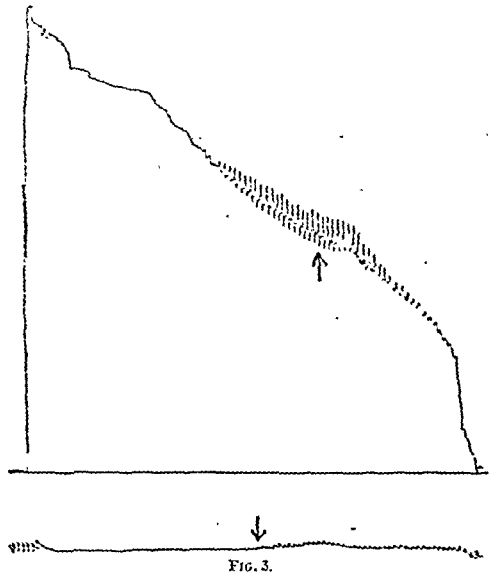

FIG. 3.

(2) toxic, in which there is usually no increase of blood pressure, and not infrequently a decrease; (3) decrescent, or senile. There is no doubt that most of our cases are examples of Clifford Allbutt's toxic group—that is to say, they have thickened arteries, with normal or low blood pressure.

Causes of Arterio-sclerosis.

The subject of the causation of arterio-sclerosis is as darkened by conflicting statements as is the pathology. Kidney disease, old age, high blood pressure, defective alimentation, chronic intoxications of all kinds, acute infections, muscular exertion, have all in turn been brought into the limelight. These seemingly widely divergent views as to the etiology may perhaps be reconciled by considering them all as variations of the one common factor—that is, a toxaemia.

In our cases the following points were investigated: (1) acute infections, including syphilis; (2) meat consumption; (3) amount of tobacco used; (4) alcohol consumption; (5) conditions of work. The first four of these may be dismissed briefly, as they did not suggest any explanation of the prevalence of the thickened arteries. It is perhaps worth recording that only two patients gave a history of syphilis, and these were both ex-soldiers. (This was pre-war.) Syphilis among miners is exceedingly rare.

The results of the inquiry as regards alcohol should also be recorded. The easiest and probably most nearly accurate method of estimating the amount of alcohol consumed by an individual in this walk of life is to ascertain *how much he spends on alcoholic liquors per week.* Our figures are as nearly right as any obtainable, for we know personally practically every man examined, and had a very good idea of his tastes and opportunities.

TABLE VI.—*Effect of Alcohol; showing Condition of Radials and Blood Pressure.*

Amount Spent on Alcohol Per Week.*	No. of Men.	Condition of Radials.				Blood Pressures.

Totals	500	44	318	136	2	20	213	205	62

*N.B.—The values, both monetary and alcoholic, are "pre-war."

This table, contrary to expectation, shows that there is no essential relation between the amount of alcohol taken and the degree of thickening of the arteries or the blood pressure. Similar tables could be given in connexion with meat and tobacco, again showing no relation between these conditions. We therefore came to the definite conclusion that alcohol, meat, and tobacco have little or no effect in causing the changes in the circulatory system which we have described.

The fifth point investigated, "conditions of work," presented the only factor common to all the cases, and special attention was naturally directed to these conditions.

When this inquiry was undertaken there was little coal-cutting machinery below ground; most of the hewing was done by hand, and at that time it was agreed by experts that the actual physical work required of coal miners was *not in* excess of that of any class of ordinary workmen—for example, joiners or bricklayers. Any difference in the mortality rates between miners and other occupied males is certainly not due to any excessive muscular effort required by their work.

In the area under investigation the pits vary in depth from 600 to over 2,000 feet; they are ventilated generally on the vacuum system, by which means a current of air which may amount to 200,000 cubic feet per minute is distributed through the workings. Though this seems a large quantity, it must be remembered that there are over twenty miles of underground roads in a large pit. As the coal is worked out in any area of a pit, the strata left are at first supported by timber pillars, so that these waste workings contain a vast quantity of decomposing wood. The practical importance of this will be noted later.

Since the miner works down the pit for eight hours each day, it is obvious that the composition of the air which he is breathing for such a period is a matter of great importance. We therefore secured analyses of samples of the air from various parts of one of the typical pits in the area. The two abnormal constituents which may be found in mine air are CH_4 and CO. CH_4 (fire-damp as it is called) has no direct action on man, and acts simply as a diluent of the oxygen. CO is only present in exceptional circumstances—for example, when a seam of coal is burning, or after an explosion, either of fire-damp or in the process of coal-getting by explosives. The figures concerning these gases, as well as of the nitrogen present, are therefore left out of the analytical samples given in Table VII.

TABLE VII.—*Analyses of Air in Typical Pit (Percentages).*

Place of Observation.	CO_2.	O_2.
1. At surface	0.03	20.94
2. Pit bottom	0.05	20.85
3. Intake air course 1,000 feet from bottom	0.15	20.59
4. At a working face	0.30	19.84
5. ditto	1.35	19.29
6. ditto; sample taken on pavement ...	4.56	13.13
7. Total return air of pit taken in the up-cast shaft in a current of 200,000 cubic feet per minute	0.22	20.51

We would draw special attention to the amount of CO_2 present in different localities in the pit, and contrast it with the normal and "extraordinarily constant" amount in air above ground—that is, 0.03 per cent.

The figures given do not represent bad ventilation from the mining standpoint. We have it on the authority of several general managers that air containing 0.7 per cent. of CO_2 represents good ventilation, while working places showing 1.35 per cent. and the like are referred to by the miner himself as having "dull air," and it is notorious that men work in such atmospheres for prolonged periods without raising serious objections. In these atmospheres a lamp will burn somewhat dimly, not owing to the actual quantity of CO_2 present, but to the deficiency of oxygen; and a light (a tallow candle) only gradually goes out when the oxygen is reduced to 17.6 per cent. Such atmospheres have little or no appreciable effect on breathing, pulse rate,

or blood pressure. We tested this on ourselves below ground in "dull air," and in one section which had been abandoned on account of bad ventilation. The differences noted were: slight slowing of the respiration (16 as compared with 18 above ground), and slight increase in pulse rate (84 and 72); it was not possible to take a blood pressure reading there as the light was so poor.

The large amount of CO_2 in mine air requires some explanation. There is, of course, no consumption of CO_2 underground; on the contrary, it is being produced constantly. The amount present is only to a very slight degree due to respiration of men and ponies and the burning of oil lamps. It is almost entirely due to the oxidization of wood and of the exposed surfaces of the coal, together with the gas actually liberated from the coal itself.

The other obvious abnormal factor in the conditions of work underground, in addition to the composition of the inspired air, is the absence of daylight. It is evident that in winter, at least, many miners seldom see sunlight or even daylight. The importance of this is only now being fully recognized, but at present we are not prepared to assess its significance in the subject under inquiry. We have, however, been able to trace a progressive thickening of the arteries with the length of time during which the men worked underground; this is shown in Table VIII.

TABLE VIII.

Duration of Work Underground.	No. of Men.	Condition of Arteries.		
		A.	B.	C.
(1) Under 1 year	44	21	23	0
(2) 1–5 years	111	6	95	9
(3) 5–10 years	108	7	79	22
(4) 10–20 years	112	6	69	37
(5) 20–30 years	71	4	38	29
(6) 30–40 years	39	0	10	29
(7) Over 40 years	15	0	3	12
Total	500	44	318	138

It is seen that of 44 men who had worked below ground one year or less, no fewer than 21 had normal arteries—that is, 48 per cent.; and those were not only boys, but included men up to 30 years of age. In no other grouping of the cases is it possible to get such a large percentage of normal arteries. It is also noticeable that there is a distinct increase in the amount of thickening of the arteries with the duration of occupation underground.

From this last table it seems evident that work below ground, under the conditions of ventilation shown to prevail, has a definite relation to the prevalence of arterio-sclerosis in coal miners. We believe that it is this arterio-sclerosis, with its subsequent results on general nutrition, which accounts for the increased mortality of coal miners after the age of 55. For although statistics may not show conclusively that miners suffer from diseases of the circulatory system more than men in other occupations, yet it is only to be expected that such an insidious pathological condition as arterio-sclerosis will in many cases fail to be recognized as the initial cause of death.

It has been our experience to meet with many miners who, while not complaining specially of any circulatory disturbances, have the physical appearance, while still on the right side of 60, of having summed up their threescore years and ten; and in many cases we have seen these men dying at or about the age of 60 with all the symptoms of vascular degeneration.

SUMMARY.

1. There is an unexplained difference in the mortality rate of coal miners as compared with other occupied males.

2. The results of the consecutive examination of the circulatory system of 500 coal miners are analysed.

3. It is shown that among coal miners of all ages there is an extraordinary prevalence of thickened arteries; the thickening is confined to the intima in the specimens examined.

4. There is no associated rise in blood pressure.

5. The only significant constant factors are (*a*) the inhalation of air of altered composition, especially the CO_2 content; and (*b*) the absence of daylight.

6. It is suggested that the arterio-sclerosis shown to exist in coal miners is the explanation of the peculiarity in their mortality rate.

DIFFUSE PNEUMOCOCCAL PERITONITIS IN A BOY:

POST-OPERATIVE PARALYTIC ILEUS TREATED BY ANTI-GAS-GANGRENE SERUM: EMPYEMA: RECOVERY.

BY

B. SOUTAR SIMPSON, M.B., F.R.C.S.ED.,

SURGEON, LAWSON MEMORIAL HOSPITAL, GOLSPIE, SUTHERLAND.

SINCE 1926, when Williams[1] drew attention to the uses of anti-gas-gangrene serum in peritonitis and intestinal obstruction, many encouraging results have been described following the use of the serum in such cases. Molesworth[2] rightly sounds a note of caution in accepting such enthusiastic clinical reports of a comparatively new form of treatment. I venture to publish the following account of a case of diffuse pneumococcal peritonitis where anti-gas-gangrene serum had a beneficial effect and the patient recovered from a disease in which the mortality is admittedly very high.

A boy, aged 15 years, who had previously been in good health and had never suffered from any serious illness, was admitted to hospital on May 25th, 1929, with acute abdominal symptoms. He had become suddenly ill five days previously with severe abdominal pain and vomiting. There was no rigor. The pain was spasmodic, increased gradually in severity, and was felt most acutely in the lower abdomen, especially in the right side. From the commencement of the attack the bowels were constipated. No frequency of micturition was noted, but the boy at times complained of pain during the act. At no time did the patient have any cough or chest symptoms. (For the above particulars I am indebted to Dr. W. W. Turner, Lochinver, who recommended the case.)

On admission the patient was in a critical condition. He was very thin, the face was pinched, the expression anxious. The lips and finger-tips showed some cyanosis. The temperature was 102° F., the pulse rate 126, irregular and feeble; the respirations were 24 per minute. The tongue was dry and furred, and the breath was foul. There was no herpes labialis. He complained of severe and continuous abdominal pain, most marked in the umbilical and right iliac regions. There was frequent vomiting of offensive brown watery matter, which was very acid in reaction. The abdomen was moderately distended, immobile, and intensely rigid all over. Cutaneous hyperaesthesia and tenderness were most marked in the umbilical region and the right lower quadrant. The percussion note was tympanitic except in the flanks, where some dullness was present. There was no cough, and nothing abnormal could be detected on examination of the chest. The right tonsil was moderately enlarged and appeared to be slightly inflamed.

Operation.—As a preliminary morphine 1/6 grain and atropine 1/100 grain were given. Anaesthesia was induced with gas and oxygen, and followed by open ether. The abdomen was opened by a right paramedian incision. Much thin yellowish pus at once escaped and was seen oozing from all directions. The pus had a peculiar musty odour, and contained small flakes of lymph. There were no signs of adhesions even in an early stage of formation, the infection being diffuse. The peritonitis was, however, distinctly more intense in the right infra-colic compartment. The caecum, appendix, and subperitoneal tissues were oedematous and injected. The small gut was of a dull red colour, had lost its gloss, and appeared lifeless. The glands at the root of the mesentery were enlarged and inflamed. The peritoneal cavity having been cleansed as much as possible, and the appendix removed, a drain was placed in the pouch of Douglas through a separate stab wound in the mid-line. The original wound was closed, with a small drain in the lower angle.

Pathological Report.—The direct preparations showed many pus cells and numerous Gram-positive diplococci. Inoculated media yielded pure growths of a pneumococcus.

Progress.—Rectal salines and glucose (2 per cent.) were given four-hourly, and on the following day the condition of the boy had improved; temperature 99.4° F., pulse 80–100. On the afternoon of May 27th, about thirty-six hours after operation, he was uncomfortable and restless, and became rapidly worse towards evening. Vomiting recommenced, the abdomen became distended, and no flatus was passed. Enemata were ineffectual. The pulse rate rose to 130; the extremities were cold. It was obvious that a paralytic ileus was present. At 6.45 p.m. 10 c.cm. of anti-gas-gangrene serum "W" (Wellcome) was given intramuscularly. An hour later a little flatus had been passed and the patient was more comfortable. At 9 p.m. 10 c.cm. of serum was given. Shortly afterwards flatus was passed freely and he was much relieved. The vomiting ceased, and during the night he had some natural sleep. The next day the temperature was 99° F., pulse 100. At 10.45 a.m. he was given 12.5 c.cm. of serum. Soon afterwards the bowels moved freely, the motions being dark and extremely offensive. At 6.30 p.m. he was given another 12.5 c.cm. of serum. During the next few days the bowels continued to act four to six times in the twenty-four hours. On June 6th a dose of castor oil was given and the motions became normal.

The general condition improved steadily, although the temperature rose each night to 99° or 100° F. The chest was examined on several occasions without detecting any abnormality. On June 16th he suddenly had a sharp spell of coughing and the respirations rose to 36. A small area of dullness was discovered at the base of the left lung. As the boy was comparatively well and had little discomfort it was decided to wait in order to allow the abscess to localize. However, on June 20th he coughed up several ounces of pure pus. The physical signs in the chest cleared, the temperature and pulse dropped to normal, and he made good progress towards recovery.

On July 15th the temperature again rose, and it was evident that a large collection of pus was forming in the left chest. It was noticeable that there was no cough, and although the temperature gradually rose to 103° F., he had practically no discomfort. On July 20th, under general anaesthesia (gas and oxygen), a portion of the ninth rib was resected in the posterior axillary line, the cavity cleansed, and drainage instituted by the "closed" method. Drainage of typical pneumococcal pus continued for some days. At the end of a week the discharge had practically ceased; the wound was dressed for the first time and the sutures and tube were removed. Healing took place rapidly and without complication.

The patient subsequently made an uninterrupted recovery.

Summary.

The points of interest in this case may be summarized as follows:

1. At the outset the history did not suggest a pneumococcal peritonitis. There was no rigor at the commencement of the acute illness, no diarrhoea occurred, neither was there any herpes labialis. Exact pre-operative diagnosis was not possible.

2. As no demonstrable path of infection existed, the condition appeared to be an "idiopathic" type of the disease, although Fraser[3] makes it clear that primary pneumococcal peritonitis can only occur in the female. In the light of the subsequent history, however, the condition must be regarded as a septicaemia with a small concealed focus in the lung as the primary focus. Barrington-Ward[4] describes a case of pneumococcal peritonitis where a very small hidden empyema, unsuspected during life, was discovered post mortem.

3. Although the peritonitis was diffuse, it was clearly seen at operation that the infection was most intense in the ileo-caecal region.

4. The administration of anti-gas-gangrene serum in its concentrated form proved beneficial when the establishment of a paralytic ileus had rendered the condition apparently hopeless.

GRADENIGO'S SYNDROME FOLLOWED BY COMPLETE RECOVERY.

BY

E. BROUGHTON BARNES, F.R.C.S.Ed.,

AND

C. L. GIMBLETT, M.D., M.R.C.P., F.R.C.S.

GRADENIGO'S syndrome has attracted a considerable amount of attention in recent years, and the following details of a rather unusual case may therefore be worthy of record.

A public school boy, aged 16, had an acute attack of otitis *media* on March 13th. There was a history of discharge from the right ear for a short period, after influenza five years previously. The present attack was preceded by a post-nasal infection on March 9th.

The ear was discharging freely when it was first seen. The temperature persisted in the neighbourhood of 99° F. until March 28th, when it rose to 101° F. There was slight tenderness over the mastoid region, and a Schwartze operation was performed on that day; this revealed a very cellular mastoid, with an extensive cell system passing backward behind the lateral sinus and necessitating a backward continuation of the incision. There was also an infected cell system, which dipped deeply into the back of the petrous bone in front of the sinus. These cell systems were opened up and the whole tip of the mastoid was removed. All the cells contained pus, from which a short-chain non-haemolytic streptococcus was recovered.

Although the wound appeared perfectly healthy and the discharge rapidly became mucoid, the boy *continued* to have a temperature around 99° F. No cause for this pyrexia could be found in the ear, chest, or elsewhere. *Immediately* before the operation and for a fortnight afterwards he complained of pain, neuralgic in character, above and below the right eye. There was no headache.

On April 9th he complained of a fleeting diplopia, and on the following day there was obvious weakness of the external rectus of the right eye; by April 13th paralysis was complete. There was no further neuralgia after this date. The temperature became normal on April 17th, and remained so.

He was discharged home on May 2nd with the mastoid wound healed and the membrana tympani intact. He could then easily hear a 32 double vibrations fork. Some recovery of the external rectus of the right eye was just detectable.

On May 13th he was examined for the diplopia, and it was found that he had an internal squint with almost complete paralysis of the right external rectus and uncrossed diplopia, most marked on looking to the right. There was hardly any vertical displacement of the images. Vision was 6/6 in both eyes, with a +2 cylinder (95 degrees) in the right and a +2.25 cylinder (90 degrees) in the left. In other words, after correction of the hypermetropic astigmatism present, he had full vision with each eye. The fundi and media were normal. The father stated that the eye was "not so much in the corner as it was at first." On looking directly ahead at a small light placed at 6 metres distance, with a Maddox rod before the defective eye, there was between 30 and 40 degrees of measurable esophoria. He could not obtain any fusion of the two images.

Paralysed eye muscles differ from those in other situations in that the defective muscle cannot be kept at rest. The eye muscle is *kept constantly* but partially moving, even if the eye is covered, by the conjugate movements of the two eyes. This very considerably aids its recovery if the nerve is not permanently destroyed, especially in a situation where massage and faradism cannot be applied. This boy was treated by an expert masseuse *twice a week*, between May 21st and July 2nd, with ionization with the continuous galvanic current for five to seven minutes; the pads were soaked in saline, and applied, one between the second and fourth cervical vertebrae and the other directly over the outer conjunctiva, which had been previously anaesthetized by 1 per cent. cocaine solution. The patient tolerated this treatment quite well, and it was followed by interrupted galvanism *in the hope* of stimulating the external rectus muscle fibres. He wore a shade to free him from the disabling diplopia.

His progress was as follows.

May 27th: Hardly any visible squint; 18 degrees of esophoria; single vision with prism, but not without it.

June 11th: There was 12 degrees of esophoria. The first thing in the morning the patient did not have double vision, but it came on by breakfast time. It was decided to try to abandon the shade in the earlier part of the day.

June 24th: The esophoria was *now only* 3 degrees, and the patient left off his shade. Fusion was obtained without any prism.

July 8th: No measurable esophoria was detectable, and there was good binocular vision. The abducent nerve, therefore, took about three months to recover.

We publish this case chiefly for the interest of the complete report of the recovery, which in such cases has not always been fully recorded. It is also noteworthy that the syndrome was associated with an exceptionally cellular mastoid. The syndrome is not of the complete Gradenigo type in that the boy at no stage suffered from headache.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HYPERTROPHIC TUMOUR OF THE SKIN OF THE LEG ARISING IN A CHRONIC VARICOSE ULCER.

THE following case seems to be of sufficient surgical interest to warrant publication.

The patient, a plethoric woman aged 62, the mother of twelve children, had suffered from varicose veins in both legs practically all her adult life. Twenty-five years ago, during her ninth pregnancy, a vein burst on the inner side of the right leg; this

was followed by a large weeping varicose ulcer over the site of the ruptured vein, which since that time had never healed completely. It was treated by hot lint and various ointment applications.

Twelve years ago an ulcer broke out on the left leg, and the ulcer on the right leg became very painful and irritating. She attended the out-patient department of a hospital in London and had Lassar's paste applied weekly. The ulcer on the left leg healed completely, but that on the right leg was only alleviated. Since then she had been treated by her own doctor by hot lint applications.

Nine months ago the ulcer became very painful, irritating, and offensive; at the same time warty growths began to appear round its edges; these extended fairly rapidly in all directions, and bled easily on the slightest injury. The patient has been unable to put the foot to the ground for the last nine months.

On admission to hospital there was a very extensive hard, nodulated growth extending round the whole circumference of the right leg, in the calf, and on to the dorsum of the foot. On the inner surface of the leg were two ulcers extending down to the bone—the site of the original ulcer. The growth was hard, nodular, and friable, bleeding when disturbed. No glands were palpable either in the popliteal space or in the groins. There was a scar of a healed ulcer on the inner side of the left leg and numerous varicose veins. A radiogram showed periostitis of the right tibia and fibula over the site of the tumour. The leg was amputated and healed normally.

The pathological report of a section of the tumour described it as being a papillomatous growth with much round-celled infiltration, but no definite signs of malignancy.

W. DONALD BEDFORD, M.B., Ch.B.,
Resident Surgical Officer, Hertford County Hospital.

SLOUGHING OF UTERUS AFTER COMPLETE INVERSION.

THE following case of complete inversion of the uterus may be worth recording in view of its very unusual features.

A married woman, aged 32, under the care of a certified midwife, was delivered of her third child after an uneventful labour of six hours on July 10th. She described her puerperium as normal, but admitted that the "lochial" discharge had continued for eighteen days, and that she had *become very constipated*. She got up on the tenth day feeling quite fit.

On the eighteenth day after her confinement she suddenly discovered that she could not pass water, and on attempting to open her bowels she felt a large mass pass per vaginam.

When she arrived in hospital she appeared pale and somewhat shocked but she felt no pain. Her pulse was 100, and her temperature 99.6°. She had felt the mass pass through the vagina about two hours before. Previous to that, on the same day, she had attended church and carried out her ordinary duties.

On examination, the uterus, the size of a four months' pregnancy, was seen to be completely inverted and lying outside the vagina. The exposed surface was smooth, shining, greyish in colour, and showed signs of sloughing, accompanied by a strong faecal odour. The openings of the Fallopian tubes were quite obvious. The bladder was distended.

Under a general anaesthetic the uterus was thoroughly cleansed with biniodide solution and saline, and the bladder catheterized. An attempt was then made to reduce the inversion; on this being found to be impossible the uterus, in its inverted state, was pushed back into the vagina, and the vagina packed with gauze wrung out of biniodide solution. The condition of the patient and the gangrenous state of the uterus did not allow of anything else being done then.

Subsequent treatment consisted of vaginal douches of biniodide solution three times daily. A profuse purulent vaginal discharge was present from the first. The temperature continued at 100° for ten days, and then gradually came down to normal. On the eighth day after admission a large gangrenous mass came away from the vagina, which practically corresponded to the whole of the uterus, except for the cervix. From that day the discharge gradually diminished. There was no haemorrhage whatsoever at any time in the course of the illness. On August 30th, five weeks after admittance to hospital, she was discharged quite well.

On examination per vaginam the remains of the cervix, slightly patent, could be felt *in situ* and the pelvic floor in good condition.

This case presents the following very unusual features:

1. The uterus must have become inverted shortly after labour, yet, presenting no signs other than constipation and the continuous red "lochial" discharge, the inversion was not discovered until eighteen days after delivery.

2. Shock was entirely absent until the uterus protruded through the vagina.

3. The case showed little or no signs of actual septic absorption.

4. Sloughing of the uterus, with uneventful recovery.

I am indebted to Dr. Richmond for permission to report this case.

ALEX. WOOD, M.B., Ch.B.,
House-Surgeon, Rochdale Infirmary.

Reports of Societies.

MINOR INJURIES OF THE ELBOW-JOINT.

AT a meeting of the Section of Orthopaedics of the Royal Society of Medicine, on December 3rd, a discussion was held on minor injuries of the elbow-joint. Mr. D. MACRAE AITKEN presided.

Mr. W. H. OGILVIE gave a detailed description of the structure and mechanism of the joint; anatomists defined it as a hinge, and omitted those dissertations on function which lent life to similar studies of the knee or hip. The mechanism of the elbow-joint was identical with that which allowed the eye to move in its bony socket, and by a series of synovial fringes Nature had overcome the problem of the sharp edge. The elbow was primarily designed for use in positions between 110 and 170 degrees of extension, and between half and three-quarter pronation; the pronation position was that in which the forearm was held in all common positions of the arm, and provided the only logical explanation of the carrying angle of the elbow. The position of full extension and full supination in which the carrying angle became obvious was a *wholly artificial one*; the purpose of the carrying angle was to allow the radius to lie in the long axis of the humerus. The position of rest for the elbow was one of slight flexion and rather more than half pronation. The majority of injuries seen in the elbow were due to indirect violence, but, in addition, the elbow region was exposed to direct violence by falls or by blows on the arm raised in self-defence. After illustrating a number of injuries, Mr. Ogilvie spoke in particular of tennis-elbow, the clinical features of which were well recognized. This condition was found in followers of those trades and sports in which the arm was jerked rapidly into full extension while the hand grasped some large instrument. The onset was rarely sudden; the condition became progressively worse with the use of the arm, and an additional symptom was momentary inhibition on lifting small objects such as a teacup. In most cases there was no swelling or other alteration in the contour of the joint, and the x-ray picture was negative. A common clinical type was due to tearing of muscle fibres at their origin from the bone, with, in some cases, separation of the periosteum; but sometimes tennis-elbow could

not be explained by tearing, and was due to internal derangement, similar in its cause to the injuries of the internal semilunar cartilage of the knee.

Mr. P. JENNER VERRALL said that internal derangement of the elbow-joint as a cause of tennis-elbow had appealed to him for a long time, but he had not been able to prove it. He regarded tennis-elbow as being possibly in a number of cases a muscular rupture, but in the majority a combination of circulating toxins and local trauma was concerned. Partial dislocation of the head of the radius was apt to be treated rather lightly and considered a minor disability, but the speaker's experience was that a dislocated head of the radius forwards was a most tiresome matter, and if left displaced caused musculo-spiral neuritis. For fractures of the head of the radius early operation was the only thing worth consideration. He did not regard excision of the head of the radius as a good operation with a movable elbow; he had had a large number of cases in which he had excised the head of the radius in a fixed elbow, but he did not do this at all light-heartedly if the elbow was movable.

Mr. WATSON JONES pointed out that elbow injuries were most common and significant in the second decade of life, for the elbow of the young adult was very susceptible to injury. He pleaded for the keeping of constant records of the range of returning movement following different treatments; a study of these might not justify the treatment adopted in a particular case, and it was very easy to be misled as to range of movement if one relied only upon unaided observation from time to time, or even upon the patient's description. Dealing with fractures of the head of the radius, he said that the end-results in his cases showed that these apparently innocent and trivial injuries of the head of the radius had a prognosis which was worse than that of supracondylar fractures with gross displacement. Even in cases where there was no displacement his figures showed a perfect result in supracondylar fractures in 100 per cent. of cases, whereas with fractures of the head of the radius, also with no displacement, a perfect result was only obtained in 93 per cent.

Mr. WHITCHURCH HOWELL said that tennis-elbow was the result of bad tennis, and very seldom occurred in a professional player; when it did, the player was usually not a young person, but someone of arthritic type in whom, perhaps, some latent sepsis in the muscular tissues had been associated with trauma. Certain cases of tennis-elbow were due to a contraction of the extensors and a pinching of the cutaneous nerve in that region.

Mr. R. C. ELMSLIE remarked that continuous tennis-elbow did not come on acutely, but so gradually that it was difficult for the patient to say exactly when the condition arose. The patients were often over the age of 35, and were continuing to play hard tennis when others had desisted. There were some very characteristic symptoms, such as the position of the tender spot, which was absolutely over the radio-humeral joint. In his opinion, true tennis-elbow was brought out in tennis by a forehand drive, a position in which the hand was supinated and the wrist fully extended. He always excluded from the category of tennis-elbow those cases in which there was definite evidence of arthritis of the elbow-joint; in these there existed a definite pathological cause, which was absent from ordinary tennis-elbow. As to the physical treatment of injuries of the elbow-joint, particularly in young people and children, the best functional result was obtained by normal natural processes without assistance. The child's own movements would restore function more rapidly than any assistance was likely to do. Unfortunately, the present generation expected early massage and movements, and the only solution of the difficulty he had found was to give to those performing the massage the kind of instruction which had led one of them—a particularly intelligent person—to remark, "What you really mean is that you want me to pretend to be doing a lot and really to do very little."

Mr. W. H. TRETHOWAN said that there was nothing more constant in its clinical picture than tennis-elbow; it was a traumatic synovitis of the radio-humeral joint. Why, then, imagine various pathologies? It was quite well known that certain bone-setters did cure tennis-elbow by manipulation; in other cases it was equally evident that they did not. In eight intractable cases he had explored the joint; he had found Osgood's bursa in some of them, not in others. Osgood's bursa was nothing more than an extension of the synovial membrane of the radio-humeral joint. In these eight the only abnormality he had discovered was that all of them, at both the front and back of the joint, had injected synovial fringes. With the removal of the fringes restoration of normal function in time became complete.

Mr. ROCYN JONES said that in certain cases of tennis-elbow there was definite limitation of movement, and in these Mills's manipulations proved very valuable. One lesion of the elbow-joint often found was a fissure fracture of the head of the radius, due to pitching forward on the outstretched hand.

Dr. PHILIP FIGHOM, speaking as one in charge of a massage department, said that many cases were sent to his department with direct instructions to give massage, simply because the *x*-ray picture had shown that there was no fracture about the joint; these, however, were dangerous cases, and should receive far more careful attention. He had seen cases which in their early stages had even been mismanaged reach a perfect result by active movement of the elbow-joint, which gave nearly 100 per cent. good results.

Mr. MACRAE AITKEN, from the chair, said that if time permitted he was quite prepared to disagree with nearly everybody who had spoken on tennis-elbow. Even Mr. Ogilvie had stated that the condition was invariably on the outer side; but, in fact, there was pain of a very similar sort associated with the origins of the muscles arising from the internal condyle. There were cases which were directly relieved by the use of a pad and strap; there were others which no pad and strap he had been able to devise could relieve, but which on manipulation "went flick," and the cure was complete. He agreed about treatment by natural movement, provided the patient was restrained from indiscretions.

Mr. OGILVIE, in reply, said that he thought it was a duty when examining a case to try to translate the history and physical signs into terms of microscopical pathology. If it was a case of blood effusion, the treatment was rest; if the microscopical section showed young connective tissue cells and blood vessels, the treatment was limitation of movement combined with pressure; here, he thought, a small pad over the tender spot and a strap did a great deal of good. If the microscopical condition showed connective tissue with no cells and no blood vessels, then Mills's method of manipulation would cure all cases except those of an arthritic type.

SHAPE OF THE PELVIS.

AT the meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on November 15th Dr. KATHLEEN VAUGHAN read a paper on maternal mortality and its relation to the shape of the female pelvis.

Dr. Vaughan said that her experience in Kashmir had led her to suggest that civilization created conditions which resulted in the deforming of the pelvis in women. Caesarean section was as common in Kashmir as in China among women of the better classes who suffered from the purdah system. Boatwomen in the same towns, engaging in heavy work on a coarse but sufficient diet, did not suffer from difficult labours. Similarly, the African negress in a kraal had an easy labour, while in an American city obstetrical complications occurred owing to the poor hygienic conditions under which she then lived. The report of Dr. Janet Campbell had shown that the highest rate of maternal mortality was to be found in industrial centres. Dr. Vaughan contended that the fundamental cause was that the shape of the child's head and the mother's pelvis did not agree; in her opinion the capacity of the pelvic inlet depended more upon shape than upon size. Variations in shape in a number of pelves of different races were discussed by the speaker, and three types were defined. The circular type, in which the whole of the body of the first sacral vertebra was outside the inlet, was found in

certain native races, and in pelves in Ur and Ancient Britain. In the second type, the antero-posteriorly contracted or rickety variety, the upper part of the sacrum and the fourth and fifth lumbar vertebrae helped to block the available space; this type was found among Europeans and Egyptians. The third type was flattened from side to side, as in osteomalacia and the pelvis of the ape. Dr. Vaughan said that the two last types must be considered pathological in women, for the foetal head was circular, and a larger head could be born through a circular inlet than through any other form having the same boundary measurements. X-ray examinations had shown that the ends of an oval pelvis were not occupied by the child's head at birth. In the European the head descended in a screw-like manner because the three largest diameters of the pelvis were situated in different pelvic planes, whereas in the round pelvis all the diameters of the three planes were equal with movable sacro-iliac joints, and labour was quick and easy. After describing various postures adopted in native labours, Dr. Vaughan emphasized the importance of the sacro-iliac joints, which were well developed in the circular pelvis of the negress, South Australian women, and those who still led natural lives. Civilized women did not use these joints, except in games and gymnastics, and the shape of the normal pelvis was altered by the adoption of an indoor sedentary life, associated with deficiency of sunlight and vitamin D. The speaker added that the problem of maternal mortality should be attacked by ensuring proper development of the pelvis in little girls in their earliest years, and not by making elaborate provision for abnormal childbirth.

TRAINING AND EMPLOYMENT OF MIDWIVES.

A MEETING of the North of England Obstetrical and Gynaecological Society was held at Sheffield, on November 22nd, with the president, Dr. G. W. FITZGERALD (Manchester) in the chair. Professor D. DOUGAL (Manchester) opened a discussion on the report of the Departmental Committee on the *Training and Employment of Midwives*.

Professor Dougal pointed out that the report contained matters of far-reaching importance, not only to those engaged in the teaching of medical students and midwives, but also to all concerned with the improvement of obstetrical practice generally. The various sections of the report were outlined and commented upon. Hearty agreement was expressed with the view taken that the doctor responsible for the ante-natal supervision should also be the doctor who might be on call or in attendance during labour and the puerperium. The speaker mentioned that the maternity scheme followed closely on the lines of that drawn up by the British Medical Association, and the opinion was expressed that it was perfectly sound. He considered the effect that the introduction of such a scheme would have on the supply of teaching material for medical students and midwives. The Government Actuary Department had stated that maternity benefit was at present payable in about 80 per cent. of the total confinements, and that of the remaining 20 per cent. about one-half occurred in families of equivalent economic status. When a midwife and a doctor were provided for every mother coming within the scheme it was evident that the number of normal cases attended by any maternity hospital would be very much diminished. There would be a certain number of necessitous cases, but these would not be very numerous, and financial help would be given to them by local authorities. With regard to the training of midwives the suggestion of a preliminary test of general education was warmly welcomed. Post-examination experience before registration was also considered helpful, but only if it was obtained with up-to-date midwives or institutions. The practical difficulties of holding a clinical examination were mentioned, and a suggestion was made that a few pregnant women ought be present at the oral examination, so that the pupil could be tested on the signs of pregnancy and the methods of abdominal examination. The paragraphs dealing with the use of drugs by midwives were discussed, the opinion was expressed that these women should not be allowed to give sedatives, but that there was no objection to their being allowed to give hypodermic injections of pituitrin or ergot under the same restrictions as existed at present with regard to the administration of the latter drug by mouth. On the question of the supply of midwives it was suggested that the midwifery practice in certain of the poorer districts should be conducted by whole-time salaried midwives, employed either by a maternity hospital or by a local authority, and that suitable hostels should be provided to accommodate them. A much better class of midwife would be attracted by such means, and proper facilities would be available for bathing and the sterilization of clothing. In addition, the centres would supply suitable clinical material for training purposes. The qualifications suggested for supervisors of midwives, the appointment of an independent legal assessor to the Central Midwives Board, and the proposal to give that body power to subpoena witnesses and to take evidence on oath, were generally approved. The clauses dealing with the approval and inspection of training institutions, the arrangement of the curriculum, and the formation of an advisory committee and an examinations board were discussed, and a definite pronouncement made in favour of the views expressed by Dr. Fairbairn and Mrs. Bruce Richmond.

Professor MILES PHILLIPS (Sheffield) agreed with the comments made; he believed that action on the lines of this report would improve the status of midwives. The idea of midwives living at a hostel with baths, regular meals, holidays, and adequate pay for their arduous work appealed to him. He doubted if a clinical examination was practicable, but thought that if a few patients were present at the oral examination, and some candidates were examined on them, this would act as a stimulus and improve the general standard. Post-examination experience would be of value; it was insisted on in one country for medical students, and it might help to provide staff nurses in maternity hospitals. He especially supported Dr. Fairbairn's remarks, and thought that a considered opinion from the North of England Society might influence the authorities before they took a decision.

Dr. F. H. LACEY (Manchester) also agreed entirely with Dr. Fairbairn's reservations. Large ante-natal clinics should be in close touch with large maternity hospitals, and a report on an ante-natal examination be forwarded to the doctor who would be in charge of the confinement. If a panel of practitioners was formed to conduct a maternity service they should be required to have special experience such as was necessary to obtain arsenical preparations at the special rate in venereal disease work. He approved the test of general education and of a modified clinical examination. He doubted if there really was a shortage of cases and if the best use was at present being made of the clinical material. There were considerably more cases in the Manchester Union hospitals than were needed for the number of pupil midwives trained there, and since he could imagine certain disadvantages in training medical students and pupil midwives together, he suggested that the former might receive their education in maternity hospitals and the latter in union hospitals. With regard to post-certificate training he advocated one month's residence in a maternity hospital every four or five years. He thought that limitation of the number of cases, the prescribing of holidays, the provision of reliefs, and the control of hostels conducted by municipal authorities or maternity hospitals would be of great benefit.

The report was further discussed by Drs. LEITH MURRAY and J. E. GEMMELL (Liverpool), Dr. W. W. KING (Sheffield), and Dr. J. W. BURNS (Liverpool), and the following resolution was passed:

> This society is of opinion that the report of the Departmental Committee on the Training and Employment of Midwives is a valuable contribution to the problem of providing a better maternity service and reducing the present high incidence of puerperal mortality and morbidity; but feels that the proposal contained in the report to limit the power of the Central Midwives Board and to give the Minister of Health the sole responsibility of approving and inspecting training institutions and teachers, and of laying down the curriculum of training would, if adopted, be prejudicial to the teaching and practice of midwifery in this country.

The Blood Cholesterin in Pregnancy.

Mr. P. MALPAS (Liverpool) read a paper on the cholesterin content of the blood in pregnancy, and described an attempt to elicit the normal cholesterin content of the blood of pregnant women, and its possible relationship to the course of the puerperium. The inquiry arose in the course of a search for a method of estimating the resistance of pregnant women. MacAdam and Shiskin's work seemed to show that the blood cholesterin content was of value as an index of the degree of immunity to post-operative sepsis in cases of urinary abnormality. The method of estimating the blood cholesterin was that of Leiboff, and the estimations were carried out on whole blood. In twelve cases estimations were repeated at monthly intervals from the thirtieth week until term. In a further thirteen cases single estimations were made at term only. The series of Gardner and Gainsborough had been published during the course of this work. While realizing that the number of cases was small the results were so negative that they appeared to justify the conclusion that there was no fixed level of cholesterin in the blood in pregnancy, but a rising curve of hypercholesterinaemia from the thirtieth week onwards to term, with a sudden and temporary drop at the onset of labour. It was not possible to fix any arbitrary standard of normality at any given period of gestation, there being wide differences in different patients. There did not appear to be any relation between the cholesterin content of the blood at term and the degree of immunity to puerperal infection, or, rather, the former was of no value as a clinical index to the latter. A possible relation of the cholesterin value to the degree of parity was suggested. The administration of quinine had no effect on the cholesterin value of the blood.

Dr. LEITH MURRAY considered that more work was necessary on the immunity of pregnant women. Dr. A. A. GEMMELL compared the blood cholesterol curve in pregnancy as presented by Chauffard with the curve of the bactericidal power of the blood in pregnancy recently reported from Edinburgh, and suggested a possible significance from the fact that they were so very similar. Mr. MALPAS, in reply, said that he thought curves of all metabolic processes in pregnancy and the puerperium were of the same type.

Radium Treatment of Uterine Neoplasms.

Professor MILES PHILLIPS (Sheffield) showed a specimen of a uterus removed after radium treatment for squamous carcinoma of the cervix in a multipara, aged 64, in whom the menopause had occurred twenty years previously. The portio was eaten away and lay flush with the vaginal vault. There was no induration of the broad and utero-sacral ligaments, and cystoscopy did not reveal any bladder involvement. The patient had been given a full Heyman treatment, and at the third application it was noted that the growth had disappeared and the patient had a normal atrophic cervix. Two months later the patient had an operation for cholecystitis with suppuration in the upper abdomen and died; the specimen shown was removed after death. The kidneys and ureters were found normal; there were no enlarged pelvic glands, and the genital organs were removed intact without any difficulty. Such sections as had been cut did not show any cancer cells.

The PRESIDENT said that, in his experience, "cures" by radium were few. Dr. W. W. KING (Sheffield) asked if there was any induration in the broad ligaments; he had known cases in which considerable difficulty was experienced in removing uteri after treatment by radium, but he thought that possibly modern methods of screening obviated this.

Professor D. DOUGAL (Manchester) mentioned a case of diffuse adenomyoma of the uterus which had been treated by radium, but since bleeding was still persisting when he saw her he removed the uterus. The parametria were markedly indurated in this case, rendering panhysterectomy very difficult. Professor PHILLIPS said he could not give a definite reply as to the induration of the parametria, but the pathologist reported that removal of the genital organs was "easy."

GYNAECOLOGY IN A GENERAL HOSPITAL.

A MEETING of the Section of Obstetrics of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on November 15th, when the president, Professor A. H. DAVIDSON, read a paper on three years' work in the gynaecological department of a general hospital. The paper embodied a report of the work done and the results obtained in the gynaecological department of Dr. Steevens' Hospital, Dublin, for the period June, 1926, to June, 1929.

Professor Davidson said that 535 patients had been admitted to the hospital in that period, of whom 505 had been operated upon; 7 deaths had occurred—a percentage mortality of 1.38. There had been 150 dilatations of the cervix; 120 curettings; 130 Gilliam suspensions of the uterus; 311 total, 3 subtotal, and 10 Wertheim hysterectomies; and 85 operations on the Fallopian tubes, including 22 salpingostomies. Rubin's insufflation test was performed ninety times, and iodized oil was injected on fifteen occasions. There were 22 cases of prolapse of the uterus for which shortening of Mackenrodt's lateral cervical ligaments was employed; 65 colpo-perineorrhaphies; 50 amputations of the cervix; 30 trachelorrhaphies; 40 radical cures of cystocele by the bringing together of the torn bladder pillars; 6 cases of bladder fistula, 5 of which had been cured; 8 Caesarean sections; 40 appendicectomies; and many minor and miscellaneous operations. Professor Davidson mentioned that there were eight gynaecological beds, with two operating days in the week; the dispensary was attended last year by an average of 50 patients per week, and the average number of days in hospital for each patient was eleven. Patients with simple abdominal conditions were allowed out of bed on their eighth or ninth day, and left hospital on the twelfth or thirteenth day; each patient was told to report at regular intervals in order to keep a follow-up of after-results. During the three years reviewed there were 90 cases of sterility; of these, 37 were due to pelvic infection with occluded tubes, 17 to underdevelopment of the uterus with associated conditions, 12 to cervical infections (erosion and ectropion) and endometritis, 18 to backward displacements of the uterus, and 6 to infertility of the male. Of the 37 cases with blocked tubes pregnancies were obtained in 6 cases, in 3 cases following double salpingostomy and in 3 cases where some obstruction was blown out of the tubes by the Rubin test. In one case pregnancy followed the therapeutic use of iodized oil in the tubes. The cure by amputation or trachelorrhaphy of infected cervices was followed by pregnancy in five cases. In 70 cases of backward displacement of the uterus the symptoms and the results of the Gilliam subperitoneal suspension were analysed. Backache, present in 29 cases, was cured in 20 and relieved in 6; menorrhagia, present in 30, was cured in 18 and relieved in 8; dysmenorrhoea, present in 16, was cured in 13; pain in the side, present in 25, was cured in 18; dyspareunia, present in 5, was cured in 5. Of the 10 Wertheim hysterectomies for cancer of the cervix there was a primary operative mortality of 3 (30 per cent.); two patients died within 18 months, one after 2½ years, and four were still alive and well, three of them for a period of three years.

Dr. BETHEL SOLOMONS agreed that the follow-up of patients was a necessary adjunct to any clinic. He had been most unfortunate in acute and subacute cases of gonorrhoea treated by diathermy; the more chronic forms were comparatively easily treated by other methods. He had no doubt that inflation of the tubes produced a therapeutic cure of sterility. He did not agree that salpingostomy at the isthmial and interstitial portions of the tube was hopeless; the prognosis was not good, but his isolated successes had encouraged him to persevere.

Dr. R. M. CORBET thought that in parametritis diathermy was a little quicker in clearing up subacute infections than the douche method. Dr. D. J. CANNON said he never operated on a sterility case until he had performed the Hubner test. He referred to the difficulty of estimating the results in this test, and mentioned a recent case in which he had performed division of the cervix. Dr. NIXIAN FALKINER thought the president's results in sterility cases had been particularly good, as also the results in the

Gilliam operation. Dr. J. S. ASHE was glad that the use of plugs had not been altogether abolished. He mentioned the case of a woman whom he had recently delivered after fourteen years' sterility, and said that he had treated the inflammation by the use of drugs and plugs.

The PRESIDENT, replying, said he had not meant to overstress diathermy treatment, since he was not yet in a position to judge. The third case of chronic gonococcal endocervicitis in which he had tried diathermy treatment had improved, but he thought it quite likely that this improvement was only temporary. The cases of transplantation of ovaries were autotransplants, one having been undertaken in a case of salpingo-oophoritis. He mentioned a recent paper by a London worker who had carried out experiments on animals, removing ovaries at intervals of two weeks and transplanting the autografts. In every case the grafts had died, not one being alive at the end of four months, and this seemed to be against the technique of transplantation of the ovaries. In performing Huhner's test it was necessary to get the specimen quickly. The number of cases in which posterior division of the cervix had proved unsatisfactory had been so great that he did not think the operation justified.

Radiography in Obstetrics.

Dr. FALKINER read a note on two obstetrical cases in which the diagnosis had been confirmed by *x*-ray examinations. The first patient, a primigravida, was noted at the thirty-fourth week to have an abnormal mass at the fundus, which was tender on palpation at the thirty-seventh week left little doubt of the diagnosis of a hydrocephalic infant presenting as a breech. This was confirmed by an *x*-ray picture. The patient was delivered at term, the emptying of the fluid being simplified by the presence of a spina bifida: through this opening a metal catheter was passed into the ventricles, the fluid draining away and the skull collapsing. An *x*-ray picture was taken to show the catheter in position. The second was a case of compound presentation occurring in a primigravida with a normal pelvis, and consisting of a foot, hand, and head. The diagnosis was partly made by palpation and rectal examination, since the foot could be easily felt per rectum; an *x*-ray photograph showed that a hand was also involved. The treatment consisted in correcting the presentation and inducing labour. This proved successful in the end, but the malpresentation recurred during the labour, and it was not till the first stage was well advanced that the head could be induced to remain as an uncomplicated vertex; delivery was completed by low forceps. A live child was born; it appeared normal in every way, and had continued in excellent health. Dr. T. G. HARDMAN demonstrated the pictures by means of slides which he had prepared.

LINITIS PLASTICA.

THE Manchester Pathological Society recently held the opening meeting of the current session, and Mr. GARNETT WRIGHT delivered the presidential address, taking for his subject linitis plastica.

Mr. Garnett Wright related how he had operated on two cases of this disease; at the time of operation he had considered them to be undoubted cases of cancer of the stomach, and he had performed a partial gastrectomy on both. He was surprised in each instance to receive a preliminary pathological report stating that the condition was one of extensive fibrosis, chiefly affecting the submucous layer of the stomach, and showing no sign of malignancy. The first patient died shortly after the operation, and the second died nine months later from secondary growths in the peritoneum. The speaker said that Brinton had first given a clear and full description of the disease; he had considered it an atypical form of cancer in which there was an excess of fibrous tissue strangling the invading epithelial growth. Mr. Garnett Wright added that it was possible to demonstrate the carcinomatous nature of the disease by staining the epithelial cells with mucicarmine. Most of the patients who had been followed up had died from carcinomatous metastases.

Professor SHAW DUNN showed an interesting series of microscopical sections of linitis plastica stained with mucicarmine.

Reviews.

THE DIAGNOSIS AND TREATMENT OF SYPHILIS.

Syphilis,[1] by CHARLES C. DENNIE, is exactly what it is stated to be—namely, a monograph of some 300 pages of convenient size, suitable for the general practitioner. The author is nearly always dogmatic, but here and there he is inclined to carry dogmatism to excess. For example, when he states that the *Sp. pallidum* cannot penetrate intact mucous membrane he is directly contradicting the experimental work of Brown and Pearce; in any case, it must be difficult to decide whether a given mucous membrane is intact or not.

The chapters on the pathology of syphilis, classifying it in the four stages of invasion, infiltration, resolution, and cicatrization, are quite the best in the book. The description is clear and simple, and better than that found in most textbooks on the subject. There follows an account, on fairly stereotyped lines, of the various manifestations of syphilis in its different stages and different parts of the body, and cardio-vascular disease is accorded the importance it deserves but does not always receive. In discussing treatment the author presents his material in a curious sequence, dealing with the Swift-Ellis-Ogilvie intraspinal treatment, about which he is evidently enthusiastic, and with tryparsamide and malaria before he comes to the use of arsenobenzol, bismuth, and mercury. The routine "course" laid down is extremely thorough, but as it consists of no fewer than thirty-eight separate injections of arsenobenzol, bismuth, and mercury, and occupies four months, it seems unnecessarily complicated and to demand overmuch of the patient's time and patience. The course might have been set out in tabular form with advantage.

In the course of the work Dr. Dennie brings out a number of important points which are often overlooked or insufficiently stressed—for example, the mistake of applying antiseptics to the primary sore until the diagnosis is made; on the other hand, he lightly dismisses jaundice, the bane of arsenobenzol treatment, and evidently has little fear of arsenobenzol dermatitis. Many syphilologists would regard 900 grains of potassium iodide a day as rather excessive, and few would care to carry out as many cerebrospinal fluid examinations as the author recommends. A few minor errors have crept in, such as the use of "labiae" for "labia," and "intra-vertebral" for "inter-vertebral," but these will no doubt be corrected in a future edition. There is no index. Dr. Dennie has written an excellent book, and the concluding chapter on "Public health and syphilis" might with advantage be issued in pamphlet form to the public.

FACIO-CERVICAL SURGERY.

MR. HAMILTON BAILEY has reprinted some of his published articles to form a readable little book of eighty-six pages. There are fifty illustrations, and the essays deal with branchial cysts and fistulae, thyroglossal cysts and fistulae, submaxillary calculi, and facial carbuncle. The author must have been hard put to it to find a title for such a mixed bag, but he finally compromised with *Branchial Cysts, and Other Essays on Surgical Subjects in the Facio-cervical Region*.[2] On all of these interesting subjects he writes in a practical straightforward way. The sections dealing with branchial cysts and fistulae present a clear picture in quite a short space, though room might have been found for a little elementary morphology. The author explains how an aspirating needle may be used to distinguish between a tuberculous abscess and a branchial cyst, though diagnosis should be possible without this "confirmatory test." For the treatment of branchial cysts he advises complete excision, and in a short chapter describes the operative technique. Sistrunk's operation for thyro-

[1] *Syphilis: Acquired and Hereditary Syphilis.* By Charles C. Dennie, B.S., M.D. Harper's Medical Monographs. New York and London: Harper and Brothers. (Demy 8vo, pp. xii + 301; illustrated 10s. net.)

[2] *Branchial Cysts, and Other Essays on Surgical Subjects in the Facio-cervical Region.* By Hamilton Bailey, F.R.C.S.Eng. London: H. K. Lewis and Co., Ltd. 1929. (Cr. 8vo, pp. viii + 85; 50 figures. 5s. net.)

glossal fistula is described in some detail, though the author does not tell us whether he has practised it. In this method no attempt is made to isolate the suprahyoid part of the tract, but the surrounding tissues are "cored" out *en bloc* as far proximally as the foramen caecum. The last chapter deals with facial carbuncle. Ligature of the angular vein was performed in four patients, of whom three recovered. It is true that intravenous mercurochrome and magnesium sulphate locally were also used, but the operation is perhaps worth trying in some of these desperate cases. The book is well produced; it may be read in an hour, and most surgeons would learn something from it. The index is good and the illustrations are clear, though the single coloured plate scarcely justifies its inclusion.

EPILEPSY.

DR. PHILIPPE PAGNIEZ'S book *L'Epilepsie*[3] can be heartily recommended to all who are engaged either in research upon epilepsy or in the treatment of epileptic patients, for it is an excellent brief review of recent additions to our knowledge of the subject. The author begins by describing the experimental production of convulsions in animals by various methods, and the application of the experimental method to the study of human convulsions. He then discusses the pathological anatomy of epilepsy and the physiological conceptions of the nature of a fit which have been proposed. Metabolic abnormalities of great diversity have been described as occurring in epilepties, and Dr. Pagniez gives a good, if somewhat undiscriminating, account of these, and also of the evidence in favour of the view that anaphylaxis may be a precipitating cause in some patients. His discussion of the toxicity of the body fluids in epilepsy has special interest, as it is in this field that his own experimental work has been carried out. He claims to have demonstrated that the blood serum of epileptics possesses the property of producing convulsive phenomena in guinea-pigs when injected into the carotid artery, and that the toxicity of the serum waxes and wanes according to the relationship between the time of its withdrawal and the occurrence of the convulsion in the patient. Dr. Pagniez discusses the role of the ductless glands in epilepsy, but considers that there is little evidence that endocrine disorders are of any etiological importance. The discussion of treatment occupies approximately one-fifth of the book, and includes a well-balanced consideration of the value of a ketogenic diet, and a survey of what may be accomplished by the bromides, boric derivatives, and luminal.

HOW TO STUDY.

WHEN a student first enters upon a college or university course he or she certainly needs some guidance as to methods of study. It is true that some training in appropriate methods, and some exercise of them, should have been part of the student's experience in the secondary school, but, in fact, these are not universally and effectively afforded there. So far as hints on good study methods can be derived from a book, recourse may well be had to the short *Introduction to Efficient Study Habits according to the Laws and Principles Governing Economical Learning*[4] by MAUDE BLANCHE MUSE, Assistant Professor of Nursing Education, Columbia University, New York. The book contains an "annotated bibliography of the more recent publications on how to study," and it is somewhat surprising to an Englishman, though probably not to an American, that there should be so many such publications noted, and that they should range from booklets of 42 pages to volumes containing nearly 500. It is evident from these references and from the book now under review that there is growing up in the United States a literature on this subject with a technical jargon and phraseology of its own. Phrases like "mind-set," "study-sets," "reference assignment," and others, may lend a kind of quasi-scientific or technical appearance to the reading, but, to an Englishman at any rate, they obscure rather than elucidate the thought, and do not ease perusal. It is probable that a supervised introduction to the practice of private study during the last year or two of school life, together with personal advice and help from the teacher or director of studies at college or university, are the best means of acquiring correct methods, and indeed most of the apt individual illustrations given in Miss Muse's book show how useful and effective such means may be. A textbook or treatise on the science and art of studying may, however, be of use to some, and this volume may therefore be commended as good in its place. It is of the vademecum textbook variety rather than the treatise, but, as its full title promises, it attempts to stress the psychological principles which underlie each study method advocated. The meaning and true objects of study are set forth, and among these is one indicated by the quoted remark of a student at the end of her first year, "The chief thing which college has done for me is to upset many of my pet theories and beliefs." As Mr. Rudyard Kipling said in a recent address, "if people thought, it might lead to a change of opinion; so it is not done." Certain laws governing economical learning are then enunciated, and the importance and influence of first impressions, intensity or vividness of presentation, and of the frequency and duration of periods of review or repetition are dealt with. There is a chapter on efficient study techniques, by which is meant right methods of note-making and note-using, of reading both for study and for reference, and of final preparation for examination. Finally, some specific rules are laid down, and some questions given for class discussion. Much of this may be found helpful and suggestive. Incidentally, a reference to "conditioned reflexes" in connexion with educational methods is made, and it would be useful to have from some experienced educator an exposition of their place and best use in pedagogy.

WESTMINSTER HOSPITAL REPORTS.

THE twentieth volume of the *Westminster Hospital Reports*,[5] edited by Mr. STANFORD CADE and Dr. DONALD PATERSON, covers the interval since the nineteenth volume, which appeared in 1924, and therefore contains the medical, surgical, obstetrical, and pathological reports for the five years 1924 to 1928. Among these Dr. J. A. Braxton Hicks's accounts of the post-mortem examinations, the pathological specimens added to the museum, and, with Dr. F. D. M. Hocking, of the work of the John Burford Carlill laboratories, are notable for the amount of work done and the information provided. There are, in addition, ten previously unpublished papers by members of the staff, beginning with a well-illustrated article on pneumo-radiography by Sir James Purves-Stewart, the senior physician. Dr. Braxton Hicks records a case with very numerous calcified *Cysticercus cellulosae* cysts in the brain, and Mr. Rock Carling, a former editor of these *Reports*, gives his encouraging experience of periarterial sympathectomy for Raynaud's disease, acrocyanosis, and intractable ulcers. Six cases, complete with necropsies, lead Dr. Donald Paterson to the conclusion that progressive spinal muscular atrophy of infants (Werdnig-Hoffmann paralysis) is one and the same as Oppenheim's amyotonia congenita pathologically, but different in its clinical features. Drs. Dore and H. T. Barron record a remarkable example of mycosis fungoides; the treatment of six cases of lymphadenoma by x rays is reported by Dr. F. M. Allchin; and Mr. Rock Carling and Mr. Stanford Cade tabulate 180 cases of malignant disease treated by radium. Mr. A. F. MacCallan writes on cataract, Dr. H. A. Dunlop on the effect of ether on the action of adrenaline on the circulation, and Dr. Adolphe Abrahams on the influence of exercise on the rate of the heart.

HEBERDEN'S "INTRODUCTION TO THE STUDY OF PHYSIC."

DR. LEROY CRUMMER has done well to publish, with many additions and in an attractive format, his article in the *Annals of Medical History* of December last on *An Introduction to the Study of Physic*[6] by WILLIAM HEBERDEN the elder. The manuscript, certainly in the beautiful hand of the author of the famous *Commentarii de Morborum Historia et Curatione*, was picked up by DR. LEROY CRUMMER in "a little shop in the South of London, more or less famous for its 'curiosa' and oddments of the printed page," and has now for the first time been printed without change or emendation. This volume contains, in addition to the *Introduction*, William Heberden's classical account of angina pectoris, entitled "Some account of a disorder of the breast," delivered at a meeting of the Royal College of Physicians in 1768, but not published until 1772. Dr. Leroy Crummer provides an interesting appreciation of Heberden, in which he suggests that the reason why his *Commentarii*, though completed in 1784, were not published until after his death in 1801, was that he wrote them for his sons, and, as an example of his modesty, mentions that he declined the appointment of physician to the Queen, and recommended Dr. Letherland, "a man of deep and very extensive learning, but of retired habits." The *Introduction* was probably written during the latter part of Heberden's Cambridge life or early in his London period (1744–55), when medical education was just emerging from the apprenticeship stage, and a few hospital physicians were beginning to give clinical instruction to personal pupils—a system which soon developed into the nepotism so fiercely and successfully attacked by Thomas Wakley in the *Lancet* at a much later date. Heberden's short chapter "of surgery" was written at the time when the surgeons were parting company *from* the barbers and were practising a handicraft rather than a profession. The *Introduction* contains much of the author's experience in regard to medical education and to the literature then available to the student, a hundred and fourteen texts being mentioned, and the study of the history of medicine is recommended with the help of the works of Daniel Le Clerc and John Freind. Like all the books coming from the firm of P. B. Hoeber, this interesting work is well got up and provided with admirable illustrations.

NOTES ON BOOKS.

Clinical Methods: A Guide to the Practical Study of Medicine, by Drs. H. RAINY and ROBERT HUTCHISON, which first came out in 1897, has long been a familiar friend of clinical clerks. After eight editions it has now entered its eighty-seventh thousand,[7] and the name of Dr. DONALD HUNTER appears on the title-page in place of that of the late Dr. Rainy. Dr. Hutchison thus remains as the senior and original author or editor of two extremely popular medical books—this and *The Index of Treatment*. That the ninth edition has been thoroughly revised and brought up to date is obvious, and in connexion with this the services of colleagues have been obtained in special sections, such as those dealing with the eye, the nervous and circulatory systems, and bacteriological investigation. Among the three new plates there is one showing reticulocytes, which is accompanied by an account of the method of *intra vitam* staining. In the directions about taking the arterial blood pressure attention is drawn to the "silent gap" which may occur in high blood pressure, and the need, therefore, when using the auditory method, of always raising the pressure in the armlet far above the point where the sound disappears. Long experience in teaching has ensured a perennial demand for this handy volume.

Professor VICTOR H. SEARS'S little book on *Full Denture Procedure*[8] is of a more mechanical nature than the dental literature generally reviewed in these columns. We cannot, however, help being impressed by the author's minute attention to detail. He shows the true professional spirit; nothing is too much trouble if it offers a hope of helping the patient to secure a full artificial denture which will remain stable. Perhaps we may venture to suggest that a flat mill would overcome some of the difficulties.

C. E. LIM'S Laboratory Manual of the Division of Bacteriology, Peking Union Medical College,[9] is exactly what its title suggests. It is replete with useful information, conveniently arranged and well indexed. It will be appreciated by both student and teacher.

Income Tax Simplified[10] is a useful little publication which endeavours, within the limits of some seventy pages, to give a condensed statement of the rules to be followed in making income tax returns and of the allowances to be claimed. A disproportionate amount of space seems to us to be devoted to dealing with farm profits, and we doubt whether the lavish use of leaded type adds much to the clarity of statement. The booklet appears to be written in the main as an aid to students of accountancy, but should be useful as a means of assistance and reference to business and professional men.

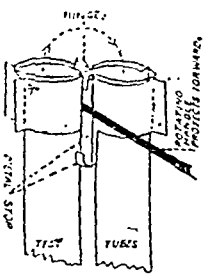
PREPARATIONS AND APPLIANCES.

A DOUBLE TEST TUBE HOLDER.

DR. D. A. HERD (Liverpool) writes: I desire to introduce a small device to facilitate the examination of excreta. It consists of a pair of metal clips united by a hinge. Attached to the right clip is a small metal "stop," which prevents the test tubes touching each other. Projecting forwards from the left clip is a 10-in. rotating handle, provided with a ring at its end. Ordinary test tubes are fitted into the clips.



The advantages gained by this device are as follows. The hands do not touch the test tubes, and so remain dry for recording results. Burning and scalding accidents are prevented. Spurting when mixing is checked, the ejected fluid being received into the uppermost empty test tube. Thorough mixing is possible; the tubes may be shaken when horizontally opposed. The mechanism stands on the table like a tripod until the reaction occurs. The tubes are cleaned easily (together) under the tap, and can be used singly or together. The device hangs up when not in use.

The makers of this appliance are Messrs. S. Murray and Co., Ltd., 11–13, Farringdon Road, E.C.1.

PERCAIN.

Percain is a new local anaesthetic prepared by the Society of Chemical Industry in Basle (Messrs. Ciba). During the past year this substance has attracted considerable attention in Germany and Switzerland, and has been the subject of a number of articles in the medical press in these countries.

In the first place, percain is a local anaesthetic of a new type, for it is a quinoline derivative, related in its chemical structure to such drugs as quinine, atophan, and yatren, but totally unlike cocaine or novocain. Its chemical name is diethyl-ethylene diamide of α-butyl oxycinchoninic acid. All reports agree that its potency as a local anaesthetic is remarkable, and that it is many times stronger than cocaine. It acts both on nerve endings and on nerve trunks. It acts more rapidly, and has a more prolonged action than cocaine. It does not produce marked vaso-constriction, and therefore should be used with adrenaline.

It is recommended for use as an injection in a strength of 1 in 1,000 saline, and is also recommended in a 1 per cent. solution for surface anaesthesia of the nose and throat. Solutions can be sterilized by heat, but they must be protected carefully from alkali, and glass free from alkali must be used.

Percain is considerably more toxic than cocaine. Uhlmann (*Narcose und Anaesthesie*, 6, 168, 1929) found that in rabbits the minimal lethal dose of percain was one-fifth that of cocaine and one-fortieth that of novocain. Messrs. Ciba recommend that the maximum quantity injected should be 0.1 gram in 0.2 per cent. solution, and 0.2 gram in a 0.005 per cent. solution. Christ (*Narcose und Anaesthesie*, 6, June 15th, 1929) and Hofer (*Klin. Woch.*, July 2nd, 1929) report the use of the drug in several hundreds of operations in quantities up to 0.12 gram, and these authors state either that no toxic symptoms were observed or that the toxic symptoms were never serious or alarming. On the other hand, Freund (*Klin. Woch.*, 8, 1441, 1929) has reported a fatality following the injection of 0.13 gram percain.

HEALTH OF THE SCHOOL CHILD.

THE CHIEF MEDICAL OFFICER'S REPORT FOR 1928.

In his annual report on the School Medical Service, Sir George Newman, Chief Medical Officer of the Board of Education,* insists that the foundation of the medical care and supervision of school children is their systematic inspection. The purpose of such inspection is not only to detect those children who are sick or defective, but to obtain a physical survey of every child, and of school children as a whole. It is necessary, therefore, that every child, sick or well, should periodically come into the hands of the school doctor. In England it has been provided that routine medical inspection shall take place three times during the child's school life (5 to 14 years)—at entrance, at or about 8 years of age, and before leaving school. It is carried out as part of the school discipline; an approved schedule of the points of examination is adopted; the school nurse and teacher are present, and the parent is invited. In addition to the routine inspection, many children are referred for medical examination as "specials" by parents, teachers, or nurses, and there are many reinspections.

The school medical service has materially affected the direction of the wider movement of the national health, for, in a sense, the health of the infant and the child has become the primary factor of the national health. The child, writes Sir George Newman, has become the starting point of the new preventive medicine.

Scope of the Service.

The arrangements for carrying out routine medical inspection in this country may now be regarded as reasonably complete. During 1928 1,912,747 children, or 38.4 per cent. of those in average attendance (4,981,101), in the elementary schools were medically examined, an increase of 88,672 on the preceding year. The total number of children subjected to medical inspection was thus 2,849,132, being 57.2 per cent. of the number in average attendance.

The Nursing Service.

During 1928 the number of inspections as regards cleanliness carried out by the school nurses exceeded the enormous figure of 14 million; the percentage of individual children found unclean was 5.1, as compared with 5.6 of the previous year, and 6.5 in 1926. There was considerable variation in different parts of the country, and in some it reached as high as 18 per cent. As a minimum it is suggested that there should be a survey of all children in the schools as early as possible in each new term. Children who are in a condition with which they are likely to infest others should be excluded by the school nurses on their own responsibility or after reference to the school doctor, and cleansing should be arranged for.

In the work of "following up" there are advantages in combining school medical and public health nursing staffs. It precludes overlapping in visiting the homes, it places the nurse in a position of adviser to the family in matters of general and personal hygiene, and it secures more continuity in the supervision of the children from birth until the school-leaving age.

Medical Inspection and Treatment.

The proportion of children found to be suffering from definite defects varies little year by year. Excluding those with dental disease, the proportion referred for treatment and observation in 1925 was 23.8; in 1926, 20.1; in 1927, 20.6; and in 1928, 20.7. Defects of vision head the list in routine inspections, followed closely by defects of throat and nose; but in special inspections skin diseases far outnumber any of the other findings. Malnutrition was as low as 6 per 1,000 in 1924; it rose to 9.5 in 1925, and has remained at about this figure since. The recorded incidence of defects of vision and of the throat has increased, but this is judged to be due to better arrangements for inspection and the extended provision for treatment. There is evidence that the incidence of more severe disease causing exclusion from school is decreasing. The principal "school diseases" are shown to be defects of eyes, 10 per cent.; of the ear, nose, and throat, 7.9 per cent.; and skin diseases, malnutrition, and deformities. Besides these, there are children affected by minor ailments, dental disease, fevers, and the children who are gravely defective—the blind, deaf, and mentally deficient. Some of these children can be dealt with by the private practitioner (and to him reference should first be made); some by the school nurse; some need institutional treatment; some can be dealt with most satisfactorily at the school clinic. The number of defects (minor ailments, defective vision, enlarged tonsils, etc.) dealt with last year amounted to 1,167,809, and over a million children received dental treatment.

With one exception every local education authority has now made provision for eye treatment. After reviewing the various methods employed, the report concludes that there is much to be said for the method by which the school medical officer examines and prescribes for the bulk of the cases of errors of refraction, providing he has had the necessary experience in such work. The school medical officer is necessarily in closer touch with the children than can be a specialist who visits the area only occasionally. He is in a position to follow them up, see that they get appropriate treatment, and, if spectacles are prescribed, that they are obtained and worn. The treatment of squint engages the attention of an increasing number of authorities, of which 37 make arrangement for its operative treatment. The treatment of this condition should, it is suggested, be undertaken early by co-operation between the maternity and child welfare and school medical services.

During the year facilities for the operative treatment of enlarged tonsils and adenoids were provided by 267 authorities, but there are still 50 authorities which have not yet made such arrangements. The Board has indicated that a scheme for treatment of this defect cannot be regarded as satisfactory unless the operation is performed under proper hospital conditions by a competent specialist in ear, nose, and throat surgery, and unless post-operative retention of the patient for at least one night can be arranged.

Educational retardation is a fairly common result of adenoids, especially in the higher age groups. Its cause in a certain number of cases is the defective hearing which so often accompanies this condition; in others, there is a certain mental lethargy, which may be due to some interference with the cerebral circulation. Whether intelligence, as measured by the usual tests, is actually lower than normal does not seem to have been determined. This is a point worth investigating, particularly by a series of tests to ascertain whether any improvement in the intelligence quotient results from the removal of the adenoids.

New schemes for the treatment of orthopaedic cases were approved in twenty-three areas, bringing the total number of areas making such provision up to 183. The number of out-patient clinics maintained by local education authorities is 191, an increase of 41 over 1927. In addition, there are thirty-two areas in which treatment is obtained through voluntary agencies. There are 48 hospital schools having 3,876 beds (apart from sanatoriums, cripple and residential and open-air schools), but lack of special hospital accommodation prevents the full development of orthopaedic work in many areas. To meet this difficulty certain authorities send their "short stay" cases to local general hospitals, which are not in any sense "hospital schools." Such an arrangement has advantages, as it relieves pressure on the hospital schools, and by maintaining the local interest secures a continuity in the treatment at the hospital and the after-care; but it should be made only for cases which are not likely to need more than six weeks' in-patient treatment, and only when there is an orthopaedic specialist staff of surgeons and nurses at the local hospital.

The number of local education authorities which provided treatment by artificial light during 1928 was 64, an increase of 20 over the previous year. Treatment was given at 45 school clinics and 22 hospitals. The most frequently expressed opinion in school medical officers' reports is that ultra-violet radiation has most therapeutic

*The Health of the School Child. Annual Report of the Chief Medical Officer of the Board of Education for the year 1928. London: H.M. Stationery Office. 1929. 3p. 172. Price 1s. net.

value in those clinical conditions of subnormality not rigidly defined, but grouped under the term "debility." The treatment is in the nature of an accessory tonic, and the improvement which results from it is due to its general tonic effects rather than to any specific action. The evidence in favour of the treatment of various specific diseases is much more conflicting. Some medical officers admit frankly that the result of applying it to definite disease is disappointment, others prefer to withhold any categorical statement pending further experience and observations. The position of ultra-violet therapy in school clinics is summed up by Dr. J. P. Latt of St. Annes-on-Sea, who, in his report for 1928, says that "there seems little doubt that in artificial sunlight we have a valuable asset. It is certainly not, as claimed in some quarters, a panacea for all ailments, but in the majority of our selected cases it appears to have conferred considerable benefit, although time alone will show whether the improvement is of a temporary or permanent character."

Open-air Schools.

The number of day open-air schools for the education of delicate children suffering from non-infectious conditions is 62, providing accommodation for 6,556. There are, in addition, 14 provided, and 24 voluntary residential open-air schools, with a total of 2,409 places. The mere establishment of open-air schools for debilitated children is but a part of a full and proper recognition of the value of the open-air method in preventive medicine. What is needed, suggests the Chief Medical Officer, is the general provision of open-air and sunlight in all schools. Every school should in practice be an open-air school. At the present time 80 per cent. of the plans submitted to the board for approval include proposals for throwing open to the outside air whole portions of the classrooms. There has also been a wide adoption in both elementary and secondary schools of the open-air class in the playground, of the school journey, and of the school camp. This sort of progress exerts a greater effect in the long run than the building of special open-air schools for sick or defective children, important and indeed essential though that may be.

In almost every report on the work of special open-air schools during 1928, emphasis is laid on the improvement in general health of children after a comparatively short period of attendance, and on the large proportion of cases cured amongst those discharged. It is still too early to speak with any authority on the permanency of the cures effected, but the known facts justify the belief that this sort of school serves not merely as an institution for patching up weaklings, but as a definite unit in educational and health schemes providing for exceptional children.

Exceptional Children.

The total number of educable mentally defective children is returned as 22,626, which remains approximately the same as it was last year. The provision for this type of child has undergone little change; there are 21 residential schools giving 1,917 places, and 159 day special schools with accommodation for 15,091 children. Excellent work continues to be carried out in many areas by voluntary associations for mental welfare, which not only conduct occupation centres intended primarily for cases under the mental deficiency committee, but also visit the homes of children who are referred to them by school medical officers, and exercise supervision over these children, particularly during such period as may elapse before they can be admitted to special schools.

The number of school children reported to be blind and partially blind for the year 1928 was 1,887 and 5,225 respectively. The first figure shows a decrease of 38 over that of the previous year, the second an increase of 266. This increase—and the same applies to figures for the partially deaf—does not necessarily mean a higher incidence of the defect, but is the result of more complete ascertainment, stimulated in large measure by the increased provision which has been made for children suffering from partial disabilities. An analysis of the cases of deafness seen at the County Hall in the ten years 1919 to 1928 inclusive is quoted from the London report. It was found that the congenital cases amounted to 26.56 per cent., a much lower proportion than was found by investigators of half a century ago, who had to rely on less thorough and efficient methods of investigation. Of the cases of congenital deafness, 20.54 per cent. were of true "hereditary deafness" and 75.49 per cent. were of "sporadic deaf birth." A certain number of cases of the latter were due to syphilis, but during the last two years the conviction has grown that intestinal intoxication, which has been noted in an appreciable number of deaf children, plays a definite and important part in the product of deafness. The issue is further confused by the fact that the Wassermann reaction has been positive in some cases of chronic intestinal intoxication from which all possibility of syphilis could be excluded.

The number of children ascertained to be suffering from epilepsy so severe as to render them unfit to attend the public elementary schools is 2,521, a figure which has shown little variation over the past few years. Institutional accommodation for such cases remains about one-fifth of that required.

General Hygienic Measures in Schools.

The Board has had under careful consideration the question of the desirability of admitting direct sunlight in school-rooms, about which considerable divergencies of opinion exist. It is agreed that direct sunlight should not impinge on the desk, forehead, eyes, and back of the neck of children during work, and that cross shadows should be avoided. It is suggested, however, that too much stress has been laid on the danger of interference with work, and the detriment to eyesight, which may result.

As regards school buildings there still remain in many areas grave defects in the structure and sanitation of the schools, and in some a deplorable lack of the common necessities of decency and cleanliness—for example, defective sanitary conveniences, insufficient lavatory accommodation and equipment, and inadequate water supply.

Physical Education.

There are still 217 authorities who have left the physical culture of the children in their charge unorganized and undeveloped, though, to quote from the report, "physical culture in its broadest sense is far and away more valuable to the children of the nation than a thousand school clinics and an army of doctors and nurses. It may not be true to say that we must have the latter because we choose not to have the former, but it is indisputably established that if the authorities would follow the principle of preventive medicine there would be much less need to deplore the present great mass of disease and impairment which hampers the true education of the rising generation.

The Pre-school Child.

The problem of the pre-school child is still unsolved. There are nursery schools, but their increase is slow, for they are costly. This is due partly to their smallness in size; limitation of numbers was originally recommended with the idea of ensuring individual treatment and minimizing the danger of the spread of infectious disease. Experience has shown that under careful supervision the risk of infectious disease is less than had been anticipated, particularly where the school is conducted on open-air lines. The Board has intimated that, subject to its being satisfied about the accommodation and equipment, the provision of open-air facilities and the general conditions of supervision, it is now prepared to consider proposals for larger nursery schools, providing accommodation up to, say, 150 to 200 children. At the majority of nursery schools clubs for mothers have been formed, which are readily attended and where mothers receive advice in the care of their children. It is generally found that as the result of co-operation between parents, teachers, and nurses the standard of cleanliness and clothing is better, and that the school tends to raise the hygienic standards of the homes. Parental responsibility, it is believed, is increased rather than diminished by these measures.

BRITISH INSTITUTE OF RADIOLOGY.

ANNUAL CONGRESS IN LONDON.

THE annual meeting and exhibition of the British Institute of Radiology (incorporated with the Röntgen Society) was held at the Central Hall, Westminster, and at the Institute's headquarters in Welbeck Street, from December 4th to 6th, under the presidency of Mr. C. THURSTAN HOLLAND of Liverpool. One session was devoted to the discussion of radiation therapy, and another to papers dealing with physics and engineering questions; there was an informal discussion on what clinicians expect from the radiographer. Two memorial lectures were delivered: one, the Mackenzie Davidson Lecture, by Professor Gösta Forssell, the distinguished radiologist of Sweden, who spoke on the experiences of the "Radiumhemmet," or "radium home," at Stockholm; and the other, the Sylvanus Thompson Lecture, by Professor A. S. Eddington, F.R.S., whose subject was celestial radiation. Twenty-four firms contributed to an exhibition of radiological apparatus and material; a general impression induced by the exhibition was that screening stands and couches constantly become more massive and elaborate.

Mr. ARTHUR GREENWOOD, Minister of Health, who opened the congress, remarked on the team or co-operative spirit evidenced in every department of science, but nowhere more noticeably than in radiology, where medical men, physicists, and engineers were working to the same end, and, in the Institute, under the same auspices. One thing specially pleasing, he said, was the advance in protective measures, so that those now working in this field were no longer liable to the grave injuries and mutilations suffered by the pioneers. "While it is true," added Mr. Greenwood, "that the discovery of *x* rays was made in another country, it is a source of gratification that in England the first *x*-ray society (the old Röntgen Society) was formed, and the first journal published. . . . The manufacture of *x*-ray apparatus is not as large in this country as it is in the United States, or even in Germany, but for honesty of craftsmanship, soundness of work, and attention to the special needs of the user of the apparatus, the British manufacturers remain unexcelled the world over. . . . I have come here to-day, just as a humble man in the street, to congratulate the radiologists of this country on the work they have done, to exhort them to greater endeavour, and to express my hope for further advances in this important branch of knowledge and art."

Aspects of Radiation Therapy.

The principal medical discussion of the congress dealt chiefly with the value of radium treatment. Dr. N. S. FINZI, describing radiation therapy in malignant disease, said that it was more than twenty years since he began to use radium, having been impressed by what Dominici was doing at that time in Paris. During those twenty years radium had alternated in favour with *x* rays, but the truth was that each agent had its own sphere in relation to different cases, and in some instances the combined use of both agents was required. It was incumbent upon the radiologist to have a full knowledge of both. While radical *x*-ray treatment had been rather looked upon with disfavour in this country, when the results of St. Bartholomew's radiotherapeutic research department were published, those who held that view were likely to receive a shock. At the present time there was a boom in radium treatment, a matter of sorrow to radiologists, because booms were followed by slumps, and it took a long time for the pendulum to revert to a more normal movement. On the question of the radium "bomb," he said that this had many of the advantages of *x*-ray treatment in dealing with large areas, but the rays were more penetrating, and therefore more effective physically, and, he believed, biologically. From the point of view of physics, of course, the "bomb" was very inefficient; it would treat only three patients during the time that the same amount of radium, used in needle form, would treat a hundred. In deciding as between radium and *x* rays, Dr. Finzi was of opinion that in the case of very radiosensitive growths, such as lymphosarcoma and other rapidly growing tumours, *x* rays constituted the treatment of choice. In very small growths of a type which tended to remain localized, radium was indicated every time; the classical example was rodent ulcer. The position of the neoplasm was important. In growths in the region of the mouth and upper air passages the best results had been obtained either with *x* rays alone or with a combination of *x* rays and radium. Turning to tumours of the cervix, the speaker said that the combined method, radium for the local growth and *x* rays for the gland area, gave very good results; with *x* rays alone a tendency to recurrence had been observed at the site of the primary lesion. In rectal carcinoma radium seemed to be definitely more effective than *x* rays. In breast cases, if the mediastinum was involved, radium needle treatment was useless, but the case could still be treated by *x* rays. He had had two patients with carcinoma of the breast in which mediastinal metastasis had been treated by intensive methods lasting for two or three weeks; both were now well after five years. His final conclusion was that in operable growths in a number of situations radium treatment had now ousted surgery.

Radiological Treatment of Breast Carcinoma.

Mr. GEOFFREY KEYNES spoke of the difficulty of obtaining any true comparison between the results in carcinoma of the breast obtained by surgery and those obtained by radiological methods. Hitherto radiology had been reserved for special classes of patients, such as those who refused operation, those who were ordered prophylactic treatment after operation, those treated for recurrences, and the hopelessly inoperable. About eight years ago he began treating by radium those who had recurrences after operation; it soon became apparent that by the implantation of a small dose of radium for a considerable time the local recurrence could be made to disappear completely. After this result it seemed logical to suppose that equal success would be obtained locally in an unoperated carcinoma; therefore he began to treat primary carcinoma which were regarded by the surgeons as inoperable. Since that time he had gone on steadily increasing the number treated by radium alone. Up to the present he had a series of 145 cases at St. Bartholomew's in which radium had been employed in primary carcinoma of the breast. At the end of 1928, 67 patients had been so treated, followed up, and recorded; a good result had been obtained in 45 out of the 67, and about half of these had been described as "apparently cured" for periods extending to two and a half years. Of the 67 patients treated, 26 were inoperable, and a good result had been obtained in 12 out of the 26, half of whom had been—to use the cautious phrase—apparently cured. Mr. Keynes added that he was sure there was a field for *x* rays in supplementing the effects of radium.

Radium in Gynaecological Conditions.

Mr. MALCOLM DONALDSON described the use of radium in gynaecological cases at St. Bartholomew's. The technique had been to use in a gynaecological case a total amount of radium element of about 50 mg., split up into from twenty to twenty-five needles inserted around the growth and into the base of the broad ligaments, and left in position for 144 hours. The needle technique left nothing to be desired so far as local growth in the cervix or vagina was concerned; for deeper parts he was seriously considering adopting the Stockholm technique, but with some additions. He described in detail his intra-abdominal technique, and gave a detailed analysis of the St. Bartholomew's figures compared with the figures of the Medical Women's Federation, and those of the Brussels and the Paris workers. Turning to other malignant conditions, he spoke of carcinoma of the vulva. When this work was started at St. Bartholomew's Hospital five or six years previously large intensities were applied for twenty-four

hours, and very poor results were obtained. The application now consisted of very small intensities for a fortnight or three weeks, and the primary results were astonishing. He described one case of carcinoma of the vulva in which sixteen needles, each containing 0.3 mg., had been left in for a fortnight; he had seen the completely recovered patient recently, and there was not even a trace of any scar. Non-malignant conditions represented a much simpler problem; whether treating haemorrhage due to an abnormal menopause or to fibroids, the effect was the same, that of "knocking out" the ovaries. The only problem that arose, therefore, was as to what patients should be treated in this way, and very special consideration was necessary before deciding to treat patients under the age of 40; it must be remembered that the menopausal symptoms induced were likely to be very much more severe than in older patients. His experience of patients under 40 was small, but he did not think it would be possible to deal with them by modifying the dose of radium. He had attempted to give very small doses, with the result that there was amenorrhoea, but very severe menopausal symptoms ensued. He thought that if a larger dose was given in such cases the menopausal symptoms might be less; in other words, if the ovary was dealt with more severely there might be fewer symptoms than if it was only partly destroyed.

Radium and X Rays in Malignant Disease.

Dr. J. E. A. LANHAM said that almost every new recruit to the army of radium workers passed through a phase of enthusiastic optimism when he found that as a result of predetermined treatment a series of tumours could be made to disappear. He himself had been no exception to this rule, but as the years went on, and cases which had shown apparent cure came back with an extension of the disease, the following conclusions were forced upon him: (1) that lasting successes occurred only where the disease was localized; (2) that in certain cases isolated secondary growths appeared, but frequently responded to further irradiation; (3) that where the disease had become generalized not even local improvement could be produced; (4) that when recurrences developed in cases which had done well previously but now failed to respond, their appearance at the surface was frequently accompanied by extension of the disease elsewhere; in other words, the disease, which had been latent for a time, had suddenly become active. It appeared to him to be wrong to consider that there was nothing more to be done when a tumour had undergone retrogression after, say, the surgical use of radium. Such cases should be followed up by periodical *x*-ray treatment, or, if preferred, by external radium applications, not only to the site of the original growth, but to the related areas of lymphatic drainage and glands. With the obtaining of higher voltages the *x*-ray spectrum began to overlap that of the gamma rays. Apparatus capable of reaching far higher voltages than those yet used in *x*-ray therapy had been produced, and he had little doubt that sooner or later means would be found of giving *x* rays of correspondingly shorter length. Thus, as a matter of physics as well as of clinical experience, *x* rays and radium would tend to approach nearer rather than to diverge as time went on, and by combining them or alternating them in suitable cases more would be accomplished than if either method were used alone.

Use and Abuse of Radium Needles.

As a pendant to this discussion, Professor F. L. HORWOOD of St. Bartholomew's radium department, with Miss F. E. SMALLMAN, gave an interesting account of the care of the radium containers—230 of them, chiefly needles, containing approximately 500 mg. of radium element. These had been used in the treatment of 800 cases during two years, and usually about 50 or 60 per cent. of the needles were in employment. This efficiency figure was reduced, of course, by the fact that many of the patients treated were out-patients, and therefore only in attendance for short periods, and by the fact that some of the applicators were of a special kind involving a restricted use. Speaking broadly, needles of 1 and 2 mg. content in radium element had been found to be the types best adapted to the purposes of a general hospital. A very large number of needles—50 per cent. or more—were damaged during the year, though most of the damages were trivial. Long needles were much more vulnerable than shorter ones, and needles used for surface application were less liable to damage than those inserted into deep malignant growths. The policy of classifying a needle as "damaged" for every trivial injury, and setting it aside for immediate repair, had been thoroughly justified by results. Leakage of emanation from damaged needles was a comparatively rare occurrence if the needles had been gold-soldered. The intensive use of radium was likely to be accompanied by the temporary or permanent loss of some containers. When a loss was suspected it was advisable immediately to stop the dispatch of refuse or laundry articles from all departments of the hospital, and to institute a visual and electroscopic search. Containers which had accidentally passed through an incinerator might have lost all their emanation owing to the melting of the solder used as a seal; no reliance, therefore, should be placed on negative findings by an electroscope in such case. During nearly ten years the radium department at St. Bartholomew's had sustained a permanent loss of four needles, with a total content of 4 mg. One needle was known to have been buried with a patient, and three were untraced.

Radiotherapy of Malignant Tumours: Swedish Experience.

The tenth Mackenzie Davidson Memorial Lecture, delivered by Professor GÖSTA FORSSELL of Stockholm, embodied a description of the results obtained at the "Radiumhemmet" since its foundation in 1910. The Swedish Minister in London, Baron Palmstierna, was present. Dealing with the scope of radiotherapy in the treatment of cancer, Professor Forssell said that in about 20 per cent. of all cases of cancer in men, and in approximately 55 per cent. in women, radiotherapy, with or without combination with surgery, was the treatment of choice. To what extent primary healing (five-year cure) could be attained by radiotherapy for all localizations of cancer it was difficult to say, but on the basis of experience at the "Radiumhemmet" it was not too audacious to claim that in 15 to 20 per cent. of the entire number of cancer patients in Sweden primary healing could be effected by radiotherapy. Professor Forssell went on to inquire why radiotherapy, especially radium therapy, had not produced generally better results; the chief cause was the splitting up of radiotherapy. Radium had been distributed in various places without proper control, and the treatment and following up of results had also not infrequently been shared by many hands. Surgical intervention had been looked upon as of main importance, and radiation treatment as a more or less negligible adjunct. In reality the contrary was the case in most of the tumours in which radiotherapy could be used at all.

Experience in Sweden had indicated that radiotherapy for cancer could only attain full efficiency under particular conditions; specially equipped clinics were essential for improving and developing this method of treatment. They must be administered by qualified medical officers who had undergone a long training in radiotherapy, and specially trained nurses and technical assistants were also necessary. A radio-physical section under the supervision of a physicist, and a pathological laboratory under a tumour pathologist, were very important adjuncts. There must be organized co-operation between the surgical clinic and its special departments on the one hand and the radio-therapeutic clinic on the other. It was best that radical operations and such auxiliary intervention as called for much surgical skill should be performed solely at the surgical clinic, while minor operations might be undertaken at the radio-therapeutic clinic. In Sweden, with the aid of King Gustaf's Jubilee Fund, radiotherapy would be centralized at three clinics, which would be equipped as perfectly and completely as possible. One, for north and mid-Sweden, would be established at Stockholm; one, for south Sweden, at Lund, and, for west Sweden, at Gothenburg. The institutions in Stockholm and Lund would be connected with the university hospitals; the cost of treatment would be met in part by patients' fees and in part by grants from the State and municipality.

With regard to the future of radiotherapy in the treatment of malignant tumours, the directions in which there

were prospects of further progress and an increase in the percentage of cures over and above the results achieved by surgery were chiefly the treatment of such tumours as were restricted to the primary locality or the first glandular region in which surgical removal was rendered difficult by their localization or infiltration. In other words, the immediate sphere of development was in the so-called borderline cases. There was a vast field for the further development of radiotherapy in the combined surgical-radiological technique, where the task of radiotherapy would be, by irradiation prior to operation, to reduce the size of the tumour, to delimit it from its surroundings, and to minimize the risk of local re-implantation or spread. After operation it could be used to sterilize the adjacent glandular region.

The Clinician and the Radiologist.

At a meeting of medical members attending the congress, Dr. G. B. BATTEN opened a discussion on "The requirements of clinicians from radiologists, and vice versa." His argument was that clinicians might properly require from the medical radiologist what they would expect from other qualified specialists, and that they would expect from other should be given, as would any other specialist, a careful excerpt of the clinical data, and usually an indication of the clinician's opinion, which would help him to elucidate the problem he had been set. The important thing was that the clinician should take the radiologist into his confidence, and state in which directions radiological help was needed. On the delicate matter of answering a referred patient's anxious questions as to his case, Dr. Batten pointed out that very often the radiologist would have the perfect answer that he could not develop the film until later, but there were occasions, in barium meal examinations, for example, where the patient knew that the earlier films had been developed, and here the radiologist needed great wisdom and reticence if he was to preserve a proper professional attitude without unduly exciting the patient's fears. This difficulty was increased by the idea on the part of the public that *x* rays revealed anything and everything. Dr. Batten, after premising that there were very many clinicians who acted towards the radiologist with perfect understanding, classified others in the following categories: (1) those who regarded radiology as a joke not worthy of their consideration; (2) those who, while recognizing the advantages afforded by radiology, looked upon it as an unimportant part of their investigations; (3) those who, while valuing radiology, belittled radiologists and imagined that they were doing well to withhold any knowledge of the case from them; (4) those who wanted a radiograph taken, but desired to interpret it themselves, treating the radiologist as a mere photographer; (5) others, more ignorant, who expected a non-medical photographer to report on *x*-ray photographs, when he knew nothing of anatomy or pathology; (6) those who desired the radiologist to interpret the films as pictures only, without expressing any opinion about the condition giving rise to the appearance; (7) clinicians who left too much to the radiologist, sending immediately to the *x*-ray department a fracture or a doubtful chest without first trying to learn anything about it themselves.

An interesting but very informal discussion followed. Dr. STANLEY MELVILLE commented on the extraordinary change for the better which had taken place in recent years in the relations between the clinicians and the radiologists. If the radiologist did good work, and at the same time refrained from dogmatism in the absence of absolute certainty, his reputation among clinicians was secure. Dr. GRACE BATTEY, as a young radiologist, spoke with mingled amusement and complaint of some of the requests which reached the *x*-ray department. An insurance practitioner would send a rude scrawl on an envelope, "Ray this case." Another, more polite, but hardly more illuminating, would say, "Please *x*-ray progress of operation done three years ago." Another message would be, "*X* ray: query, abdominal." Dr. JOHN MUIR said that Miss Batten must learn to suffer fools gladly; insurance practitioners had no time to write flowery notes, and if they said "please," the radiologist should be duly grateful. In his own experience among salaried staffs of a Poor Law institution, hardly any of these troubles arose. Dr. D. D. MALPAS said that when asked by the referred patient to tell him the result of a bismuth meal examination, his reply was, "I have only got half your story. If I offered you a few pages torn out of a novel and asked your opinion on the plot you would have a right to complain."

After a number of speakers, including Dr. FRANCON ROBERTS, Dr. M. H. JEPP, and Dr. A. J. H. ILES, had related some of their experiences, the matter was summed up from the chair by Dr. L. A. ROWNTREE, who said that the whole question was one largely of give and take, but as soon as the radiologist began to disregard the clinical side of the cases he examined he very rapidly degenerated into a radiographer. One question raised in the discussion had been the ownership of the film. The film was the property of the radiologist who took it or ordered it to be taken. The patient had a right to know the interpretation, and it was not always easy to evade direct questions, but if one knew the colleague who had sent the patient it was generally possible for the radiologist to give satisfaction without doing his colleague an injustice.

Physics and Instrumentation.

In the session of the congress devoted to new apparatus, Mr. CUTHBERT ANDREWS exhibited a film, the work of Kodak Limited, showing the uses of a mobile *x*-ray unit introduced by X-Rays Limited. This unit was supposed to have been called to attend a case in the country where there was no electric supply, no dark-room facilities, no running water—"nothing but the patient." The film showed the setting up of the apparatus in the patient's room, and the production of a successful negative fifty minutes after the arrival of the unit at the house. Mr. W. E. SCHALL described a plant in which, by combining two distinct forms of electrical circuit within one unit, and arranging a switching gear from one to the other, it was possible to employ one and the same transformer to give diagnostic and therapeutic currents, both of them efficiently. Dr. E. J. H. ROTH exhibited an apparatus called the "mecapion" for the absolute measurement of the *x*-ray dose by ionization. In radio-therapeutic work a clock is set to the number of "*r*" units required, the ionization chamber adjusted carefully in relation to the patient, and, the *x*-ray apparatus and the "mecapion" being switched on, the latter automatically indicates the progress of the treatment, and rings a continuous alarm when the total dose has been reached.

Professor SIDNEY RUSS advanced some considerations about the relative factors of time and intensity in dosage, and repeated some of the remarks he made in the discussion on radium therapy recently at the Medical Society of London (*Journal*, November 2nd, p. 807). Dr. F. G. SPEAR and Miss S. F. COX read papers and gave demonstrations on tissue culture, the immediate and delayed effects of radium on tissues cultivated *in vitro*, and the action of *x* rays on living cells similarly cultivated.

Dr. FRANCON ROBERTS read to the congress a paper on modern radiological developments in Germany, with special reference to the new institute at the municipal hospital, the *Stadtisches Krankenhaus*, at Frankfort-on-Main, which he described as the most modern and best equipped institute in Europe. It consisted of three floors and a basement. The basement was given up to diathermy and ultra-violet light; the ground floor to *x*-ray diagnosis, with screening rooms arranged to permit 200 *x*-ray examinations a day; the first floor contained the high-tension apparatus, which was a great feature of the institute; and the top floor was devoted to radiotherapy, providing for 80 to 120 treatments a day. The building, which was under the direction of Professor Holfelder, had cost £28,000, exclusive of apparatus; the expense had been borne partly by the State and partly by the State Insurance Office of Germany. Dr. Roberts, on the basis of a visit to several towns in Germany, said his impression was that Germany was overwhelmingly superior to this country, both in the extent to which radiology was applied and also in the matter of equipment and organization. The liberality with which radiology was being endowed was part of the health policy of the German Government.

British Medical Journal.

SATURDAY, DECEMBER 14TH, 1929.

THE MENTAL TREATMENT BILL.

SPEAKING generally, the Government's Mental Treatment Bill, of which the text was printed in our *Supplement* last week (p. 247), is a notable advance on any previous lunacy legislation in this country, and its underlying purpose will be welcomed by the medical profession as a whole, and also, we believe, by local authorities and the public. The quiet but uninterrupted evolution of mental institutions from places of detention, "model lodging-houses for the insane," into well-equipped centres of scientifically directed curative effort, has brought about a great change in the popular attitude to mental hospitals and a new conception of mental disorder. Even if the word "asylum," now to be officially replaced by "mental hospital," is of somewhat sinister significance, there is to-day a widespread appreciation of the beneficent work of these institutions, and although it may still be necessary, even in the House of Lords, to remove misconceptions as to the nature of insanity and to elucidate the analogy between mental ailments and physical ailments, their usual coexistence and oft-times single cause, there is seldom any failure among the relations of those admitted to mental hospitals to recognize that mental disease is essentially a matter for medical study, medical diagnosis, and medical treatment, and the sooner the better.

Unfortunately, legal requirements have made it impossible to bring expert treatment within the reach of the great majority of the subjects of mental disorder at an early stage, when the chances of improvement and recovery are greatest. Formal certification, and especially insistence on the necessity of a magistrate's order—with all that these entail, even in cases when recovery is to be expected within a reasonably short time—have been and still are the main obstacles to early treatment. It will be remembered that the Royal Commission on Lunacy and Mental Disorder agreed unanimously that the treatment of mental disorder should approximate as nearly to the treatment of physical ailments as is consistent with the special safeguards which are indispensable where the liberty of the subject is infringed; that certification should be the last resort, and not a necessary preliminary to treatment; and that the facilities for treatment without certification should be developed, and voluntary boarders should be received into any public mental hospital, registered hospital, licensed house, general hospital, nursing home, or into single care. It should also be recalled that the Royal Commission took the view that for these purposes cases of mental disorder should be classified in two categories—namely, voluntary (that is, patients possessing volition and willing to be received into an institution as voluntary boarders), and involuntary (that is, all others). The latter group comprises the great majority of cases of mental disorder, including very many early and recoverable patients who are either devoid of volition or unable to give a reasoned assent, as well as those who, being in need of care, treatment, and protection, either in their own interests or those of others, refuse to acquiesce in, or deliberately object to, such care and treatment. For this non-volitional class, if recovery were to be anticipated under six months, the Royal Commission proposed a "provisional treatment order" requiring only one medical statement, but requiring also, "though not without some reluctance," the order of a magistrate. If the outlook were less promising the cases would have to be dealt with under a reception order requiring two medical certificates in addition to the order of the magistrate.

As our readers are aware, the British Medical Association, in the evidence it tendered to the Commission, *recognized not two, but three groups or categories* of patients—namely, volitional, non-volitional, and resistive—and while in general agreement with the Commission as to the provision recommended for the voluntary group, the Association strongly opposed magisterial intervention in the case of the non-volitional patient for the purposes of the provisional treatment order—or, as the Association desired it should be named, the authorization of treatment order. The Association, while anxious that the authorization of treatment should be made not by one but by two medical men, either singly or in conjunction, pressed on the notice of the Royal Commission that the intervention of a legal official at the outset of treatment continued the formalities of the existing law; that it did nothing to bring about the approximation of the treatment of mental illness and the treatment of bodily ills which the Commission desired; and by perpetuating—indeed emphasizing—the "stigma of certification" so deeply resented by the public, would cause the relatives of patients to postpone active measures as long as possible, and so defeat the very object of this provision. The Royal Commission, however, was not able to accept this view, even though it said, "If we were free to consider exclusively the medical treatment of the patient we should have little hesitation in accepting the suggestion," and also considered that "ultimately the treatment of mental illness will be so assimilated to the treatment of physical illness that the participation of a magistrate will no longer be considered necessary."

It is of extreme interest at this point to turn to Clause 5 of the Government's bill, which provides that "a person suffering from mental disorder and for the time being incapable of volition, but who is likely to benefit by temporary treatment, may be received as a temporary patient for the purpose of treatment into an institution provided by a local authority, or any other institution, hospital, or nursing home as may be approved by the Board of Control, or, with the consent of the Board of Control, into single care. The application for reception of a temporary patient, to be made by the patient's responsible relative, is to be accompanied by a "recommendation for temporary treatment" signed by two registered medical practitioners, one of whom shall be either the usual medical attendant of the person to whom the application relates, or a practitioner "who has been approved for the purpose of making recommendations under this section either by the Board of Control or by the local authority within whose area the said person then is." The doctors signing the recommendation may examine the patient either separately or in conjunction. Notice of the patient's reception and a copy of the application and form of recommendation are to be sent to the Board of Control, and provision is made for a visit being paid him within one month after his reception by at least two members of the visiting committee, or in a licensed house by two of the visitors, or in certain

cases by the Board of Control. The maximum period of treatment as a temporary patient is laid down as six months. There is no magistrate's order.

It is impossible to read this part of the Mental Treatment Bill in conjunction with the British Medical Association's "Memorandum on the Report of the Royal Commission" without coming to the conclusion that, while the framers of the bill have been guided by the principles enunciated in the Commissioners' Report, they have been gratifyingly attentive to the voice of the medical profession, and have given effect to many of the suggestions tendered to the Commission by the Association's representatives. The bill as a whole is in process of scrutiny by the Association's special Committee on Lunacy Law and Mental Disorder. Unquestionably it requires emendation or amplification here and there; but there can be no doubt that in the main this bill, if it becomes law, will at long last approximate the treatment of mental disorder to the treatment of physical ailments in the very cases in which this is likely to prove most efficacious. Great changes, administrative and other, would follow its enactment.

From the point of view of the medical profession one of the most important parts of the bill is Clause 16, which deals with the protection of persons performing duties under the Lunacy Acts. This clause provides that Section 330 of the principal Act shall be amended by substituting for it the following:

"(1) Where a person has presented a petition for a reception order, or signed or carried out, or done any act with a view to signing or carrying out, an order purporting to be a reception order, or any report or certificate purporting to be a report or certificate under this Act, or has done anything in pursuance of this Act, he shall not be liable to any civil or criminal proceedings, whether on the ground of want of jurisdiction or on any other ground, unless he has acted in bad faith or without reasonable care.

"(2) If any proceedings are taken against any person for presenting any such petition or for signing or carrying out, or doing any act with a view to signing or carrying out, any such order, report, or certificate, as mentioned in Subsection (1) of this section, or doing anything in pursuance of this Act, such proceedings shall, on application to the High Court, be stayed on such terms as to costs and otherwise as the court may think fit, unless the court is satisfied that there is substantial ground for alleging that such act was done in bad faith or without reasonable care."

Although clearly a step in the right direction, inasmuch as it shifts the onus of proof of mala fides from persons (including medical practitioners) whose conduct is impugned to the plaintiff, this does not give the full measure of protection claimed by the medical profession. Lord Sandhurst, however, has tabled an amendment to be moved in committee, which goes a very long way towards meeting the wishes of the British Medical Association. His amendment proposes that the latter part of Subsection (1) of Clause 16, quoted above, shall run as follows:

". . . he shall not be liable to any civil or criminal proceedings whether on the ground of want of *jurisdiction or on any* other ground unless he has acted in bad faith *or negligently and without reasonable and probable cause. Provided that in case of a trial with a jury, the question of reasonable or probable cause shall be determined by the judge.*"

And in the same way *Lord Sandhurst* proposes that the words "without reasonable care" at the end of Subsection (2) shall be left out, and the words "negligently and without reasonable and probable cause" substituted for them. The Association's special committee has thanked Lord Sandhurst for introducing this amendment of Clause 16, and has expressed the earnest hope that it will be approved by the House of Lords and included in the Act as passed.

THE CAUSE OF NATURAL ABORTION.

THE term "natural abortion" is generally used to cover all abortions except those which have been artificially induced, a distinction equivalent to that made in forensic medicine between "natural" death and death by violence. Just, however, as in a stricter sense the term "natural death" may be applied only to death resulting from the senile decay and atrophy of tissues, so also may the term "natural abortion" be limited to the kind that occurs when Nature discards certain embryos whose development it will not allow to proceed beyond the initial stages. In his paper, which appears at page 1095 of this issue, Professor Beckwith Whitehouse uses the term "natural abortion" in its wider sense, and in discussing its causes confines his attention for the most part to general maternal states and local conditions in the reproductive tract—for example, syphilis, diseases of the decidua, nutritional and other environmental conditions—which are detrimental to the development of the embryonic element. He draws attention, however, to the two factors—namely, an inherent defect in, or incompatibility of, the germ cells—which underlie the production of true natural abortion, though he does not appear to distinguish between them. There are, in fact, grounds for the view that in most cases the fault lies not in the germ cells themselves, but in the zygote formed by their union; in short, that an important cause of sterility and abortion may be found in a so-called incompatibility of the gametes.

Professor Arthur Robinson, in his Struthers Lecture of 1921, and more recently at a joint discussion of the Sections of Obstetrics and Gynaecology and of Comparative Medicine of the Royal Society of Medicine,[1] extended the definition of sterility to cover the incapacity of a pair to produce living young who should survive until the natural period for their own reproduction and be themselves fertile—a definition which logically includes true natural abortion within the concept of sterility. In order to discover what proportion of total matings were unproductive, whether on account of sterility or of abortion, he analysed the records of horse-breeding societies, and found that out of some thousands of ova shed, 48 per cent. in the case of Clydesdale mares, and 58 per cent. in that of thoroughbreds, did not produce young, although the matings had been carried out under controlled conditions and the stallions used were all in perfect health. These findings were consistent with the view commonly held by breeders that pure-bred stocks are less fertile than those which have been cross-bred. Professor Robinson's observations on ferrets, and similar observations by others on small *mammals*, including wild rabbits and moles, have tended to show that there is always some natural wastage of fertilized ova, in the uterine cornua of some mammals degenerate zygotes being found side by side with others developing normally. These degenerate zygotes are absorbed if their death follows shortly after fertilization. If, however, degeneration occurs late, the fate of the zygote depends on whether the mammal in whose uterus it is embedded produces a litter or only one foetus at a time. In the former, pregnancy proceeds to term, the degenerate zygotes being expelled with the normally developed foetuses; in the latter, natural abortion occurs, rendering possible immediate preparation for fresh gestation. The production of foetus papyraceus may be regarded as the nearest approach in human reproduction to the process which occurs in

[1] *British Medical Journal*, October 26th, 1929, p. 760.

the litter-producing mammals, though its cause may not be quite the same.

While, however, there is no evidence that the production of degenerate zygotes is due to an inherent defect in the ova and sperms, other combinations in the same animal being capable, indeed, of normal development, there exists some experimental justification for the other view—that their production may result from the union of incompatible gametes. Thus in the course of breeding fancy coloured mice, in which yellow is dominant to any other colour, it was found that the matings of hybrid yellow mice failed to give rise to the proportion of yellows to non-yellows expected by Mendelian law, the anomaly being due to the fact that in these matings there was a much higher incidence of dead embryos than in the matings of yellow with non-yellow. As, furthermore, no pure yellows were produced, it seems as though the combination of yellow-carrying sperm and yellow-carrying ovum was incapable of developing, whereas zygotes formed by the union of yellow-carrying with non-yellow-carrying gametes could survive. These results in mice, which have been confirmed in other biological types, give a new meaning to the vague term "incompatibility" that has been applied to some cases of sterility and habitual abortion for which no better reason has been forthcoming. Nature, it would appear, abhors certain gametic combinations, and in her effort to produce variations in type has set a limit to pure breeding—a view that provides an explanation for the relative infertility of pure-bred animals. There can be little doubt that similar lethal nuclear combinations occur in the human subject, though no estimate can at present be made of how large a part they have in determining the incidence of sterility and abortion. The existence of such a lethal form was postulated by Dyke in his paper on the inheritance of blood groups.[1] The agglutinable properties of the corpuscles being dominant and the agglutinins in the serum recessive, Dyke considers that the gametes of blood group I (Moss), with the double dominant and no reciprocal recessive, might be incapable of fruitful union; and he puts forward this hypothesis in explanation of the rarity of blood group I. Other like hypotheses have been, and doubtless will be, suggested, and it is important in considering the causes of abortion and sterility to bear them in mind as well as the more obvious environmental conditions that might be responsible.

THE POET LAUREATE.

At the age of 85 Dr. Robert Bridges has given to the world the greatest English philosophic poem of modern times. He thus joins the select band of illustrious men—Clifford Allbutt amongst them—who have made of Time a laughing-stock, their faculties knowing not decay, the passage of years bringing only a ripened wisdom. Dr. Bridges has been accorded due and unaffected praise by the professional critics of his own craft; but for us his poem has a peculiarly fraternal appeal, and we must honour him in this place as one whose rare communion of gifts has enabled him to achieve the miraculous marriage of poetry and science. He calls his poem *The Testament of Beauty*,[2] and thus, by inevitable comparison, declares its lofty purpose. It does not fail. To those who know him only as a lyrist, albeit a player of delicate music perfectly instrumented, this poem will reveal his true measure, for here is thought symphonic in depth and in form of execution. The medical mind, in contact day by day and hour by hour with stark reality, is apt to be impatient with philosophers, and in particular to find philosophic poetry irksome reading. The character of Dr. Bridges's poem, however, is such that a general knowledge of science is requisite for its proper appreciation. His own learning is wide and deep, and is fearlessly used; and for the scientific reader there is no tiresomeness, only intense interest. The background of thought of the book is scientific, its framework a conception of Plato, its vision poetic. The poetry, indeed, is the lamp which illumines the philosophy. An eminent botanist was once asked if his knowledge of the structure of plants did not mar his sense of their beauty. He replied that his consciousness of the wondrous beauty of the botanical world grew out of his intimate knowledge, and was therefore a profounder sense than that of beauty only "skin deep." So Dr. Bridges. He sees beauty as a flowering of the human mind; but he knows the make-up of mind, its animal foundations, its struggles in development, the springing of its higher functions from the lower. This is what makes beauty a natural attribute of the mind, since its roots are in mind as Nature made it. The present age—and so far as can be seen the future will be like it—is the age of specialism, a condition imposed on humanity by the swift progress of knowledge and the general quickening of the manner of life, which make it impossible for one mind to secure sufficient time for much activity outside the sphere of its own work. It is fortunate that in such an age there are still men unfettered by the toil and moil, whose mental grasp can embrace widespread essentials, link them together, and interpret the whole so that any man of ordinary culture can read and understand. Dr. Bridges is of this company, and to listen to his measured authoritative voice and dip in his well of cool thought is refreshment to the mind and revival of faith to the soul. Such are the impressions created by a single reading of *The Testament of Beauty*. But the book will fully reveal itself only after many days.

TENNIS ELBOW.

THE discussion on minor injuries of the elbow-joint in the Section of Orthopaedics of the Royal Society of Medicine, a report of which appears on page 1109, was instructive if inconclusive. It centred round the injury or group of injuries known by the loose if convenient term of tennis elbow, although such a group of symptoms is not confined to tennis players, but sometimes troubles fencers and others who employ their upper extremities in rapid movement. It is true that other lesions, such as fissure of the head of the radius, were considered, but speaker after speaker seemed to feel that this rather elusive lesion—or perhaps it were better to say syndrome—occupied the most important place among the minor injuries of the joint. In a paper published last year[1] Mr. Percival Mills of Birmingham declared that while surgeons were discussing its pathology the trouble was being cured by osteopaths and non-medical manipulators in hundreds of cases. He went on to describe a method of manipulation under nitrous oxide anaesthesia by means of which the symptoms could be made to disappear at once and for all. Everyone, including Mr. Mills, is agreed that the symptoms of tennis elbow come on gradually, even insidiously; which fact makes it very difficult for the pathologist to accept the hypothesis that the symptoms are due to the nipping of some structure, such as the orbicular ligament, between the head of the radius and the humerus, even if the anatomical possibility of such an event be admitted. Mr. W. H. Ogilvie, who opened the discussion, did not confine himself to the subject of tennis elbow, but after giving a detailed description of the anatomy and

[1] The Treatment of Tennis Elbow, *British Medical Journal*, 1929, i, p. 12.

functions of the joint he described a number of other injuries. Incidentally we would thank him for laying (we hope permanently) the ghost of that old impostor, the "carrying angle" of this joint. The angle exists beyond a doubt, but it has nothing to do with facilitating the carrying of weights. No speaker seemed to be enthusiastically in favour of the method of sudden cure by manipulation under an anaesthetic, although some of them spoke of having had favourable results. Only one, Mr. Trethowan, related his experience of actual inspection of the affected joint on the operating table. It is significant that he found injected synovial fringes in all of the eight otherwise intractable cases of tennis elbow in which he explored the joint, but even after the removal of such fringes there is no dramatic suddenness about the cure, such as has been reported of some of the manipulated cases, in which a loud "report," as of a breaking bone, has been heard. One can hardly credit a synovial fringe with the production of such vibrations. The impression left on our mind by this discussion is that the etiology of tennis elbow is various, its pathology obscure, and its cure uncertain.

THE CENTENARY OF TORONTO UNIVERSITY.

On October 5th to 9th, 1927, the University of Toronto celebrated its centenary, and now a record[1] of the proceedings has been published in book form "by authority of the Board of Governors of the University." On March 15th, 1827, King George IV granted a charter for the founding of a University for the Province of Upper Canada, to be known as King's College, at Toronto. Instruction, however, did not begin in King's College until 1843, and it was seven years later before the College was reorganized as the University of Toronto. But the Royal Charter granted in 1827 was the basis on which the University has been built up, and may therefore properly be regarded as marking the beginning of its history. In an address delivered at the centenary, the president, Sir Robert Falconer, gave an account of the first century of the University, and showed that the credit for taking the first steps in 1798 towards the establishment of the University belongs to John Graves Simcoe, the first Lieutenant-Governor of Upper Canada, and that the Rev. Dr. John Strachan was mainly responsible for obtaining the Royal Charter. The original conditions were of an exclusive religious character, and confined the management and education to members of the Church of England. In a country in which most of the inhabitants did not belong to this denomination these restrictions naturally aroused so much controversy that, as already mentioned, teaching was delayed until 1843; in 1829 the Upper Canada College was started for the same reason, and university teaching was begun by Victoria College, at Cobourg and by Queen's College at Kingston in 1841 and 1842 respectively. The University passed through four well-marked stages—the progressive secularization of King's College until it took the name of the University of Toronto in 1850, isolation (1850–89), the consummation of federation (1889–1905), and unification and expansion (1905–27). In the last period the growing prestige of the University brought in private benefactions of more than six million dollars, which have provided beautiful buildings and made it possible to realize the ideals of federation. During the war (1914–18) the University underwent a consecration in her baptism of blood, for more than six thousand graduates and undergraduates were on active service. The greater part of the volume is occupied by addresses of congratulation from the delegates, the first being that of Professor Emile Sergent of the University of Paris, then that of the Hon. N. D. Baker, formerly United States Secretary for War, and then Sir Charles Sherrington on behalf of the delegates from Great Britain and the Dominions other than Canada. The very numerous addresses, letters, and telegrams from universities, colleges, and other learned institutions, some in Latin, others in their own tongue, are duly printed.

INTERNATIONAL LEAGUE FOR COMBATING RHEUMATISM.

An indication of the amount of work that is being done on the problems of rheumatism may be found in the long list printed in the October issue of *Acta Rheumatologica* (the official journal of the Ligue Internationale contre le Rhumatisme) of books, pamphlets, and articles about rheumatism which have been received by or brought to the notice of the league's bureau during the period April to August, 1929. The items include no fewer than 127 in English, 105 in German, and somewhat fewer in French, Spanish, Dutch, Italian, and the Scandinavian languages. The objects of the league, as outlined in its constitution and laws, are to establish a contact among the national committees or other organizations in the campaign against rheumatism in the various countries of the world; to coordinate the efforts of these committees; to promote relations with international organizations for health; to organize conferences, scientific and social; to make comparative studies of rheumatism, experimental, statistical, and clinical; to provide for the collection of relevant international statistics; to stimulate investigations in various countries and races; and to collect and distribute information on all matters concerning the study of rheumatism. The league, while aiming to act as a central official body in the international campaign against rheumatism, wishes in no way to limit the liberty and scope of national committees which have been established for the purpose of studying or combating rheumatism, but to encourage and assist in their formation. Through the medium of the *Archives of Medical Hydrology* and other publications it hopes to circulate information of general value, statistical and otherwise, and to make suggestions for a better classification and nomenclature of chronic rheumatic disorders and for desirable lines of investigation and research. The October issue of *Acta Rheumatologica* includes articles on the significance of serological and blood examinations in rheumatic disease; the relation between chronic and acute rheumatism; and the use of Abderhalden's reaction in the diagnosis of rheumatic diseases. Contributions in this issue come from Hungary, Austria, Germany, Holland, Sweden, and England. A journal of such an international character should play no small part in facilitating rapid exchange of information about the problems of rheumatism, and should prove of great help to those who are now engaged in their solution.

"CANCER: A DISEASE OF CICATRICES."

When, in the year 1922, the anti-cancer campaign was instituted in France, subcommittees were appointed to deal with the several aspects of the question. It was, however, considered that of the various problems calling for discussion that of prophylaxis should be excluded, on the ground that our knowledge of the nature and etiology of cancer was too scanty to promise any practical results. In order to dispel what he considers an erroneous view, Dr. A. Lumière has published a small volume[1] to show how much may be done by way of prophylaxis, even with our limited knowledge. He confines his observations to the subject of carcinomatous growths. These he regards as always arising

[1] *Le Cancer: Maladie des Cicatrices.* By Auguste Lumière. Paris: Masson et Cie. 1929. (18 fr.)

in a pre-existing cicatrix, and he adduces a formidable body of evidence in support of that opinion. He regards cancer, *in fact, as a disease of cicatrices.* He holds that a very prolonged period is required for the cicatrix to modify the tissue cells in the direction of malignancy, and, further, that a trauma of some kind—not necessarily a gross trauma—is necessary to start the proliferative process, arguing by analogy from the experimental proliferation of cells induced by mere punctures. Finally, humoral modifications are considered to be probably necessary to permit of the cell proliferation. Starting with this theory of the nature of cancer, the author argues that in not a few instances the prophylaxis of cancer is simply the prophylaxis of cicatrices. Such cases as *x*-ray and radium cancer and the kangri cancer of Kashmiri peasants are obvious instances; the prophylaxis here is incontestable—if the cicatrix is avoided there will be no cancer. A somewhat different class of cases is exemplified in the practice of Dr. Casalis de Pury among the Basutos. During a period of thirty years de Pury never met with a single case of cancer, but since the stream of civilization has flowed into the country, with its bacillary, specific, and alcoholic adjuncts, Basutoland is as prolific in cancer as any country in Europe. Here, the author contends, the prophylaxis of cancer is the prophylaxis of alcoholism, syphilis, and other infections, all of them cicatrix-producing diseases. A captious critic might here inquire why the cicatrices of the Basutos in the former period should be so free from malignant degeneration—a point which appears to have escaped investigation. With regard to the humoral aspect of the problem, such measures as the administration of chemical substances with a view to rendering the tissues an unsuitable soil for carcinomatous growths have not so far produced very striking results; but that is no reason, as the author justly remarks, for losing faith in the future.

THE RADCLIFFE INFIRMARY, OXFORD.

JOHN RADCLIFFE (1653–1714), the successful physician in London for thirty years, was a needy boy who gained an exhibition on the Freeston Foundation at University College, Oxford, and was subsequently a Fellow of Lincoln College. He generously repaid his Alma Mater by leaving the whole of his fortune (£140,000) to trustees for the advancement of the study of natural science and medicine in connexion with the University of Oxford, where his name is perpetuated in the library, observatory, and infirmary called after him. Many stories are told of him in *The Gold-Headed Cane;* the late Dr. J. B. Nias, a Radcliffe Travelling Fellow, dutifully wrote a sketch of his life, with an account of his Fellows and Foundations; and Dr. A. G. Gibson has supplemented this with *The History of the Radcliffe Infirmary.* Among the moderns who have followed Radcliffe's generous example Cecil Rhodes, born three centuries later, stands out as a Colossus for his endowment of the Rhodes scholars with the wealth he acquired in South Africa. Now, with the whirligig of time, the Radcliffe Observatory, which is the immediate neighbour of the Radcliffe Infirmary, is to be moved to a site on the high central plateau of South Africa, where the conditions for astronomical research are the best in the world. This will take place in about five years' time, when the observatory will have completed its researches into the movements of some 30,000 faint stars. But in the meantime the grounds of the observatory are being acquired, largely by the generosity of Sir William Morris, for £100,000 by the Radcliffe Infirmary, so that much-needed extensions, especially the erection of a maternity block, can be proceeded with at once. The Radcliffe Infirmary, built in the middle of the eighteenth century with funds provided by the Radcliffe Trustees on five acres given by Thomas Rowney, an Oxford citizen, will thus be enabled to become a hospital worthy of the University and its traditions, if it cannot become a University hospital, which is a different proposition. Widely as Radcliffe's name has been carried by his Travelling Fellows, one of his benefactions—the observatory—will find a permanent home in a far distant land, a result of which he never can have dreamed. Like his other benefactions, the library and the Travelling Fellowships, the observatory has moved with the times, and will for ever keep his memory green.

RECONSTRUCTION OF ST. BARTHOLOMEW'S HOSPITAL.

THE inauguration by the Prince of Wales on December 4th of a campaign to raise £1,000,000 for the reconstruction of St. Bartholomew's Hospital marks the opening of a new chapter in a long and famous historical record, which began when Rahere, in the spring of 1123, raised two buildings just outside the walls of the City of London, one to minister to the souls of men and the other to their bodies. When, after the passing of 250 years, the Convent of Augustinian Canons was separated from the Hospital of St. Bartholomew in consequence of long-continued bickering, a step was taken which saved the hospital, 150 years later, from sharing the fate of the convent when it was suppressed in the reign of Henry VIII. The Prince of Wales, who has followed his father, grandfather, and great-grandfather as president of the hospital, and, it may be recalled, took in 1923 a prominent part in the octocentenary celebrations of its founding, compared the present ideals of Bart. with those of ancient Greece, when physical fitness was conceived to be a supreme duty of citizenship, and even an object of worship. Yet it seemed, he remarked, that only now was the immense economic value of good health beginning to attract the consideration it deserved. Medical work was still being grievously hampered by imperfect conditions, and the progress of scientific research was retarded by financial restrictions. So he set in motion a flashing signal on the roof of the hospital to be an urgent reminder of the present need. The south, east, and west quadrangle blocks are all more than 150 years old and must be reconstructed within, though the familiar outward walls will remain. The maternity department and some of the other specialist departments are lamentably inadequate. The new surgical block is approaching completion, with its five new operating theatres, but more than £130,000 is still required to pay for this and the extension of the nurses' home. Other necessities are: the enlargement of the out-patients' modern block to provide departments for child out-patients, orthopaedics, and massage; wards for obstetrics and gynaecology, as well as for children who at present have to be accommodated among the adults; improved theatres and laboratories for the medical college; and endowments for professorial chairs and for an institute of research. It is proposed later on, when these urgent needs have been met, to erect a residential college for students in the neighbourhood of the hospital. A wide prospect of more extensive and more effective medical and scientific work is envisaged by this, the second great appeal by St. Bartholomew's Hospital since its foundation. The sum desired is large, but not too large to be obtained if all who have been connected with the hospital in any way, whether as governors, patients, students, or staff, use their influence with others, and contribute personally according to their means. So long an historic tradition should surely compel sympathy of a practical kind, particularly when it is realized that such support must be forthcoming if the hospital is to keep its position as a temple of health and healing, a great school of medicine, and a centre of scientific research, where Harvey's successors may find opportunities to widen the field of knowledge and to diminish the sum of human suffering.

Collective Investigation
INTO
THE AFTER-HISTORY OF GASTRO-ENTEROSTOMY.

Report by
ARTHUR P. LUFF, C.B.E., M.D., B.Sc., F.R.C.P.,
CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL; HONORARY DIRECTOR OF THE RESEARCH.

PART II.—PYLORIC ULCERS.

THERE were 454 reports of the results of operations for pyloric ulcers; they do not include the perforated cases, which are dealt with separately in Part III. The answers to the various questions have been carefully collated, and the results are embodied in the following tables.

TABLE I.—*Sex Incidence.*

Number of cases	454
Males (percentage)	72.4
Females (percentage)	27.6

This table shows that about three times as many cases occur among males as among females. With the duodenal ulcers the percentages were: males 83.6 and females 16.4.

TABLE II.—*Age Incidence (at Time of Operation).*

Age.	Percentage.
15-30 years	9.5
30-40 ,,	29.7
40-50 ,,	32.8
50-60 ,,	17.8
60-70 ,,	10.2

This table shows that the majority of patients with pyloric ulcers were operated on between 30 and 50 years of age, as also were those with duodenal ulcers. Of the patients operated on between 16 and 30 years, one patient only was 16 years of age.

TABLE III.—*Type of Operation.*

Type of Operation.	No. of Cases.	Percentage
Posterior gastro-enterostomy	352	77.5
Posterior gastro-enterostomy and embedding of ulcer	72	15.9
Anterior gastro-enterostomy	5	1.1
Partial gastrectomy and lateral anastomosis	7	
Partial gastrectomy and posterior gastro-enterostomy	5	
Posterior gastro-enterostomy and pylorectomy	3	
Posterior gastro-enterostomy and excision of ulcer	2	
Partial gastrectomy	2	
Posterior gastro-enterostomy and cauterization of ulcer	1	25 5.5
Posterior gastro-enterostomy and lateral anastomosis	1	
Anterior gastro-enterostomy and embedding of ulcer	1	
Ramm-tedt's operation	1	
Pylorectomy and Billroth II	1	
Posterior gastro-enterostomy, embedding of ulcer, and gastro-colopexy	1	

In addition appendicectomy was performed in 18 per cent. of the cases, and cholecystectomy in 0.9 per cent.

The reasons for operating were given in 446 cases. These are recorded in the following table.

TABLE IV.—*Reasons for Operating.*

Symptoms.	No. of Cases	Percentage
Pain	446	100.0
Vomiting	239	53.6
Haematemesis	39	8.7
Haematemesis and melaena	8	1.8
Melaena	8	1.8
Loss of weight	42	9.4

With regard to haemorrhage as one of the reasons for operating it will be seen from the above table that all the cases in which haematemesis and melaena occurred (separately or combined) only total 12.3 per cent., but amongst the 446 cases very few systematic investigations for occult blood are recorded. Haematemesis was slightly more frequent in the duodenal ulcer cases than in the pyloric, and melaena was much more frequent in the duodenal cases.

The following are the direct results of operation in the 454 cases.

TABLE V.—*Results of Operation.*

Result.	No. of Cases.	Percentage.
Good recovery	433	95.4
Delayed recovery	9	2.0
Deaths	12	2.6

The percentage of good recoveries is rather higher than in the case of duodenal ulcers, where it was 91.5 per cent. The post-operative mortality is considerably lower than the 5 per cent. post-operative mortality among duodenal ulcers.

Prior to operation 250 cases were submitted to *x*-ray examination, with the following results.

TABLE VI.—*Results of X-Ray Examinations.*

Result.	Percentage.
Positive	50.0
Negative	12.0
Pyloric obstruction only shown	38.0

The percentage of cases showing pyloric obstruction only is twice as great as in the case of duodenal ulcers.

In 77 cases test meals were employed prior to operation, with the following results.

TABLE VII.—*Results of Test Meals.*

Result.	Percentage.
Hyperchlorhydria	80.5
Normal acidity	17.0
No free hydrochloric acid	2.5

AFTER-HISTORIES OF THE OPERATION CASES.

The 454 cases dealt with in Tables I, II, III, and V include 320 cases in which the after-histories were given, 9 cases in which the after-histories consisted only of statements that the patients were in good health at some specified time after operation, and 125 cases in which no after-histories were given. For the preparation of the after-history statistics the 320 cases only are employed. As in the report on duodenal ulcers, the statistics in the following tables have been worked out as percentages of the numbers of the answers to the respective questions. The after-history inquiries were directed to the elucidation of the same points as in connexion with duodenal ulcers (see Part I, *British Medical Journal*, December 7th, p. 1075).

TABLE VIII.—*Pain or Other Discomfort after Food.*
(Information on these points was given in 299 cases.)

	No of Cases	Percentage.
No pain or discomfort	231	77.3
Occasional slight pain or discomfort	37	12.4
Temporary pain or discomfort (in most cases soon after operation)	23	7.7
Severe pain or discomfort	8	2.6

TABLE IX.—*Diarrhoea.*
(Diarrhoea occurred in 14 cases out of the 323.)

Diarrhoea.	No. of Cases	Percentage.
Slight	14	4.4

Diarrhoea occurred in 6 per cent. of the cases of duodenal ulcers.

TABLE X.—*Constipation.*
(Constipation occurred in 43 cases out of the 320.)

Constipation.	No. of Cases.	Percentage.
Slight	41	12.8
Severe	2	0.6

Constipation occurred in 16.9 per cent. of the cases of duodenal ulcers.

TABLE XI.—*Food Able to be Taken.*
(Information as to diet was given in all of the 320 cases.)

	No. of Cases.	Percentage.
Full diet	252	78.8
Certain articles of diet avoided	68	21.2

In the majority of the 68 cases in which some modification of the diet was necessary, only one or two articles of diet had to be avoided on account of their producing flatulence or indigestion. Among these cases 42 avoided some form or forms of protein food (beef, mutton, veal, pork, bacon, cheese, eggs), and 26 avoided some form or forms of carbohydrate food (vegetables, pastry, fats, fruit). Therefore of those on a modified diet about 62 per cent. were obliged to avoid some form of protein, and 38 per cent. some form of carbohydrate. Among the duodenal ulcers 37.9 per cent. were obliged to avoid certain articles of diet. The relative percentages of those that avoided proteins or carbohydrates are practically the same in the cases of both duodenal and pyloric ulcers.

Information as to the time of return to work was given in 275 cases. In a certain number of other cases it was stated the individuals were either of the leisured classes doing no work, or were past the age for work.

TABLE XII.—*Time of Return to Work after Operation.*

Time of Return to Work.	No. of Cases.	Percentage.
1 to 2 months	101	36.7
2 to 3 ,, ...	121	44.0
3 to 4 ,, ...	18	6.6
4 to 6 ,, ...	18	6.6
Over 6 ,, ...	17	6.1

This table shows that 80.7 per cent. returned to work within three months from the date of the operation. With regard to those that did not return to work till after three months, the reasons given in the majority of the cases were that there was no immediate necessity for return, or that work was not available at the time. In the case of the duodenal ulcers 73.1 per cent. returned to work within three months from the date of the operation.

TABLE XIII.—*Work Capacity.*
(Information on this point was given in 269 cases.)

Work Capacity.	No. of Cases.	Percentage.
Full work	244	90.7
Light work	25	9.3

In the case of the duodenal ulcers, 94 per cent. returned to full work.

TABLE XIV.—*Weight after Operation.*
(Information on this point was given in 294 cases.)

Weight.	No. of Cases.	Percentage.
Gained	216	73.5
Constant	64	21.8
Lost	14	4.7

The percentages are practically the same for duodenal and pyloric ulcers.

TABLE XV.—*Condition of Health and Well-being after Operation.*
(Information on this point was given in 292 cases.)

Health.	No. of Cases.	Percentage.
General improvement of health	275	94.2
Fair improvement of health	10	3.4
No improvement of health	7	2.4

The percentages are practically the same for duodenal and pyloric ulcers.

Subsequent Medical Treatment Required.

Among the 320 cases subsequent medical treatment was necessary in 14—that is, 4.4 per cent. of the cases. Among these occasional bismuth and sodium bicarbonate were required in twelve cases, an occasional laxative in one case, and an occasional astringent in one case.

TABLE XVI.—*Number of Years after Operation during which Patients were under Observation, or during which Reliable Information was Obtained.*
(Definite information on this point was given in 294 cases.)

Years under Observation.	No. of Cases.	Percentage.
2 to 3 years	7	2.4
3 to 4 ,, ...	25	8.8
4 to 5 ,, ...	81	27.6
5 to 6 ,, ...	67	22.8
6 to 7 ,, ...	40	13.6
7 to 8 ,, ...	43	14.6
8 to 9 ,, ...	30	10.2

This table shows that 89 per cent. of the patients were under reliable observation for periods ranging from four to nine years.

Classification of Results.

The classification adopted is the same as that used in connexion with duodenal ulcers (see Part I, *British Medical Journal*, December 7th, p. 1076).

TABLE XVII.—*Classification of Results.*
(The results returned enabled this classification to be made in 296 cases.)

Classification.	No. of Cases.	Percentage.
Very good	226	76.3
Good	48	16.2
Fair	12	4.1
Poor	10	3.4

From this table it will be seen that the late results of the operation were very satisfactory in 92.5 per cent. of the cases. In the duodenal ulcer series the late results of the operation were very satisfactory in 89.5 per cent. of the cases.

Secondary Gastro-jejunal Ulcers.

Number.—Three ulcers of this type—that is, 0.9 per cent.—occurred among the 320 cases in which after-histories were given.

Sex.—All males.

Age.—All occurred between 30 and 50 years of age.

Symptoms.—Pain occurred in all cases, vomiting in two, and haemorrhage in one.

TABLE XVIII.—*Periods after the Gastro-enterostomy Operation at which Symptoms Occurred Necessitating Operation for Gastro-jejunal Ulceration.*

Period.	No. of Cases.
2 years	2
5 ,, ...	1

Sites of the Gastro-jejunal Ulcers.—Not stated in any of the cases.

Results of Operations for the Gastro-jejunal Ulcers.—Good recovery in all the cases.

Operations Performed.—Partial gastrectomy in two cases. Suture of perforated ulcer in one case.

Second Operations Required for Intercurrent Lesions after Gastro-enterostomy.

Nine of these operations—that is, 2.8 per cent.—were required among the 320 cases in which after-histories were given. Eight of the patients were between 30 and 70 years of age. Particulars of the individual cases are given as they could not be tabulated.

1. Serious vomiting five days after first operation from obstruction. Entero-enterostomy done. Recovery.

2. Cyclical vomiting eleven days after first operation from obstruction. Entero-enterostomy done. Recovery.

3. Pain and vomiting one year after first operation from acute kinking of proximal loop causing obstruction and peritonitis. Laparotomy, but too collapsed for further operation. Death.

4. Discomfort and flatulence one and a quarter years after first operation from partial obstruction of jejunum by omental band. Division of omental band. Recovery.

5. Acute intestinal obstruction one and a quarter years after first operation from adhesion of portion of intestine to abdominal wall. Removal of adhesions. Recovery.

6. Pain and vomiting three years after first operation from large ulcer on lesser curve. Partial gastrectomy done. Death three days later.

7. Diarrhoea four years after first operation from perforation of efferent loop into transverse colon, associated with adhesions. Separation of jejunum from transverse colon and closure of both openings done. Recovery.

8. Pain and vomiting four years after first operation from gastric ulcer. Ulcer cauterized and omental graft. Recovery.

9. Pain four years after first operation from duodenal ulcer. Invagination of ulcer. Recovery.

Secondary Haemorrhage.

(Not stated as due to anastomotic ulcer.)

Number.—Four cases of secondary haemorrhage—that is, 1.2 per cent.—occurred among the 320 cases in which after-histories were given.

Sex.—All males.

Age.—All the cases were between 30 and 50 years of age.

Nature of Haemorrhage.—Haematemesis in two cases; melaena in one case; haematemesis and melaena in one case.

Periods at which Haemorrhage started after the Gastro-enterostomy Operation.—The periods respectively were two years, three years, three and a half years, and five and a half years.

Treatment.—Two had rest and medical treatment; two had rest and light diet.

Results.—Good recovery in all cases.

Analysis of the Post-operative Mortality.

Among the 454 cases of pyloric ulceration six deaths occurred from some other lesion some years after the operation and quite unconnected with it. As these six cases up to the time of death were free from all symptoms connected with the ulceration, the deaths are not included among the post-operative deaths. The number of post-operative deaths out of the 454 cases was 12—that is, 2.6 per cent. These are the deaths that occurred as a direct result of the operation of gastro-enterostomy, and do not include the deaths from second operations performed for some intercurrent lesion, which have already been enumerated in the preceding part of this report.

Sex.—Of the twelve deaths, 83 per cent. occurred amongst males and 17 per cent. amongst females—a ratio which is roughly the same as in the case of duodenal ulcers.

TABLE XIX.—*Age Incidence of Deaths.*

Age.	Percentage of Deaths.
30-40 years	33
40-50 ,, ...	25
50-60 ,, ...	25
60-70 ,, ...	17

TABLE XX.—*Time of Occurrence of Death after Operation.*

Time.	Percentage.
1-6 days	58
7-14 ,, ...	25
2-3 weeks	17

Among the duodenal ulcers, 64 per cent. of the deaths occurred between one and six days after operation. Among the 12 cases haemorrhage occurred as a symptom prior to operation in 17 per cent. It would appear from these figures, as with the corresponding figures for duodenal ulcers, that the risk of a fatal post-operative result is not increased by the occurrence of haemorrhage prior to operation.

TABLE XXI.—*Cause of Death.*

Cause of Death.	No. of Cases.
Pneumonia	3
Haemorrhage	2
Shock	2
Peritonitis	2
Heart failure	1
Gangrene of transverse colon	1
Cause not stated	1

Carcinoma Developing at the Site of Ulcer.—No case was reported in the whole series.

BRIEF SUMMARY OF RESULTS.

Pyloric ulceration is about three times more common in males than in females. The report on duodenal ulceration showed that it was about five times more common in males than in females.

The liability to pyloric ulceration rapidly diminishes after 50 years of age, as is also the case with duodenal ulceration.

Posterior gastro-enterostomy with or without embedding or removal of the ulcer was the operation performed in 94.7 per cent. of the cases. This is practically the same percentage as with the duodenal ulcers previously reported on.

Hyperchlorhydria was present in 80.5 per cent. of the cases submitted to test meals, as compared with 86.2 per cent. in the case of duodenal ulcers.

Neither diarrhoea nor constipation is a marked result of the operation, but, as in the case of duodenal ulcers, constipation of a mild character is more frequent than diarrhoea.

About one-fourth of the patients operated on made some slight modification in diet. Of these, 62 per cent. avoided some form of protein, and 38 per cent. some form of carbohydrate. Almost precisely the same relative figures occurred among the duodenal ulcers.

Some 80 per cent. of the patients returned to full work within three months of the date of the operation. This is a slightly higher percentage than in the case of the duodenal ulcers.

General improvement of health and well-being occurred in all but a few cases.

The results of the operation were satisfactory in about 92 per cent. of the cases.

Secondary gastro-jejunal ulcers occurred in 0.9 per cent. of the cases, as compared with an occurrence of 2.8 per cent. in the cases of duodenal ulceration.

Secondary haemorrhage occurred in 1.2 per cent. of the cases, but with no fatal result, as compared with an occurrence of 2.4 per cent. in the cases of duodenal ulceration, also with no fatal result.

The post-operative mortality was 2.6 per cent., the mortality being highest in patients from 30 to 40 years of age. The majority of deaths occurred within seven days of the date of operation. The post-operative mortality for duodenal ulcers was 5 per cent. If the 995 cases of duodenal ulcers and the 454 cases of pyloric ulcers are massed together, then the combined post-operative mortality would be 4.3 per cent.

No case of carcinoma developing at the site of an ulcer was reported in the whole series.

PART III.—PERFORATED DUODENAL AND PYLORIC ULCERS.

There were 112 reports of the results of operations for perforated duodenal ulcers, and 20 similar reports of perforated pyloric ulcers were received. As the results of the operation in the two classes were practically the same, the numbers have been massed together in order to avoid separate reports. The answers to the various questions have been carefully collated, and the results are embodied in the following tables.

TABLE I.—*Sex Incidence.*

Number of cases	132
Males (percentage)	93.2
Females (percentage)	6.8

TABLE II.—*Age Incidence (at Time of Operation).*

Age	Percentage.
20-30 years	15.1
30-40 ,,	34.1
40-50 ,,	32.6
50-60 ,,	11.4
60-70 ,,	6.8

This table shows that the age incidence of perforation roughly corresponds with the age incidence of the occurrence of ulcers (see Parts I and II).

TABLE III.—*Type of Operation.*

Type of Operation.	No. of Cases.	Percentage.
Posterior gastro-enterostomy and suturing	122	92.4
Posterior gastro-enterostomy and invagination	6	4.6
Posterior gastro-enterostomy and excision	4	3.0

In addition, appendicectomy was performed in 6.8 per cent. of the cases.

TABLE IV.—*Reasons for Operating.*

Symptoms.	No. of Cases.	Percentage.
Pain	132	100.0
Vomiting	18	13.6
Melaena	5	3.8
Haematemesis and melaena	3	2.3

The following are the direct results of operation in the 132 cases.

TABLE V.—*Results of Operation.*

Result.	No. of Cases.	Percentage.
Good recovery	112	84.9
Delayed recovery	2	1.5
Death	18	13.6

AFTER-HISTORIES OF THE OPERATION CASES.

The 132 cases dealt with in the above table include 90 cases in which the after-histories were given, 13 cases in which the after-histories consisted only of statements that the patients were in good health at some specified times after operation, and 29 cases in which no after-history was given. For the preparation of the after-history statistics the 90 cases only are employed.

TABLE VI.—*Pain or Other Discomfort after Food.*
(Information on these points was given in 70 cases.)

	No. of Cases.	Percentage.
No pain or discomfort	48	68.6
Occasional slight pain or discomfort	14	20.0
Temporary pain or discomfort (in most cases soon after operation)	6	8.6
Severe pain or discomfort	2	2.8

Diarrhoea.—Slight diarrhoea occurred in one case out of the 90—that is, in 1.1 per cent.

Constipation.—Slight constipation occurred in 14 cases out of the 90—that is, in 15.5 per cent.

TABLE VII.—*Food Able to be Taken.*
(Information as to diet was given in the 70 cases.)

	No. of Cases.	Percentage.
Full diet	74	82.2
Certain articles of diet avoided	16	17.8

A rather higher percentage of patients were able to take full diet than among the cases of non-perforated duodenal and pyloric ulcers.

TABLE VIII.—*Time of Return to Work after Operation.*
(Information on this point was given in 68 cases.)

Time of Return to Work.	No. of Cases.	Percentage.
1 to 2 months	25	36.7
2 to 3 ,,	19	28.0
3 to 4 ,,	7	10.3
4 to 6 ,,	14	20.6
Over 6 ,,	3	4.4

This table shows that 64.7 per cent. returned to work within three months from the date of the operation. With regard to those that did not return to work till after the three months, the reasons given in the majority of the cases were that there was no immediate necessity for return, or that work was not available at the time. The corresponding figures among the non-perforated ulcers of return to work within three months were 73.1 per cent. among the duodenal ulcers, and 80.7 per cent. among the pyloric ulcers.

TABLE IX.—*Work Capacity.*
(Information on this point was given in 68 cases.)

Work Capacity.	No. of Cases.	Percentage.
Full work	62	91.2
Light work	6	8.8

The corresponding figures among the non-perforated ulcers of return to full work were 94 per cent. among the duodenal ulcers, and 90.7 per cent. among the pyloric ulcers.

TABLE X.—*Weight after Operation.*
(Information on this point was given in 70 cases.)

Weight.	No. of Cases.	Percentage.
Gained	41	58.6
Constant	23	32.8
Lost	6	8.6

TABLE XI.—*Condition of Health and Well-being after Operation.*
(Information on this point was given in 70 cases.)

Health.	No. of Cases.	Percentage.
General improvement of health	61	87.1
Fair improvement of health	9	12.9

As regards the condition of health after operation there is only a slight difference as compared with the non-perforated ulcers.

TABLE XII.—*Number of Years after Operation during which Patients were under Observation, or during which Reliable Information was Obtained.*
(Definite information on this point was given in 70 cases.)

Years under observation.	No. of Cases.	Percentage.
3 to 4 years	13	18.6
4 to 5 ,,	13	18.6
5 to 6 ,,	18	25.7
6 to 7 ,,	17	24.3
7 to 8 ,,	9	12.8

This table shows that 81 per cent. of the patients were under reliable observation for periods ranging from four to eight years.

Classification of Results.

The classification adopted is the same as that used in connexion with duodenal and pyloric ulcers in Parts I and II.

TABLE XIII.—*Classification of Results.*
(The results returned enabled this classification to be made in 70 cases.)

Classification.	No. of Cases.	Percentage.
Very good	52	74.3
Good	10	14.3
Fair	8	11.4

From this table it will be seen that the late results of the operation were very satisfactory in 88.6 per cent. of the cases. The corresponding figures among the non-perforated ulcers were 89.5 per cent. among the duodenal ulcers, and 82.5 per cent. among the pyloric ulcers.

Secondary Gastro-jejunal Ulcer.

Only one case, that of a male 39 years of age, occurred in the whole series, the symptoms starting two to three years after the gastro-enterostomy operation. The gastro-jejunal ulcer was found perforated, the perforation was closed, and good recovery resulted.

Second Operations Required for Intercurrent Lesions.

Three of these operations—that is, 3.3 per cent.—were required among the 90 cases in which after-histories were given. All the cases were between 40 and 50 years of age. Particulars of the individual cases are given.

1. Symptoms (not given) occurred one and a half years after the first operation from inadequate stoma. Repair of stoma and jejunostomy done. Recovery.
2. Intestinal obstruction occurred three years after the first operation from kinking of anastomosis. Old gastro-enterostomy undone to allow reduction of displaced small intestine, and fresh gastro-enterostomy performed. Recovery.
3. Symptoms (not given) occurred six years after the first operation from inadequate stoma. Enlargement of stoma done. Recovery.

Secondary Haemorrhage.

Only one case, that of a male 25 years of age, occurred in the whole series, haematemesis and melaena starting six years after the gastro-enterostomy operation. Rest and medical treatment were employed, and good recovery resulted.

Analysis of the Post-operative Mortality.

The number of post-operative deaths out of the 132 cases was 18—that is, 13.6 per cent.

SEX.—Of the deaths, 17 occurred among males.

TABLE XIV.—*Age Incidence of Deaths.*

Age.	Percentage of Deaths.
20-30 years	11
30-40 ,, ...	22
40-50 ,, ...	33
50-60 ,, ...	6
60-70	28

TABLE XV.—*Time of Occurrence of Death after Operation.*

Time.	Percentage.
1-6 days	50
7-14 ,, ...	17
2-3 weeks	17
7-8 ,, ...	11
Not stated	5

Among the 18 cases haemorrhage occurred as a symptom prior to operation in 11 per cent. of the cases. It would therefore appear, as in the cases of the non-perforated duodenal and pyloric ulcers, that the risk of a fatal post-operative result is not increased by the occurrence of haemorrhage prior to the operation.

TABLE XVI.—*Cause of Death.*

Cause of Death.	No. of Cases.
Shock	5
Peritonitis	5
Haemorrhage	2
Pneumonia	1
Pyaemia	1
Cause not stated	4

Carcinoma Developing at the Site of Ulcer.—No case was reported in the whole series.

BRIEF SUMMARY OF RESULTS.

Perforation occurs much more frequently in males than in females.

The age incidence of perforation roughly corresponds with the age incidence of the occurrence of ulcers.

About 65 per cent. of the cases returned to full work within three months of the date of the operation.

The results of the operation were satisfactory in about 89 per cent. of the cases that survived.

The post-operative mortality was 13.6 per cent., the mortality being highest in patients from 30 to 50 years of age. One-half of the deaths occurred within seven days of the date of operation.

No case of carcinoma developing at the site of an ulcer was reported in the whole series.

England and Wales.

Public Health and the Local Government Act.

IN a Chadwick public lecture on public health law and administration introduced by the Local Government Act, 1929, Mr. William A. Robson, Ph.D., LL.M., said that this Act was introduced primarily as a financial measure intended to relieve the burden of rates on industry. It was clear, however, that the public health aspects of the Act were of the greatest importance, although many of them did not receive adequate attention when the bill was passing through Parliament. Abolition of the boards of guardians and the transfer of their functions to the general local authorities was accompanied by a provision which enabled county and county borough councils to provide assistance under a number of social service statutes in place of relief under the Poor Law. Where this was taken advantage of as regards sick persons the great Poor Law hospitals and infirmaries would be transformed into municipal general hospitals for the use of the whole body of citizens. Thus, almost by a side-wind, the whole hospital question would be radically changed both as regards law and administration. At the same time, the Act provided for a survey of the existing provision of infectious disease hospitals, and stringent means were taken to compel the formulation and carrying out of schemes to secure "adequate hospital accommodation" for infectious disease. The so-called "Onslow clauses" of the Act contemplated an extensive reorganization of areas and the elimination of authorities unfit or unwilling to carry out the duties. Public health questions were the chief consideration which led to the passing of this part of the Act, and local authorities unable to provide the sanitary services *needed for* the "ordinary requirements for the general community" might be regarded as doomed to extinction. A most important series of changes was introduced in the group of services affecting maternity and child welfare. For the first time local authorities were permitted to provide places "for the reception of pregnant women," this modifying a decision of the courts that pregnancy could not be regarded as sickness. The duties imposed under the Children Act were henceforward to be carried out by *authorities responsible* for maternity and child welfare, and lack of *co-ordination* between the school medical service and maternity and child welfare authorities was to be *rectified*. The registration service, which Chadwick placed for the first time on a sound legislative basis, was to be associated

from the Poor Law and brought into a more organic relation with the public health system. Most important of all, the public health service would in future be manned only by full-time medical officers. All these far-reaching changes were reforms on which the local authorities, the medical profession, and the general community might congratulate themselves. The danger spot in the Act, so far as public health was concerned, lay in the financial provisions. But the public health service was now of such vital importance that no legal or administrative provision would be permitted to endure which did not yield beneficial results in terms of life and health.

Vocational Guidance.

At a recent meeting of the London Association of the Medical Women's Federation, with Miss F. M. Huxley in the chair, an address on vocational guidance was given by Professor Winifred Cullis. She gave an account of the establishment of the National Institute of Industrial Psychology, which grew out of the Fatigue Research Committee constituted during the war, and showed how valuable the institute was proving at the present time, demonstrating the importance of the psychological factor in industry, and its application to the workers in individual firms. The work done by the institute was paid work, but no profit was made, for the balance was used for research. Its advice had been sought for various reasons—because of lessened output and, on behalf of a firm of caterers, because of excessive breakages by the workers. By the correction of details of little apparent importance in routine work, and by skilled observation of the workers, most dramatic improvements had been effected. As a natural outcome of this work help was given to individuals in vocational selection, and tests had been devised which would show whether a prospective worker had a special aptitude for a given type of work. This was of great value, for otherwise haphazard and unscientific methods of selecting workers were employed. Vocational selection tests would show only whether a person was fitted for one particular type of occupation. The system had now been extended to embrace a scheme whereby an all-round examination would test both the innate intelligence and those qualities which could not be tested by a written examination, but the assessment of which was of great importance in determining the most appropriate type of occupation for a particular person. Experimental work on a large scale had been done on a group of elementary school children. Two hundred children leaving school were chosen. One hundred of these were tested and advised as to the type of occupation in which they would do best. Wherever possible these children took up the suggested work. The other hundred were not tested, and did not take up selected work. At the end of two years it was found that the children in the guided group had changed their occupation on an average twice, and those in the unguided group four times. The average wage in the guided group was considerably higher than in the other. A further group of six hundred children was now being investigated. The ages at which the tests were found to be of most practical use were from 16 to 18. In illustration of the value of vocational guidance tests Professor Cullis quoted recent examples of many people who had come to the institute for help in the choice of a career. Workers could be divided into "sprinters" and "stayers," and it was important to find the type of work for which each was suited. By making a more extensive use of vocational guidance tests she was convinced that there would be fewer round pegs in square holes, and the sum of the world's happiness would be appreciably increased.

The Home Ambulance Service.

In its report for the three months ending September 30th, the home service ambulance committee of the Joint Order of the Council of the Order of St. John of Jerusalem and the British Red Cross Society emphasizes the financial difficulties inevitably associated with its commendable activities. The committee possesses at the moment 268 ambulance stations in the country, and seventy-six other stations are affiliated to it, the total being 344. The number of sick and injured persons carried during the quarter under review was over 29,000; in spite of the fact that the committee has now rather fewer ambulances, several having been taken over by other agencies, there is but little reduction in the work, the average number of invalids carried in an ambulance during the year showing a continued increase. It is pointed out in the report that the fees recoverable in respect of carrying these patients do not suffice to meet the cost of running the ambulance and providing for its replacement when worn out. Efforts have therefore to be made repeatedly to raise additional funds by such means as weekly contributory schemes, house-to-house collections, whist drives, bazaars, and flag days. Attention has previously been called in our columns to the close relationship which has to be maintained by this ambulance service with the police, and also the additional work thrown upon it by street accidents. Several of these ambulance units have accepted the additional responsibility of dealing with such accidents, and have incurred another liability also by arranging for road patrols and the installation of first-aid boxes in roadside huts. In view of the devotion and public spirit shown by those who so willingly sacrifice much of their leisure in order to perform voluntarily one of the most valuable social services of the day, it is to be hoped that a greater measure of financial support will be forthcoming in the future from the general public.

Courses at the Maudsley Hospital.

The spring post-graduate courses at the Maudsley Hospital, London, will begin on January 7th, 1930, and comprise the physiology and anatomy of the nervous system, and psychology. The various lectures and demonstrations will be held in the afternoons of certain days in the week, commencing at 2.30, with the exception of the biochemical lectures and demonstrations, which will start at 4 o'clock. Dr. F. L. Golla will deliver twelve lectures on the physiology of the nervous system, and four lectures and demonstrations on physiological psychology. The biochemical aspects of mental disorders will be discussed in four lectures and demonstrations by Mr. S. A. Mann. Twelve lectures will be delivered by Professor G. Elliot Smith on the anatomy of the nervous system, and practical instruction, with demonstrations, will be provided by Mr. Charles Geary. A course of eight lectures on psychology will be held by Dr. Henry Devine, and subsequently there will be a course of practical instruction. The second part of the spring course will occupy the months of March, April, and May, and will include eight lectures on the psychoneuroses by Dr. Bernard Hart; twelve lectures on morbid psychology, by Dr. Edward Mapother; four lectures on the pathology of mental diseases, by Dr. Golla; and four demonstrations in pathological anatomy, by Mr. Charles Geary. Sir Hubert Bond will discuss the legal relations of insanity and treatment in four lectures, and Dr. F. C. Shrubsall will devote six lectures to the practical aspect of mental deficiency. Six lectures on crime and insanity will be given by Dr. W. Norwood East, and three lectures on therapeutics by Dr. A. A. W. Petrie. In connexion with this course Dr. Edward Mapother will give six demonstrations in clinical psychiatry, while twelve clinical demonstrations in neurology will be arranged by Drs. F. L. Golla and F. M. R. Walshe. Mr. R. Foster Moore will devote two lectures to abnormalities of the fundus oculi, and Mr. Mann will give two demonstrations of laboratory methods. Further information about this course may be obtained from the director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

"Cancer Annexe" at Westminster Hospital.

Among the hospitals which are making special provision for cancer patients is the Westminster Hospital, close to the Houses of Parliament. This hospital has been one of the pioneers in the radium treatment of cancer, and recently was entrusted by the National Radium Commission with a 4-gram "bomb" of radium for mass irradiation. Some months ago the governors prepared plans for a separate radium annexe in order that their responsibilities with regard to this possession might be more adequately discharged. The annexe is to be a complete and self-contained radium hospital, with beds which, it is estimated, will accommodate annually 500 patients of all

classes. The cost of maintenance will add nearly £5,000 a year to the annual expenditure, and there is a deficit of £9,000 in the fund required for the initial equipment. On account of this grave financial position, the house committee has been compelled to suspend certain of its plans. A scheme has been evolved whereby one thousand founders may be created, each by a donation of not less than £10 or an annual subscription of two guineas. The names of these founders will be permanently recorded on the annexe, with H.R.H. The Prince of Wales heading the list. The Speaker of the House of Commons is appealing on behalf of this effort, for the hospital has long had very close association with Parliament; and many cases of sudden illness in the House have been treated there.

Scotland.

Edinburgh Hospital Problems.

At the general meeting of the League of Subscribers to the Royal Infirmary of Edinburgh, held on December 3rd, Sir David Wallace made a statement about the present hospital accommodation. He pointed out that on November 1st the number of patients waiting for admission to this institution was 3,009, an increase of 559 over the figure at the same period of last year. He explained that the list was not so formidable as it appeared, and that no urgent case would ever be refused admission. The board of managers valued immensely the work done by the League of Subscribers, whom he congratulated upon the increase of subscriptions in the past year. The infirmary had dealt with a larger number of patients than in any previous year, the total treated in the wards being over 19,800, of whom 4,700 were medical cases and 14,200 surgical. The total of 67,623 out-patients showed an increase of 5,538 over the number in the preceding year. The financial position was gratifying, the total ordinary income having been £114,896 and the extraordinary income £139,382, a total of £254,278. The ordinary expenditure had been £143,684 and extraordinary expenditure £18,612, a total of £162,256, leaving a credit balance with the general fund of £91,982. Ten years ago the in-patients had numbered 12,499, of whom 4,056 were medical cases and 8,443 surgical. The medical cases were therefore practically the same in number now, while surgical cases had increased by 6,000. One explanation of this increase was that in contrast to the unwillingness of patients some years ago to go to hospital for operations, practically every patient who was to be operated on now wished to have this done in hospital. With regard to the waiting list, of the 3,000 cases 516 awaited admission to the ear and throat department because there was at the present time apparently a desire for tonsils and adenoids to be removed at an early stage. About three years ago this department had been enlarged, and the managers had then made a ruling that until the list was cleared off the extra beds were to be used for country cases only. As a result, within a year the list was cleared off, and he believed that the present large waiting list could be diminished as the last one had been. In general, cases put on the waiting list were those in which delay was not harmful to the patient, but, owing to the pressure of emergency cases, they were liable to be kept waiting for an unduly long time. The Astley-Ainslie Institute, which at present had 98 beds available and by springtime would have 34 further beds, would ease the situation to some extent. A proposal was now under consideration for the establishment of a radium institute, which would supply 36 beds. It was proposed to use for this purpose Beechmount, a property belonging to the infirmary in the out-skirts of Edinburgh, and this would be an integral part of the infirmary and ease the situation of the waiting list. The Edinburgh Royal Infirmary had recently been selected as the institution for the first radium institute in Scotland. The infirmary hoped to gain yet further relief in the matter of accommodation by the establishment of the hospital for cripples, which was in process of erection at Fairmilehead. It was hoped that the regional committee of the south-eastern area of Scotland which had been formed would be in intimate association with the new public health authorities that would come into being under the operation of the new Local Government Act in 1930, and also that by co-ordination and co-operation between hospitals, both voluntary and public, more rapid admission and more efficacious treatment of patients would be effected. Sir David Wallace was convinced, however, that any injury—mental or physical—to the patients on the waiting list was much less than might be supposed. Referring to motor accidents, he said that during the past year 443 such patients had been treated at a cost to the infirmary of £3,223. A report by Mr. Russell-Patan, organizing secretary of the League of Subscribers, stated that a total of £21,564 had been gathered from 1,410 groups of league subscribers in small sums. Of this total, Edinburgh was responsible for £15,942, while country district had subscribed £5,622.

The Causes of Mental Disease.

An address was delivered, as one of the Combe Trust public health lectures, by Dr. W. R. D. Fairbairn in Edinburgh on November 27th. The lecturer pointed out that, dating from the appointment of Pinel as physician to the Bicêtre Asylum in Paris in 1792, the attitude of society towards the insane had undergone a marked change. Till that time the insane were kept in confinement under indescribable conditions, but Pinel was original enough to regard them as patients requiring medical treatment instead of as criminals. During the nineteenth century, further, the scientific study of insanity had originated, and the progress of medical science influenced the attitude of society towards the insane. The original conception of insanity had been attributed to possession by evil spirits, and, except among certain enlightened thinkers, such as Hippocrates, the demoniacal explanation remained current during the Christian era until the rise of modern scientific medicine. This change had been reinforced by the study of the nervous system, which revealed a close connexion between mental states and brain processes. Psychiatry had gradually been developed during the nineteenth century upon the basis that mental disease was essentially a disease of the brain, caused by such agencies as toxins. Undoubtedly certain mental diseases had been definitely established upon a physical basis—for example, general paralysis of the insane—but there were other forms of insanity for which this did not hold true. There had gradually arisen in recent years a movement to substitute in such cases a psychological for a physical interpretation, and it was coming to be recognized that mental disease might arise from purely mental causes. The importance of the psychological interpretation of mental disease lay in the possibility this provided for preventing its onset. Tendencies which became subject to repression first manifested themselves in childhood, and the prevention of mental disease therefore depended to a great extent upon the enlightenment of parents and educators.

Chemistry in Daily Life.

The progress which is being made on the human side of chemistry was outlined at the opening meeting of the Pharmaceutical Society of Great Britain in Edinburgh on November 22nd, by Professor James B. Kendall, who was recently appointed to the chair of chemistry in the University of Edinburgh. Mr. Charles Simpson, chairman of the executive of the North British branch of the Pharmaceutical Society, presided. Professor Kendall said that our commercial prosperity, as well as much of our health and comfort, depended upon the application of chemistry to problems presented by dye stuffs, fertilizers, artificial silk, fuel conservation, new alloys, synthetic rubber, and many other household necessities. The public required to be educated about the significance of chemistry in daily life. The Tyrian purple of the ancients was now supplanted by a synthetic dye of identical composition, but with the bromine atoms at different points in the molecule. A natural drug like cocaine was replaced by a synthetic product like novocain, which possessed all the desirable and none of the undesirable properties of the original, merely by shifting certain groups from the molecule and inserting others. In artificial silk or rayon the

chemist had provided the feminine part of the world with a material which was much cheaper than natural silk and much more attractive than cotton. The most rapid progress in chemistry, however, at present was being made upon the boundary between chemistry and medicine. Mention might be made, in particular, of the work of Dr. F. B. Power of the Wellcome Research Laboratories on the constituents of chaulmoogra seeds and chaulmoogric acid, which laid the foundation upon which the present-day treatment of leprosy rested. Chemotherapy, or the destruction of invading germs through the administration of chemicals, had been described as the hope of mankind, and specifics against sleeping sickness, malaria, and general paralysis were now rapidly cutting down the mortality due to these diseases, while promising preliminary results were being obtained against pneumonia and tuberculosis. The common cold remained one of the perplexing problems, and Mr. Francis P. Garvan, an American philanthropist, had donated a large sum of money to Johns Hopkins University for intensive study of its prevention and cure. This chemical foundation had recently issued a remarkable volume entitled *Chemistry in Medicine*, which discussed the possibilities of advance in medical science through further co-operation between the chemist and the physician. If some similar effort could be made in this country the community would gain a clearer understanding of the chemist, and would appreciate more fully the human side of chemistry.

Services of Zoology to the Community.

Professor J. H. Ashworth, D.Sc., F.R.S., in a recent address to the Edinburgh Rotary Club, dealt with the practical applications of zoology. He mentioned that every year more than 300 students and graduates passed through this department of Edinburgh University, of which he is the head. Every student of medicine attended a course of zoology in his first year, and this was of great value as giving him a trained outlook on the living organism. Medical graduates to the number of about forty every year received instruction in entomology and parasitology in connexion with tropical medicine. The lecturer pointed out that new knowledge had robbed plague of its powers, for though there would still be outbreaks, they could be circumscribed through the knowledge that was now available regarding the structure and biology of the plague-flea. In regard to food supply, research work on sea fisheries had been of the greatest importance. Research was now being directed to the life-history of diatoms which formed the food of crustacea, which in turn formed the food of fish, while these were an important part of the food supply of man. An example of the direct service rendered to the community by zoology was found locally in a problem of the Edinburgh Electricity Generating Station, where the entry and growth of mussels in three large tunnels which conducted water for condensing purposes from and to the sea, tended to block these up in a short time. The mussels invaded the tunnels in the larva stage and chemical measures were too expensive for their destruction. Finally it was found that a current of water heated to 90° F. from the condensers passed down each tunnel for twelve hours once in four weeks during the breeding season of mussels, proved entirely effective in preventing their growth.

An Ancient Aberdeen Practitioner.

At a recent meeting of the Edinburgh Bibliographical Society Mr. Walter B. Menzies, librarian, Marischal College, Aberdeen, delivered a lecture upon Alexander Read, physician and surgeon, 1580–1641. Read was a graduate of Aberdeen University who studied medicine in France, practised in various places, and eventually settled in London. Between the years 1632 and 1634 he lectured every Tuesday on anatomy and surgery in the Barber-Surgeons Hall. He published his lectures in book form, and when he died in 1641 bequeathed his library to Marischal College. Aberdeen University accordingly possessed a typical library of a practising surgeon in the time of James I and Charles I. Read had apparently kept himself well up to date, and possessed such books as William Harvey's *Exercitatio Anatomica de Motu Cordis* of 1628, and the *Animadversions* on the same by Dr. James Primrose in 1630. These were underlined throughout in faded red ink, and had Read's neatly written marginal notes. There were in his collection five volumes of Daniel Sennertus, an authority who had been the first to introduce chemistry as a subject of the medical curriculum. The library also contained a copy of the alchemical works of Andreas Libavius, Frankfurt, 1606, the foremost scholar of the day in that science. Read's *Treatise on Wounds* and other works had been very popular in the civil war, and had been republished when the country was once more at peace.

Ireland.

Promotion in Free State Mental Hospitals.

At the last meeting of the committee of the Clonmel Mental Hospital a letter was read from the Minister of Local Government and Public Health in reference to the recent promotion of Dr. Fitzgerald to the position of resident medical superintendent, in place of the late Dr. Harvey, stating that the appointment was not one to which the provisions of Section 5 of the Local Authorities (Officers and Employees) Act of 1926 could with advantage be applied. The Minister was not prepared to alter his decision in the matter, and suggested that the committee should request the Local Appointments Commissioners to recommend a suitable person for the position. After the discussion, in which the action of the Minister was strongly criticized, the committee unanimously agreed to adhere to its previous decision in appointing Dr. Fitzgerald, and to send a deputation to interview the Minister in the matter. A similar letter from the Department of Local Government and Public Health has been received by the committee of the Sligo and Leitrim Mental Hospital, which had also appointed, by promotion, its assistant resident medical superintendent to fill the higher office. It appears that the Minister is in favour of the Appointments Commissioners making the selection from all resident medical superintendents in the *Free State Medical Register* who are qualified for the office, and not limiting it to the promotion of the assistant medical superintendent of the mental hospital in which the vacancy exists. This decision on the part of the Minister, however, seems inconsistent with his limitation of promotion of medical officers under health boards to the county in which the vacancy occurs.

Abuse of Dispensary Tickets.

At a recent meeting of the County Wexford health board, a letter was read from the Local Government and Public Health Department with reference to the issue of dispensary tickets in New Ross. The letter stated that according to Dr. Sterling Berry, medical inspector, the majority of the tickets issued have been for persons residing in the New Ross urban district, where there are thirteen wardens, two members of the Board of Health, and a home assistance officer empowered to issue tickets. The population of the dispensary district is approximately 8,000, of which about 5,000 are resident in the urban area. The number of tickets issued during the half-year ended March 31st, 1929, was 1,495, including 567 visiting tickets. For the half-year ended September 30th, 1929, the number was 1,232, and of these 313 were visiting tickets. This gives a total issue of 2,727 tickets for the year, and it is estimated that over 2,000 of these were presented by residents in the urban area. Compared with other districts, the number of tickets issued in the New Ross urban district is abnormal. When checking the register, the inspector observed that visiting tickets appeared to have been given in many cases when, from the ailments from which the recipients suffered, it was quite evident that tickets for attendance at the dispensary would have sufficed. The Minister is of the opinion that tickets are very carelessly issued by some of the New Ross wardens, and he approves of the attitude of the board that due care should be exercised by wardens and others in the issue of tickets for medical relief.

Lurgan Union, Northern Ireland.

At a recent meeting of the Lurgan Board of Guardians a letter was read from the Northern Ireland Ministry with regard to the guardians' proposal to increase the salary of Dr. May, senior visiting physician to the infirmary, from £185 to £350 per year, stating that, in view of the impending conversion of the Lurgan workhouse into a district hospital, it was an unsuitable time to make any permanent alterations in the salaries of the officers connected with the workhouse. There was justification, however, for sanctioning a bonus to Dr. May of £65 from November 1st. The guardians accepted this decision.

Correspondence.

THE HARVEY MEMORIAL TOWER.

SIR,—As one who brought the subject of the ruined tower of Hempstead Church to the notice of the Royal College of Physicians some five years ago, I beg to thank you for the account and illustrations in your issue of December 7th (p. 1072), which faithfully depict the desolation; and as an old member I wish to support the suggestion of Dr. Grabham that the British Medical Association should take a part in raising funds for the rebuilding. Mr. Hope Grant, temporarily suppressing a generous impulse, made the same suggestion in 1925,[1] but nothing came of it then. Dr. H. Reynolds Brown[2] collected 5s. from each of his colleagues practising at Maldon, Essex, and sent the sum to the treasurer; I suggest that his method is worthy of extensive imitation.

The reconstituted committee purpose to appoint local secretaries to collect funds. I have been appointed local secretary for University College Hospital, and I am happy to report that I have already collected from nearly every member (and hope finally from *every* member) of the staff of the hospital a contribution amounting in all to over £90. Personal application is the effective means of getting contributions. I have been agreeably surprised at the readiness with which the medical purse is opened on personal application on behalf of a noble cause. Half a crown from *every member of the profession*, a crown from half the members, will give us the sum required. The fund increases slowly; it has been *even suggested* by defeatists that it be closed. No, Sir, when we are hard driven we attack, we shell out. I ask members of the Association to bombard the honorary secretary, Dr. Arnold Stott, 58, Harley Street, W., with their five-shilling pieces. Your broadside, Sir, like Captain Harvey's at Trafalgar, will help us to victory.—I am, etc.,

London, Dec 8th HERBERT R. SPENCER.

THE BEGINNING OF THYROID THERAPY.

SIR,—A case of pronounced and typical *myxoedema*, which I treated by finely minced fresh thyroid gland made up in a sandwich was one of the first to be treated by oral administration of this gland. The treatment began on October 22nd, 1892; eighteen days later all the features and symptoms of myxoedema had disappeared, and were replaced by hyperthyroidism, with a pulse rate about 130. Fortunately one soon recognized that the seemingly innocent bits of raw gland were potent, and abatement of treatment had only a fortunate result. *Subsequently*, with the help of thyroid gland therapy, the patient lived in good health for many years, dying about six years ago from other causes. This was probably the record in *rapid "cure"* of myxoedema, and one not to be repeated. At that time it was necessary to go personally to the butchers and remove the glands from the sheep immediately after slaughter. Shortly after this *an extract for injection* was prepared from these glands by Mr. Kilner, the dispenser to the Bristol Royal Infirmary, as stated in my article in the *Medical Annual*, 1892 (p. 399), where my case is recorded.

Professor George Murray's letter in your issue of November 30th (p. 1030) recalls his case of myxoedema recorded in the *British Medical Journal* on October 10th, 1891; his was the first case to be treated by injections of the extract of the fresh gland. But neither Professor Murray's case nor my own represents the beginnings of thyroid therapy. We must give credit to Victor Horsley for suggesting the transplantation of a portion of the thyroid gland of a *sheep into the peritoneal cavity*, and to M. Lannelongue, who carried this suggestion into practice (*Le Progrès Méd.*, 1890, p. 209, cited by me in the *Medical Annual*, 1891, p. 333); *shortly afterwards* other cases were recorded by E. Hurry Fenwick and others. Hence the essential interest in Professor Murray's and my own cases lay in the administration of gland extract or tissue as an alternative to transplantation.

It may not be out of place to state that a little later,[1] in the hope of affording a diabetic patient the benefit of the internal secretion of the "islets"—that is, "insulin" as we know it to-day—I tried transplanting fresh removed pancreas, because, unlike what had happened in myxoedema, feeding with the corresponding raw gland had conferred no benefit on such cases. The surgeon, Mr. Harsant, took every precaution to ensure success, but the grafting process failed. Nowadays, when insulin and thyroid gland therapy have become general knowledge, the difficulties of earlier days are soon forgotten, but they are not without some historic interest.—I *am*, etc.,

Clifton, Bristol, Dec 3rd. PATRICK WATSON-WILLIAMS.

THE GLUCOSE TREATMENT OF ASTHMA.

SIR,—It is with diffidence that I write on the big subject of asthma; but to prevent enthusiasts being disappointed by a recently formulated line of treatment, *I should like to* indicate a simple clinical test which will enable the observer to select the cases suitable for the treatment of asthma with glucose.

In the correspondence columns of the *British Medical Journal* on January 31st, 1925 (p. 240), I gave, in a communication entitled "Acidosis and acetonaemia in relation to sea-sickness," a simple test for acetonuria, indicated the association of acidosis with intractable cases of sea-sickness, air-sickness, cyclic vomiting, and car-sickness, and concluded with a brief for the treatment of these conditions with glucose. The test is performed with one drop of urine saturated with a crystal of common washing soda on *a piece of notepaper, and a capillary tube containing* powdered sodium nitro-prusside and ammonium chloride (put up by Fletcher and Fletcher of Holloway, N.). The saturated drop of urine runs up the tube by capillary attraction, and if acetone bodies are present the reagent soon becomes amethyst and then petunia in colour; if acetone is absent the straw colour persists. This test does not appear to have any fallacies, and is a simple bedside procedure, avoiding the necessity of having urines sent to the surgery for examination, and the extra work involved in performing clinical tests after the long daily round of common tasks.

When at sea with the Eastern Mediterranean Squadron in 1917, I noticed that a number of previously intractable cases of sea-sickness were associated with acetonuria, and that some of the ratings concerned gave a positive test for acetone before putting to sea. These *patients* were definitely improved by large doses of glucose, and expressed "wonderful relief" when the urine became acetone-free.

A routine bedside examination for positive *acetonuria* in the case of all asthmatic patients will help the observer to pick out those who are suitable for *treatment with* glucose. The performance of this bedside test among all *my patients for the past ten years* has revealed acetonuria in many unsuspected places, but for the most part, excluding cases of tonsillitis, pneumonia, and acute fevers, where it is always present, *inborn errors of metabolism and* nervous control, associated with cyclic vomiting, car-sickness, migraine, asthma, and acute gout, stand out prominently. Massive doses of glucose appear to relieve these conditions and render the urine acetone-free, as *demonstrated* by the capillary tube, which has at first a petunia colour, becoming amethyst, and finally straw-coloured, in a series of tests at intervals of several hours. Since 1915, when I first noted the association of *acetonuria with air-*

[1] *British Medical Journal*, 1925, i, p. 905.
[2] Ibid., 1925, i, p. 1061.

[1] *British Medical Journal*, 1894.

sickness and migraine, and subsequently the relief of these and allied conditions by administering glucose, the problem has afforded me an interesting subject for investigation.

In conclusion, I wish to disclaim any originality in the practice of this line of treatment.—I am, etc.,

Midhurst, Sussex, Dec. 2nd. MARSTADUKE FAWKES.

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

SIR,—With reference to the letter which appeared in the *Journal* of November 23rd (p. 983) from Dr. Webster regarding our fluorescein treatment, I may mention that when Dr. Webster's first letter was published on August 24th (p. 367) I doubted whether to answer it. With all the material available at the Middlesex Hospital he apparently had not put the matter to the practical test before launching his criticism, which, however helpful it might be theoretically, does not seem a convincing way of proving his case. A hint was given in Dr. Copeman's letter of November 16th (p. 929), and now we have the confession that Dr. Webster did treat one case for Mr. C. H. S. Webb, which I happen to know was a deep-seated growth; for this type of case we do not claim any better result, though certainly no worse, than that which has followed the use of the old method of so-called "deep therapy."

As regards his criticism of my dosage, I am really amazed—the proper way of measuring a dose is the erythema dose on the skin, which is 1 Sabouraud B. I have found after years of treatment, whether with fluorescein or without, that it is quite easy to give three three-quarter doses in three weeks without any harmful effects, providing a sufficient interval is allowed for the skin to recover. Dr. Webster is quite right in stating that this means a 5-pastille dose at half distance, or even a 6½-pastille dose at one-third distance; but what has this to do with the matter? The skin is not suspended in the air away from the body. All we are claiming at present is better results on superficial cancers of a certain type—namely, breast carcinomata—than has hitherto been possible. When Dr. Webster has repeated our original experiment and has used our technique over any ordinary breast case, I shall pay attention to his conclusions. The really interesting point is that our claims can be decided, and I hope they will be, by any hospital, large or small, possessing any ordinary up-to-date *x*-ray installation; it is not necessary to employ special expensive machinery, such as that used by Dr. Webster and others in the so-called "deep therapy" (modified Erlanger treatment), which unfortunately has not proved quite so successful as we all had hoped it would be. Until, therefore, Dr. Webster reports that he has had failures in the type of case already stated, and has also closely followed our technique, there does not seem any use in continuing this correspondence.—I am, etc.,

CLAUDE GOULDSBROUGH,

November 29th Senior Radiologist, Royal Northern Hospital

REVOCABLE STERILIZATION OF THE FEMALE.

SIR,—In his letter (November 30th, p. 1031) Dr. G. L. Johnson asserts that temporary sterilization of the female may be obtained by dislocating the fimbriated ends of the Fallopian tubes, and tying them out of the way so that the ova drop harmlessly into the peritoneal cavity. It is difficult to see how this view can be maintained in face of the fact that there are many cases on record where an ovary has been removed on one side of the body and a Fallopian tube removed on the *other* side, and yet the ovum from one side of the body has found its way across the abdominal cavity to the opposite Fallopian tube and has become fertilized. This fact would seem to dispose of the supposition that keeping the fimbriated ends of the tubes away from the ovaries is sufficient to ensure sterility.

The method described by Grafenberg for use in cases where the medical attendant has decided that temporary sterilization is indicated, is much simpler and more efficient. A flexible ring of coiled silver wire (diameter 2–3 cm.) is introduced into the uterine cavity so that it lies wholly above the internal os. It is usually removed, and if necessary replaced, after a year. After its removal the woman is just as liable to conceive as if the ring had never been used. This apparatus, which is really intra-uterine, is not to be confused with the many so-called intrauterine (really intracervical) pessaries, which keep open a path from the septic vagina to the non-septic uterus, and are therefore dangerous.

A Russian observer, Retschnensky, believes that the silver ring alters the hydrogen-ion concentration in the uterus and so acts as a spermaticide; others suggest that it brings about infertility through changing the surface tension in the uterus. Gräfenberg points out that, even if the ovum were fertilized, embedding could not occur, since the ring sets up a *non-inflammatory* hypertrophy of the mucous membrane, which renders it incapable of acting as a nidus.

Gräfenberg has inserted the ring in 1,100 cases during the last ten years, and has watched many of the patients regularly during the whole of that time, without seeing a case of failure. His experience is corroborated by many other German and Russian investigators. My own knowledge is limited to 100 cases, but so far I have seen no reason to doubt that this method gives complete immunity against impregnation.

The insertion and removal of the ring calls for no greater skill than does the simple operation of curettage. An anaesthetic is seldom necessary, for very little dilatation usually suffices for the insertion of the ring, which is compressed in a special introducing instrument. The procedure appears to be harmless in the absence of genital infection, provided it is carried out with strict aseptic precautions. The absence of harmful irritative effects is apparently due to the fact that the uterine mucosa (unlike other mucous membranes) is cast off at each menstrual period. The value of the method lies in the fact that its reliability depends on the skill of the medical attendant, and not (as in most other contraceptives) on the skill or care of the patient.—I am, etc.,

London, W.1, Nov. 30th. NORMAN HAIRE.

TREATMENT OF GASTRIC AND DUODENAL ULCER.

SIR,—Apropos a letter appearing in the *Journal* of November 23rd (p. 984) from Dr. Wood Locket discussing the use of the duodenal tube in the treatment of chronic gastric ulcer, I should like to make a few remarks. I have only employed this procedure once, and I experienced the same gratifying result. Dr. Ernest Young (*Practitioner*, April, 1928) called my attention to the method, which he states is employed frequently in America and seldom in this country. Now it seems to me that patients here will not stand for it; some will co-operate for a few days, and then refuse to continue. I would like to hear from Dr. Locket if he finds any difficulty in getting his patients to retain the tube for fourteen to eighteen days. The method was introduced some ten years ago by Max Einhorn of America and taken up there with great enthusiasm.—I am, etc.,

Dublin, Dec 3rd. FRANCIS KENNEDY CAHILL, F.R.C.S.

INJECTION TREATMENT OF VARICOSE VEINS.

SIR,—I have found much of interest in Mr. G. H. Colt's article in the *Journal* of November 9th (p. 848), which deals with the salicylate effect very fully. I should like to confirm the author's findings. I, too, have found that the area of vein in which the pain is felt is the area that will become sclerosed, and in those cases where no pain has been felt there has been no subsequent sclerosis.

In spite of the excellent results given by the salicylate and salt solution I feel that it is not ideal. With the greatest care leakage does occasionally occur, and even a trace gives rise to annoying blistering at the site of injection. It seems much more toxic to the tissues than neosalvarsan.

Application of elastic pressure reduces the size of the thrombus, and I find that in cases in which the vein is clearly marked a roll of gauze stuck over the course of the vessel with mastisol under the elastic webbing gives a

greater proportion of "stiction" effects. This seems the ideal method of cure, as a large thrombus takes a long time to fibrose.—I am, etc.,

W. L. HECTOR, M.B., Ch.B.,
Surgeon, Letchworth Hospital.

Letchworth, Herts, Dec. 1st.

ROYAL MEDICAL BENEVOLENT FUND.

SIR,—I read in your issue of November 23rd (p. 981) the letter from Sir Thomas Barlow, president of the Royal Medical Benevolent Fund, asking for subscriptions for Christmas gifts to the annuitants and some of the grantees of the fund. My interest has lately been re-aroused, in that I have written personally to a number of my old Guy's friends asking them to become subscribers to the fund, and I have been struck by the want of knowledge of its existence, on the part of many, although on learning of it several have at once most generously subscribed.

Last year 485 grants were made. The needs of the applicants are often pathetic in the extreme: doctors who, through illness or old age, are no longer able to carry on, or who have met with misfortune, such as some seem never able to avoid; widows of others left penniless, and perhaps with children to educate; daughters unable to support themselves; and so the tale goes on from day to day and year to year. Yet although the fund does much good as it is, how miserably small are the grants the committee can make! £36 as the maximum annual grant to a destitute and penniless widow; an annuity of £42 to a doctor, aged 76 years, whose eyesight was damaged by *x* rays in the early days of long exposures and insufficient protection, with the result that at his age he is quite unable to work; and many similarly sad cases. Terribly inadequate help, is it not? But the committee can do no more without ampler aid from the members of the profession. Despite their conviction that the profession should be responsible for its own casualties, at present only some 4,000 to 5,000 out of 50,000 or more doctors subscribe!

Now doctors are certainly not an ungenerous body of men, and my belief is that the insufficient support accorded is in the main due to ignorance of the fund, and to the busy yet often so unbusinesslike life which doctors lead, leaving little or no time to interest themselves in matters outside their daily round. If we could get but 30,000 out of the 50,000 doctors to subscribe one guinea annually, how much more could the committee do to provide help and comfort really commensurate with the needs, but which at present, owing to lack of funds, it is impotent to do.

I hope there may be many who, as one of their Christmas gifts, will become contributors to the fund, and that Sir Thomas Barlow's letter may so appeal to them that they will not only join themselves, but urge others to do likewise, and thereby bring about such an addition to our resources as to provide both for this Christmas and for the years to come—an object which will be best achieved by an increase in our list of annual subscribers.—I am, etc.,

JOHN FAWCETT,
A Vice-President of the Fund.

London, W.1, Dec. 3rd.

SIR,—I beg to acknowledge the receipt of £43 up to the end of November for Christmas gifts, in response to Sir Thomas Barlow's appeal, which was published in your issue of November 23rd. These donations have been received from twenty-three members of the profession. The amount of money required for Christmas gifts is £500, so that further donations are very urgently needed, and should be sent to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, W.1.—I am, etc.,

E. C. PENNEFATHER,
Secretary.

December 3rd.

THE MEDICAL AND DENTISTS REGISTERS.

SIR,—In order to facilitate the work of those who find it essential to know whether a medical practitioner is legally qualified or not—such, for instance, as officials of insurance committees, chemists, and druggists—the General Medical Council is continuing to publish an Office Edition of the *Medical Register*. This edition is bound in paper boards and contains all names and addresses as they appear in the Official Edition, but is printed on cheaper paper and without the preliminary matter. The Office Edition is published at the special rate of 7s. 6d. post free, but no copies can be issued at this price unless they are ordered and paid for prior to December 31st of the year preceding that of publication; order forms will be sent on request.

The Council also issues each month lists of new registrations and names deleted from the *Register*. These are issued on a written understanding that the lists are for the personal use of the firm to which they are supplied, that they are not communicated to any other person, and that they are not sent out from the office in order to have stencils made. Every possible care is taken to protect subscribers from the lists being made use of by others. I might add that these lists are for obvious reasons not supplied to any addressing agency: the Council has no business arrangement or agreement of any kind with any addressing agency for supplying to them any official information, and it certainly has no exclusive arrangement of this kind.

Similarly the Dental Board of the United Kingdom issues an Office Edition of the *Dentists Register*, which includes the names of all registered dentists, together with a local list. The price of this is 4s. post free, provided copies are ordered and paid for prior to December 31st of the year preceding that of publication. Monthly lists of new registrations and deletions are also issued by the Board.

I might add that the General Medical Council and the Dental Board are always glad to answer inquiries as to whether practitioners are registered or not. Preferably these should be in writing to prevent misunderstanding, but inquiries by telephone are replied to at once.—I am, etc.,

NORMAN C. KING,
Registrar, General Medical Council.

44, Hallam Street, Portland Place, W.1, Dec. 4th.

LOCAL GOVERNMENT ACT, 1929.

SIR,—On behalf of the councils of the Poor Law Medical Officers' Association and the Public Vaccinators' Association, I am desired to appeal, through your columns, to all public vaccinators and Poor Law medical officers who are also members of the local authorities to which they will be transferred on April 1st next to communicate with me at once, if they have not already done so, giving such particulars as may be useful in framing representations to the central authority in their behalf.—I am, etc.,

ALBERT ERNEST COPE, M.D.,
President, Public Vaccinators' Association; Secretary, Poor Law Medical Officers' Association.

65, Belgrave Road, Westminster, S.W.1, Dec. 7th.

Obituary.

THOMAS FINLAYSON DEWAR, C.B., M.D., D.Sc.,

Medical Inspector, Local Government Board for Scotland.

THE death took place, on November 27th, at his residence in Edinburgh, of Dr. T. F. Dewar, who was a member of the staff of the Department of Health for Scotland. Dr. Dewar had been in failing health for some time, but his death was unexpected.

Thomas Finlayson Dewar, whose father was a medical practitioner in Arbroath, was born there in 1866, and was educated at the Arbroath High School, afterwards going to Aberdeen to study medicine. He graduated M.B., C.M. in 1887, and proceeded M.D. with honours in 1890. Taking up the study of public health at once, he went to Edinburgh, where he graduated B.Sc. in 1888, and took the degree of D.Sc. (Public Health) in 1906. His thesis for the latter degree dealt with the subject of the sanitation of armies in the field, and to a large extent embodied the experiences which he had gained in the South African war. After graduation in public health, Dr. Dewar took up general practice in Arbroath, where he became a member of the town council and of the school board. In 1895 he was appointed medical officer of health for the burgh of Monifieth, subsequently for the county of Forfar, and later still for the counties of Fife and Kinross. He had served in South Africa during the war of 1899–1902, first as a combatant in the Imperial Yeomanry, and afterwards as a surgeon captain; he received the Queen's medal with four clasps. In 1909, when school medical inspection began in Scotland, he undertook the organization of this part of

public health work in the counties of Fife and Kinross, and was appointed chief medical inspector of these counties. In the following year he became medical inspector under the Local Government Board for Scotland, and he continued to serve in this capacity (apart from the time in which he was engaged in military duty) until the absorption of the Local Government Board into the Scottish Board of Health in 1919.

During the recent war he had a distinguished military service, commencing as D.A.D.M.S. of the 51st (Highland) Division, and later A.D.M.S. Northern Army, with the charge generally of the medical arrangements made in prospect of an attempted invasion of East Anglia. At a later period, when the danger of invasion became less acute, he was transferred to be A.D.M.S. of the 57th (West Lancs) Division, with which he served in France. His total service in France with the 51st and 57th Divisions amounted to three years, during which time both of these Divisions saw much fighting, and he took part in many of the battles of the British armies in France in 1917 and 1918. For his services he was four times mentioned in dispatches, and was created a Companion of the Bath (Military Division) in the New Year's honours list of 1918. On his return to civil life from military service Dr. Dewar became a medical officer of the Scottish Board of Health when this body absorbed the Local Government Board in 1919, and he later became an officer of the Scottish Department of Health when this took over the work of the Board in 1929.

In addition to the administrative duties of his post in the Board of Health, Dr. Dewar engaged in many other pursuits. Thus he was medical adviser to the Scottish headquarters of the Boy Scouts' Association, and a member of council of the Institute of Public Health, and of the Society of Medical Officers of Health. From 1919 to 1922 he was an examiner for the degrees of M.B. and M.D. and for the public health diploma in the University of Aberdeen. His duties and his widely recognized abilities made it natural for him to be a member of various committees of inquiry. Thus he issued a report to the Local Government Board, in association with Drs. Dittmar and McVail, on "The administrative control of pulmonary phthisis in Glasgow" in 1911, and he was a member of the Departmental Committee (Lord Salvesen's) on Puerperal Morbidity and Mortality in 1923-24. Other reports by him included one upon ophthalmia neonatorum in Scotland; another, upon the housing of workers at Rosyth and of miners in Fifeshire, was a valuable contribution to a subject of great social interest after the war; another dealt with an outbreak of enteric fever in Ayrshire; and in 1923 he contributed an article to the *Edinburgh Medical Journal* upon "The incidence of venereal disease in Scotland." Various other publications by him included *Essays on the Natural History of Arbroath and District*, 1893, *With the Scottish Yeomanry*, 1901, and the well-known *Medical Vignettes*, 1928, which was a series of amusing sketches of medical practice drawn mainly from his South African experiences. He was for very many years a member of the British Medical Association.

Dr. Dewar was unmarried. In private life he was precise and business-like, a kind friend, and an agreeable companion. His sage and kindly counsel was constantly sought by his professional colleagues, both in personal matters and in the many public affairs where changes have recently been taking place in medical practice, and it was always given with unfailing generosity. His loss, both as a friend and a counsellor, will be keenly felt by a large circle. He was buried in Arbroath on November 30th.

We are indebted to Dr. C. E. DOUGLAS (St. Andrews) for the following appreciation:

In the person of Dr. Dewar one of the most interesting and engaging personalities in the Association has passed away. Qualifying in medicine before he was of age to graduate, the eager spirit we learnt to know soon showed itself, and he was off to Edinburgh to study and graduate in public health, taking the B.Sc. in 1888. After serving a useful term of work in general practice under his gifted father, the late Dr. James Dewar, he began his career as a health officer in the burgh of Monifieth; thence via Forfarshire and Fife to the centre of things for him henceforth—the Board of Health in Edinburgh. But official life was far from absorbing all his energies. The Boer war arrived, and Dewar was out in it as a trooper of the Fife and Forfar Yeomanry, serving for nine months in the ranks and sharing in the wild excitements of the pursuit of De Wet. But medical men were too precious for this to be permitted, and Dewar was soon in his rightful position as a medical officer, coming out of that affair with the Queen's medal and four clasps. His native town, in which he had done good service as a town councillor and as a member of the school board, gave him the freedom of the burgh on his return from South Africa. It is significant that his experiences out there were used by him for a thesis, in 1906, for the D.Sc. of Edinburgh, on the sanitation of armies in the field. In 1910 he became a medical inspector of the Local Government Board of Scotland, which appointment he held until his death. In the late war another opening for his abilities came, and he was appointed A.D.M.S. of the 51st (Highland) Division. From Festubert onwards he occupied positions of great responsibility; for the first three years on the French front, and as A.D.M.S. Northern Army in East Anglia and A.D.M.S. 57th Division, he did great work in organizing and maintaining the medical and sanitary efficiency of these bodies, receiving from the King in person the Star of the Companion of the Bath (Military Division). Such are some of his official and military records. He was a voluminous writer on many subjects, contributing reports on pulmonary phthisis in Glasgow and on ophthalmia neonatorum in Scotland; delightful essays on the natural history of his native district; and medical vignettes of scenes, mainly in his two campaigns. These, together with much sound work on Lord Salvesen's Departmental Committee on Puerperal Morbidity and Mortality, examining in medicine and public health for Aberdeen University, medical advising of the Scottish boy scout headquarters, and similar activities, made up a busy life.

But none of these doings showed Dewar as he was as a man. Officialdom sat lightly upon him; upon no man less. Methodical he was to a degree; but he could and did unbend, and to all his many and varied friends of all sorts and ranks he was a true friend and one singularly beloved. Of his kindnesses he would not have us speak. Let one little instance suffice, of one charity which helps the very hopeless in their homes. After the war he wrote to the lady to whom he sent his subscription that as things were he would now subscribe double; at his death a legacy equal to ten years' subscription was left to this charity. Such was a characteristic deed on the part of one who will long be remembered as a straight man, a strong man, and one who died as he would have wished, in harness, without a word of complaint against the fate which laid upon him years of suffering borne with stoic fortitude.

THE HON. SIR JOHN ALEXANDER COCKBURN, K.C.M.G., M.D.,

Formerly Premier of South Australia.

SIR JOHN COCKBURN, who died on November 26th, was so largely immersed during the early part of his life in Australian politics, and during the later part in various sociological interests, that he was scarcely remembered as a medical man. He qualified as far back as 1871, graduating M.D. of London University, with the Gold Medal, in 1874, and obtaining the M.D.Adelaide in 1877.

Born in the Border country just upon eighty years ago, John Cockburn, after completing his professional studies at King's College, London, migrated to Australia in 1875, and became medical officer of health for Jamestown, a small town in South Australia. He very soon interested himself in local affairs, and became mayor within a year or two of his settlement there. A few years later he was elected to the State Parliament, and with remarkable rapidity rose in the councils until at 38 he had become Premier of his State, the youngest Premier ever known in Australia. This office he held for about fourteen months, and later, after a period of retirement, he held various portfolios, presently, however, resigning Australian politics to become Agent-General in London.

To very many people he will be best remembered as the president of the Child Study Society. He was almost always present at the meetings of that body and at conferences in which it took part, and his old-world picturesqueness, as well as great personal charm and dignity of manner, marked him out in any gathering of men. His genial contributions to discussion were always well worth hearing. This was only one of many social and educational activities in which he interested himself. He was chairman of the Nature Study Association, a member of the council of King's College, London, a vice-president of the Royal Sanitary Institute, and a diligent representative at all kinds of health and social work conferences at home and abroad.

Although a man of strong intellect and versatility, Sir John Cockburn's contributions to literature were very slight and occasional. Apart from some articles in periodicals, mostly dealing with Australian affairs, they chiefly consisted in the part authorship of a nature reader for senior students. He had ceased medical practice for a generation, and took little or no part in professional activities.

EDITH SHOVE, M.B.Lond.

My old friend Miss Edith Shove, M.B., passed to her rest on November 16th, in her eighty-second year. Unlike most medical women, she was apprenticed in the arts of the surgeon and the apothecary for five years with Dr. Prior Purvis of Blackheath, who was himself a warm and consistent advocate of medical education for women. She was one of the first students of the London (Royal Free Hospital) School of Medicine for Women, and took a goodly number of prizes; she was also in the first group of women students to present itself for examination at the University of London, and passed the preliminary scientific in the first division in 1879. In 1881 she became a licentiate in medicine and in midwifery of Queen's College, Ireland, and up to the time of her graduation in 1882, when she obtained the M.B. degree of the University of London with honours in medicine, she was demonstrator in anatomy at the London School of Medicine for Women, where her thorough teaching was much appreciated. She was one of the first batch of women candidates for this degree, the others being Miss Helen Prideaux, Miss Tomlinson, and myself. Immediately after qualification she was appointed medical officer to the female employees of the Post Office, a position which she held with much satisfaction to everyone concerned until she retired under the age limit.

Edith Shove was never "a limelight child." I think more than any of us she exemplified the truth of the Bible statement, "in quietness and in confidence shall be your strength." She was a remarkably quiet, retiring, modest woman. Like most of us, she had some little personal peculiarities, one of which was a habit of talking aloud to herself as if seeking counsel from a friend. There is an amusing story told by one of her patients. The lady was amused to hear the low, soft voice of her new medical adviser saying: "No, I cannot think that it is drink. But what is it? Could it be drugs? I think not. Ah! now I have it: she is a high-grade mentally defective person." Also at times Edith Shove was apt to seek counsel from the patient herself, saying, for instance, "Yes, you evidently require some little assistance. I wonder which you would prefer. Shall it be rhubarb or senna?" Her interest was not confined to the ordinary everyday advising of sick folk. She was also a member of the Society for Psychical Research, the Hellenic Society, and the Society for Roman Studies. Before the war she travelled much abroad, visiting all parts of Europe and Egypt; in fact, she was a well-educated, good all-round practitioner, and something of an author too, for although her official position precluded her from publishing such studies, she helped the Post Office by writing on such matters as telegraphist's cramp and other ailments specially connected with the work of the women employees.

And now in the fullness of time she has passed to her rest, but the fragrance of her memory still survives in some grateful hearts.

MARY SCHARLIEB.

Dr. PAULIN MARTIN, who died on November 8th, was born at Highworth, Wiltshire, in 1842, the son of Dr. John Martin, who went to Abingdon, Berkshire, to practise in 1847. Paulin Martin was educated at Radley College, and entered St. Bartholomew's Hospital in 1858, where his midwifery tutor was Dr. Robert Greenhalgh; he learnt his medicine from Dr. R. Martin, F.R.C.P., and his surgery from Sir William Lawrence. At the death of his father in 1864, Paulin Martin took over the Abingdon practice, which he worked single-handed for forty-five years, when his eldest son joined him, and together they carried on the large country practice until his son's death in 1926. In 1874 he married Mary, daughter of Dr. A. Iles of Fairford, Gloucestershire. A correspondent (H. E. B.) writes: Dr. Martin's profession absorbed him and left little time for leisure, but what time could be spared was devoted to literature and geology. While at Radley he started his now famous collection of old books, a hobby which he never dropped; he specialized in Shakespeare, early printed books, and Bibles. Rare books could be bought without great expense in those days, and the rarest and best were not out of reach if one knew, as Dr. Martin did, what were the best. He searched and bought carefully and assiduously, and entirely without thought of any future monetary profit. Apart from the regret, softened by his age and failing memory, of selling some of his library his chief emotion seemed to be surprise that the folios he had bought for a hundred pounds or so should be eagerly bought for five thousand. The gap in the book-shelves seemed at once to be filled by editions only a little less rare, and now at his death there are scores of treasures which show the skill and care of a great collector. Nothing gave him greater pleasure than thrusting a first folio or a first *Compleat Angler* into the hands of anyone who showed the least interest in them. He was delighted when Lord and Lady Oxford, who came to consult him when he was 80, recognized his first folio from the date on the binding. He formed a collection of fossils and antiquities from the neighbourhood of Abingdon, which was an early Neolithic settlement; the doors of his house were propped open in summer with cannon balls from the civil war, and an ancient tilting helmet shared the wall of his study with portraits of Shakespeare and Chaucer. His practice extended for many miles round Abingdon. He generally drove himself, his round often being between thirty and forty miles over stony roads in a dog-cart, or in very bad weather in a brougham. He did his own dispensing, often having fifty bottles of medicine to make up at the end of the round. He did a great deal of midwifery—seventy or eighty cases in the year, mostly at a guinea a case—though later (in 1880) he gave up the guinea ones and charged two guineas. A human touch comes in one of his letters, "There is nothing so worrying as having a message from a grinning, ignorant ass of a husband asking one to 'keep in the way'—destroying all sleep and comfort." A good sample of an ordinary day in the eighties was one of visits to thirteen villages in the neighbourhood, besides those in Abingdon, entailing a round of thirty-seven miles—not too long in these days of motors and good roads, but in those days of stony unrolled ways with iron-bound wheels even a pair of horses could not make the journey anything but slow and tiring. Between his journeys he dispensed the usual "endless bottles of physic," and finished the day at 10 p.m. with a guinea midwifery case—and so to bed with no more than a fleeting glance at his beloved folios.

Dr. JAMES GILLON ROSS, medical officer of health for Whitby Urban District Council, died on November 29th, in his sixtieth year. He received his medical education in Edinburgh, where he graduated M.B., C.M. in 1898, being awarded the silver medal in pathology. After holding the post of house-surgeon to Nottingham General Dispensary, he served for two years in the West African Frontier Force. In 1902 he became an assistant to the late Dr. John Wilson in Whitby, and subsequently joined in partnership for a short time Dr. Wilson's son, after whose death he continued the practice alone. He was later appointed medical officer of health for Whitby, medical officer to the Post Office,

surgeon to Whitby Cottage Hospital and also to the police force, and local referee to the Ministry of Pensions. He took an active interest in the work of the British Red Cross Society, of which he was an honorary life member. During the war he held a commission in the Royal Army Medical Corps. He was a member of the British Medical Association, and was president this year of the Whitby Rotary Club.

Dr. GEOFFREY LUCAS, who died at Las Palmas on November 26th, after a long illness, was born in 1875, and received his medical education at Cambridge and St. George's Hospital. He obtained the diploma L.S.A. in 1903, and graduated M.D.Durh. in 1919. After holding the appointments of assistant and senior house-physician at the Westminster Hospital he served with the Orient Steam Navigation Company from 1904 to 1906. He then started to practise in Ringwood, became medical officer of health there, and developed an interest in tuberculosis, which led him to being associated as physician with the Nordrach Sanatorium, Banchory, from 1909 to 1921, with the exception of the war period. From 1916 to 1917 he was physician to the first Scottish General Hospital, and subsequently consulting physician for diseases of the chest to the North-East Scottish Command. He was assistant to the professor of medicine at the University of Aberdeen in 1917–18, and, holding a commission in the R.A.M.C., was for a time at No. 11 Stationary Hospital, B.E.F. From 1921 to 1928 he was resident physician to Mundesley Sanatorium. Dr. Lucas was a member of the British Medical Association and a fellow of the Royal Society of Medicine; he contributed articles on pulmonary conditions and associated subjects to the *British Medical Journal* and the *Journal of Tuberculosis*. A colleague writes: Dr. Geoffrey Lucas spent many years of his life as sanatorium medical officer; he was very popular with the patients, who used to confide their troubles to him and regard him as a confidential friend as well as a doctor. Lucas had a remarkable knowledge of human nature and the gift of combining discipline with human understanding, so that his patients had the greatest faith in him, knowing that he had their interests at heart and that no detail in their lives was too small for his sympathetic consideration. Apart from his work Lucas was a most sociable and popular man, who was fond of sport and games; he will be sadly missed by a large circle of friends. He leaves a widow and two children.

Medico-Legal.

PROSECUTION UNDER THE DANGEROUS DRUGS ACT.

An Unregistered Practitioner Convicted.

AT Maidenhead, on December 2nd, Richard William Starkie, a practitioner whose name had been removed from the *Medical Register* in 1922, pleaded guilty to summonses under the Dangerous Drugs Act alleging that he offered to supply heroin to two persons (a man and a woman) specified in the charge, and was sentenced to twelve months' imprisonment in the second division.

There were twelve summonses; the accused pleaded guilty to the first of them, which alleged that, though not duly authorized to do so, he offered to procure heroin for the man and woman; he pleaded guilty also to other charges of offering to procure, and procuring, heroin, and of aiding and abetting; but to three charges of aiding and abetting the manager of a firm of chemists to supply the heroin he pleaded not guilty.

Mr. Sefton Cohen, for the prosecution, stated that on the facts of the case there was no defence in law. The prescriptions were handed to the chemist by Geoffrey Bradford Vilmer, who called himself Major Melville, and were signed "R. Starkie" with letters the chemist took to be M.D. The chemist not only inquired about the identity of R. Starkie, but took the precaution of telephoning Mr. Starkie and, later, of writing to him. In reply, Mr. Starkie intimated that it was "O.K." Starkie's name had been removed from the *Medical Register*, and the only qualification he now possessed was that of Licentiate of Midwifery in Dublin. It appeared that he had been in the habit of signing blank sheets of paper and giving them to Vilmer, who, he knew, was going to fill in the prescriptions and make them out for whatever amount he felt inclined to order. The patient named on each prescription was Mrs. Melville, but for the prosecution it was stated that this patient did not receive all the heroin mentioned in the prescriptions, part of it being taken by Vilmer himself. It was only fair to state that the person calling herself Mrs. Melville had had serious internal operations, which might have afforded her some reason for taking a narcotic drug. Starkie's explanation, as embodied in a letter which he had sent to the police, was that he had been tricked by Vilmer, believing that Vilmer had obtained permission from Scotland Yard for him to break the provisions of the Dangerous Drugs Acts. No such permission was given, or could have been given, and it was inconceivable that a person of Starkie's age and knowledge of affairs could believe such a fantastic story. From July 8th to October 14th twenty-eight prescriptions—purporting to be signed by Starkie, though he objected to some of the signatures—had been dispensed, and the total amount of heroin obtained was 2,150 tablets, containing in all 358 grains, which worked out at about 3 grains a day.

Chief Inspector Prothero said that Starkie was at one time a police surgeon, and was well known to Scotland Yard. Before he lost his qualifications he practised at Oakley Square, and was still practising there. For the defence Mr. Caswell asked the magistrate to believe that Starkie was working hard to rehabilitate himself, and was not knowingly issuing prescriptions for dangerous drugs without authority. He had given the prescriptions in good faith.

Mr. Starkie has given notice of his intention to appeal to Quarter Sessions against his sentence.

OSTEOPATH CENSURED BY CORONER'S JURY.

ON November 23th a coroner's jury at Southend censured an osteopath, Mr. A. L. Winer, for the manner in which he had treated a patient, aged 72, whose death was due to acute pneumonia and accelerated by insufficient food.

The patient, who had undergone an eight months' course of dietetic and manipulative treatment prescribed by Mr. Winer, died on November 9th. In evidence, it was stated that he had had a rupture four years previously, and, after refusing the advice of four doctors, who had recommended a truss, he followed Mr. Winer's treatment. In July he had complained that he was making no progress, and that he felt depressed, but was told by the osteopath that he must keep more cheerful and help himself. The deceased had refused to have any medical man to upset Mr. Winer's cure, which had been guaranteed.

Sir Bernard Spilsbury, who had performed a post-mortem examination, said that the body was emaciated, the flesh sunken, and the ribs prominent. Internally there was an almost complete absence of fat; acute pleurisy and pneumonia were present in the right lung. In reply to a question from the coroner, he said that there was no disease present which would account for the emaciation. The diet represented on the diet sheet would be quite inadequate to maintain the strength of any individual.

On behalf of Mr. Winer, it was stated that the osteopathic principle was to reduce the diet and let the body get rid of the poison which might be in it. Mr. Winer had treated hundreds of cases in Westcliff, and the deceased was the first who had died. Mr. Winer, in giving evidence, described himself as an osteopath and nature practitioner. The letters, O.D., O.D.C., M.B.A.O., after his name meant that he was a doctor of osteopathy, a doctor of chiropractic, and a member of the British Association of Osteopaths. The deceased, he said, had a normal appetite, but was continually over-eating.

After the jury had returned its verdict, the coroner said to Mr. Winer: "The jury have taken a merciful view, and you are fortunate. It must have been obvious to anyone, and especially to you, attending the deceased for weeks, that by your diet treatment he was slowly being starved. The jury's censure is deserved, and I hope that this censure and warning may have a good effect in the future."

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE chief work of the House of Commons this week has been consideration of amendments to the Unemployment Insurance Bill, in which the Government has had to make substantial alterations. The Highlands and Islands Bill was read a third time on December 9th. The Government hopes to adjourn the House for Christmas on December 20th, but the programme of business is congested.

In the House of Lords the committee stage of the Mental Treatment Bill was set down for December 10th. For the Government Earl Russell put down many drafting and technical amendments. Lord Danesfort tabled an amendment proposing that voluntary boarders should be accompanied by a medical certificate, to be signed by the usual medical attendant of the patient, or by a medical practitioner approved for the purpose by the Board of Control, or by the local authority of the area.

The meeting of the Parliamentary Medical Committee has been postponed till next week, when it is hoped to have an address upon the Mental Treatment Bill from Sir Hubert Bond. This will probably be on December 17th.

Silicosis.—Mr. CLYNES, replying to Mr. Hoffman on November 28th, said that it was estimated that the number of deaths from silicosis or silicosis accompanied by tuberculosis was 28 in 1923 and 35 in 1929. Compensation was paid in 1928 under the Refractories Industries Scheme in 12 cases, including 1 fatal case, and in 10 cases, including 3 fatal cases, in 1929. Under the Metal Grinding Scheme there were 12 cases, including 1 fatal, in 1928. Figures for 1929 were not available. Mr. CLYNES stated, on December 5th, that the risk of silicosis among quarrymen was by no means slight, and he could not allow local authorities employing them to contract out of the sandstone industry compensation fund.

Deaths from Diphtheria, Cancer, and Typhoid Fever in Scotland.—On December 2nd Mr. ADAMSON told Mr. Bromley that in Scotland there were, in nine months of 1929, 336 deaths from diphtheria, 5,224 from cancer, and 12 from typhoid fever. The figures for typhoid fever were exclusive of paratyphoid fever. There had been no deaths from small-pox for four years.

Undulant Fever.—Replying to Dr. Fremantle, Mr. GREENWOOD said, on November 28th, that undulant fever was not notifiable. Fourteen cases had been traced during the last five years in England and Wales. An inquiry into this disease had been made, and secured evidence that undulant fever in man had been closely related to cattle affected by contagious abortion. The whole subject was receiving attention in co-operation with the Medical Research Council and the Ministry of Agriculture and Fisheries.

Malaria in Bengal.—On December 2nd Mr. WEDGWOOD BENN informed Commander Bellairs that so far as he was aware there had been no increase in malaria in Bengal in recent years. He understood that Sir Malcolm Watson had suggested to the Ross Institute that an inquiry should be made as to whether the embankments of the Ganges Delta produced conditions favourable to malaria, and, if so, whether a remedy could be found. This matter was now engaging the attention of the Government of Bengal. He added that a chair of malariology would be established in the new Rockefeller Institute in Calcutta. Dr. FREMANTLE asked if it was not a fact that no policy had yet been formulated that would really remove malaria, and that the problem required much more inquiry. He suggested a joint inquiry between the British Government departments concerned with those of India and the colonies. Mr. BENN replied that this was a much wider question. He had stated what steps were being taken in India.

Schick Test and Diphtheria Immunization.—On December 3rd Miss LAWRENCE, replying to Mr. Freeman, said that local authorities did not "impose" the Schick test for diphtheria on school children. Parents were invited to have their children tested, and, if desired, immunized. The procedure was entirely voluntary. Local authorities were empowered to act for this purpose with the sanction of her department under Section 133 of the Public Health Act, 1875, or Section 77 of the Public Health (London) Act, 1891. Advice was given to parents by the local authority, but no instructions were issued. There was abundant evidence that the practice of active immunization, applied to persons who had been shown by the Schick test to be susceptible to diphtheria, protected such persons against the disease. The Minister had no information as to how many children were immunized in 1923 or of the cost of each operation.

Foot-and-Mouth Disease.—On December 9th Mr. BUXTON, replying to Mr. Matters, said that the experiments of the Foot-and-Mouth Disease Research Committee had shown that the virus of foot-and-mouth disease remained active in bone marrow which had been kept at a low temperature for seventy days. It was therefore theoretically possible for the disease to be introduced into this country in the marrow of the bones of chilled beef imported from the Argentine Republic, but there was no positive evidence that this had happened.

Accidents to Children in London Streets.—Mr. CLYNES told Mr. Ernest Evans, on December 2nd, that he was aware of, and deplored, the loss of life among children by street accidents in Greater London. The police did all in their power for the safety of children crossing the roads in the vicinity of schools. The Commissioner of Police was also considering the question of arranging a conference with representatives of the education authorities with a view to examining further the whole question.

Prophylactic Use of Artificial Sunlight.—Mr. GREENWOOD, replying to Dr. Forgan on November 28th, said the extension of facilities for the preventive administration of artificial sunlight to mothers and children was a matter for local authorities. He was not aware of any shortage of doctors with experience of this method of treatment.

Export of Dangerous Drugs.—Mr. CLYNES, replying to Sir Kenyon Vaughan-Morgan on November 28th, said the total exports of morphine alkaloid from the United Kingdom were 2,185 oz. in 1925, 455 in 1926, 265 in 1927, and 174 in 1928. The exports of morphine salts were 82,110 oz. in 1925, 63,433 in 1926, 58,138 in 1927, and 33,812 in 1928. The exports of morphine and its salts contained in preparations were 11,002 oz. in 1925, 9,401 in 1926, 7,701 in 1927, and 10,838 in 1928. In 1925 516 oz. of heroin alkaloid were exported, 273 in 1926, 519 in 1927, and 353 in 1928. In 1925 7,728 oz. of heroin salts were exported, 6,470 in 1926, 10,576 in 1927, and 5,582 in 1928. In 1925 the export of heroin and its salts contained in preparations amounted to 69 oz., 56 in 1926, 71 in 1927, and 103 in 1928. Information as to the value of these exports was not available.

Mental Defectives in Institutions.—Mr. GREENWOOD, in reply to Major Glyn on November 28th, said that the total number of mental defectives maintained in institutions or under guardianship at the joint charge of the local authorities and the Exchequer was 20,358 on January 1st, 1929. There were 19,606 under supervision. The cost to the local authorities for the year ended on March 31st, 1929, was £1,216,820. Of this expenditure £609,519 was borne by the Exchequer. In addition, a relatively small number of defectives was maintained in institutions or under guardianship at the sole charge of local authorities. Particulars of the number and cost were not available. The total cost to the Board of Control of such institutions directly under their administration during the year ended on March 31st, 1929, was £45,015, towards which £1,838 was contributed by local authorities or relatives of the patients. The number of defectives under treatment at these institutions on January 1st, 1929, was 785. Answering Mr. Sorensen, Mr. GREENWOOD said the statistics did not enable him to say how many young persons certified as mentally deficient and suitable for institutional treatment could not receive such treatment through lack of accommodation.

Mental Nurses and Registration.—Mr. GREENWOOD told Mr. Remer, on November 28th, that possession of the certificates of the Royal Medico-Psychological Association did not entitle mental nurses to admission to the register kept under the Nurses Registration Act. He thought the matter was capable of adjustment between the bodies concerned.

Licences for Certified Milk.—Mr. GREENWOOD told General Clifton Brown, on November 28th, that there was insufficient justification for a reduction of the fees of licences for certified Grade A tuberculin-tested milk. He would consider the matter in consultation with the Chancellor of the Exchequer when opportunity occurred for the general revision of the Special Designations Order. He would also consult the Minister of Agriculture.

Protection from Tuberculous Milk.—Dr. Somerville Hastings was told by Mr. GREENWOOD, on November 28th, that the steps taken to protect the public from tuberculous milk included the promotion of legislation and the issue of orders and circulars. While the actual responsibility for the protection of the public health rested with local authorities, his department assisted by inspection and advice both to local authorities and to milk producers.

Inspection of Dairy Farms.—Mr. GREENWOOD told Dr. Fremantle, on December 5th, that two inspectors were employed by the Ministry of Health in the inspection of dairy farms, but neither of them was a qualified veterinary surgeon. The only farms inspected by officers of the Ministry were those producing certified and Grade A (tuberculin-tested) milk. Examination and testing of cattle on these farms was, however, carried out by qualified veterinary surgeons approved by the department. Dr. FREMANTLE contended that, as the object of the inspection was to help farmers to eliminate tuberculosis, it would be a greater help to them if the inspectors from the Ministry were qualified veterinary inspectors. Mr. GREENWOOD said he would be glad to discuss the question with Dr. Fremantle.

Treatment of Wounded Ex-Service Men Temporarily Insane.—Mr. ROBERTS, replying to Colonel Moore on November 28th, said that he was not aware of recent cases of wounded ex-service men becoming temporarily insane, but where symptoms of the kind were manifested as the result of a war injury, treatment would be given or other appropriate action taken by the Ministry of Pensions.

Medical Treatment of Ex-Service Men.—Mr. ROBERTS, replying on December 9th to Sir G. Bowyer, who asked if he intended to take over all medical and surgical treatment of ex-service men, providing, where necessary, full-time medical officers for the purpose, said that his department had authority under the Royal Warrants to provide only such treatment as was not otherwise provided. He could not, therefore, adopt the course suggested without duplicating other statutory arrangements for the provision of treatment which were in operation under the National Health Insurance Acts and other enactments.

Tuberculous Ex-Service Men Unfit for Work.—Mr. ROBERTS, in reply to Mr. Kiuley on December 9th, said that he had no means of ascertaining the number of tuberculous ex-service men who, though certified as unfit for work, were not receiving treatment allowances. Such certification would ordinarily be done by practitioners acting under the National Health Insurance Acts. Mr. KINLEY asked if the Minister would consult with his medical officer on the necessity for putting this matter on a proper and just footing. Mr. ROBERTS replied that he would be very happy to give consideration to the point which had been raised. Dr. VERNON DAVIES asked if they were to understand that once an ex-service man got on the panel under the Ministry of Health, the Ministry lost all further interest in the case. Mr. ROBERTS: No, Sir.

Conditions of Service Life and Pulmonary Tuberculosis.—Answering on behalf of the three defence services, on December 5th, Mr. ADAMSON said the result of the report on the relationship between the conditions of service life and pulmonary tuberculosis had been that the medical authorities of the three Service Departments had taken additional measures to facilitate the prevention, detection, and treatment of pulmonary tuberculosis. It was hoped that these measures would facilitate the determination of attributability to conditions of service, but it was considered unlikely

that they would have any material effect on the present practice as regards pensions awards in the Army and Air Force, which followed closely the recommendations of the committee. In the Navy certain new rules were adopted in advance of the report of the committee, and under these rules a large proportion of men now invalided for pulmonary tuberculosis were allowed pensions under the attributable scale.

Cossham Hospital Inquiry.—On December 9th Mr. F. O. ROBERTS told Mr. Shillaker that he had received the report of the committee of inquiry into the Cossham Hospital and its administration. He had caused the report to be printed, and it would be available for members on December 10th.

Duties of the Board of Control regarding Pauper Mental Patients.—In a long statement to Major Glyn, on December 5th, regarding pauper lunatics Mr. GREENWOOD said that the powers and duties of the Board of Control in the case of mental patients on out-relief were limited to obtaining a return from the Poor Law authorities, and in the case of lunatics in Poor Law institutions to paying periodic visits. As regarded patients detained in county and borough mental hospitals the Board of Control examined the documents upon which these patients were received and detained and considered periodic medical reports. The Board also visited these institutions, and had general supervision over arrangements for care of the patients.

Detection of Gas in Mines.—Replying to Mr. Tom Williams, on December 4th, Mr. BEN TURNER said there had been eleven explosions in mines this year; in these twenty-eight persons lost their lives. So far as he was aware the only gas detector in use at the mines concerned was the *flame safety lamp. It* was unlikely that the use of a different gas detector would have prevented these explosions, six of which originated at open lights. Gas detectors other than flame safety lamps were in an early stage of development, and experience was not yet sufficient to judge their reliability and practical value as compared with the flame safety lamp.

District Medical Officers and the Local Government Act, 1929.—On December 5th Mr. DOUGLAS HACKING asked if Mr. Greenwood would take steps to prevent members of town councils who were also district medical officers under boards of guardians being included on Health Committees of boroughs for 1930, and whether such persons would be prevented from taking part in the setting up of Public Assistance Committees when they were actually paid servants of the Ministry of Health. Mr. GREENWOOD said that as the law stood district medical officers under the Poor Law who were transferred to county councils and county boroughs under the Local Government Act, 1929, would be automatically disqualified from membership of the council to which they were transferred.

Contagious Abortion in Cattle.—Dr. FREMANTLE addressed a question to Dr. Addison, on December 5th, concerning contagious abortion in cattle. Dr. ADDISON replied that in herds where the percentage of infection was not high the Ministry of Agriculture recommended that the disease should be controlled by hygienic methods and the agglutination test for the detection of infected animals. In herds where infection was heavy the Ministry advised the immunization of all non-pregnant animals with the live vaccine, which had been issued from the Ministry's laboratory since 1912, and was in demand. The disease did not lend itself to legislative control. Dr. FREMANTLE asked whether these methods had increased or reduced the incidence of the disease. Dr. ADDISON asked for further notice of this.

Notes in Brief.

Mr. Greenwood hopes the report of the Committee on Refuse Collection and Disposal will shortly be published.

The Minister of Transport has asked the London Traffic Advisory Committee to consider the advisability of making a regulation prohibiting the sounding of motor horns in residential areas of London between midnight and 5 a.m.

In 1926 the number of persons killed in Scotland by accidents caused by mechanically propelled vehicles other than tramcars and trackless trolley vehicles was 505; in 1927 it was 544; and in 1928, 576.

The Government proposes to introduce a bill amending the Children Act, 1908, and will bear in mind the proposal to extend the age of young offenders to 21.

Mr. Greenwood proposes to take no action concerning pharmacists in the Poor Law service in view of the changes which would take place when the Local Government Act, 1929, came into operation.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE George Herbert Hunt Travelling Scholarship is awarded without examination every second year to a graduate in medicine of the University (of either sex) who has not exceeded five years from the date of passing the final examination for the B.M. degree. The scholarship is of the value of £100, or such smaller sum as two years of the income of th[illegible] dates are required to submit with their [illegible] of their academic record, together with [illegible] (five copies) and an undertaking that, if elected, they will travel abroad for a period of not less than three months for the purpose of clinical study or research in medicine. In making the award a preference is given to such candidates as express the intention of engaging in the practice of their profession, either as surgeons or general practitioners. The scholar is required to complete his period of travel within twelve months from his election, and within a reasonable period thereafter to submit to the Dean of the School of Medicine a detailed report of his tenure of the scholarship. The next election will be made in April, 1930. Candidates must send their applications to the Dean of the School of Medicine, University Museum, Oxford, on or before February 11th, 1930.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on December 6th the following medical degrees were conferred:

M.D.—*W. L. Harnett, K. E. Harris, J. D. M. Stewart, R. A. Hickling.
B.Chir.—W. E. Mashiter, C. G. Townsend.

* Admitted by proxy.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examinations indicated:

M.D.—W. A. Gornall.
FINAL M.B., CH.B. (*Part I, including Forensic Medicine and Toxicol[illegible]*): A. Barnabas, J. E. Brown, H. L. Cleave (o[illegible]sic Medicine and Toxicology), J. L. S. C[illegible] Materia Medica, Pharmacy, Pharmacology, and Therapeutics), C. J. N. Davis, F. W. A. Foxbery, L. R. Jordon (with distinction in Pathology), J. A. Kersley, R. H. Moore, Elizabeth S. G. Owen, C. N. Royal, W. A. F. Taylor; (*in Part I only*) L. P. Ashton. (*Part II*): J. J. J. Giraldi (with second-class honours), J. E. Newton, N. C. Tanner. (*In Group I, completing examination*): N. L. Price. (*In Group II, completing examination*): N. D. Gerrish, Mabel F. Potter. (*In Group II only*): R. M. Norman.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE annual meeting of the Royal College of Physicians was held on December 5th. Sir Norman Walker was elected President, Dr. Robert A. Fleming was nominated Vice-President, and the following were elected members of Council for the ensuing year: Dr. G. Lovell Gulland, C[illegible] Dr. John Orr, Dr. William Fordyce, Dr. Edwin Bramwell, a[illegible]

At the extraordinary [illegible] Dr. John Orr and Dr. W. Fordyce were elected representatives of the College on the Board of Management of the Royal Infirmary of Edinburgh.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following have been admitted Fellows of Faculty: A. M. Clark, *M.C.*, J. Ferguson, W. D. H. Stevenson, Rosie Swamikan.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

THE following have been admitted Licentiates in Medicine and Midwifery: M. J. Duffy, A. E. Flannery, T. J. Harkin, G. J. Harrison, J. Lennon, P. B. M'Carthy, T. M'Carthy, T. J. A. M'Hugh, P. M'Inerney, W. H. Peirce, F. O'C. Walsh, J. R. H. Weir.

The President (Dr. W. A. Winter) has been unanimously nominated to represent the College as a member of the executive council of the Queen's Institute of District Nursing in Ireland for a period of three years.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved at the examination indicated:

MASTER OF MIDWIFERY.—Lilly A. Baker, N. R. Macadam, W. G. Richards, G. C. Soutter.

The Services.

No. 14 STATIONARY HOSPITAL.

THE tenth annual dinner of the No. 14 Stationary Hospital was held at the Trocadero Restaurant, London, on December 6th. In the absence of Colonel C. R. Evans, D.S.O., the chair was taken by Lieut.-Colonel J. R. Harper, C.B.E., who proposed the toast of "The Hospital," and commented on the pleasure caused by these annual reunions. Colonel J. S. Warrack replied. Dr. H. L. Tidy, the organizer of the dinner, contributed information about members of the hospital staff who had been prevented from being present, and thus started the usual flow of reminiscences which Colonel Michael Foster, O.B.E., and others continued. In view of the high percentage of the surviving members of the staff who had attended the dinner during the last ten years, it was agreed that the future prospects of these reunions were bright.

Medical News.

SIR E. FARQUHAR BUZZARD will deliver the Purvis Oration before the West Kent Medico-Chirurgical Society in the Nurses' Lecture Room, Miller General Hospital, Greenwich, to-day (Friday), at 8.45 p.m.; the subject is "The dumping-ground of neurasthenia."

THE seventh and last lecture of the People's League of Health new series on racial and individual welfare will be delivered to-day (Friday, December 13th) at the House of the Medical Society of London, Chandos Street, W., at 6 p.m., by Dr. R. O. Moon; his subject is "The British contribution to medicine."

A MEETING of the Royal Microscopical Society will be held at 20, Hanover Square, W.1, on Wednesday, December 18th, when Mr. F. V. Welch, F.R.M.S., will read a paper on a microscope lamp, and the president, Mr. J. E. Barnard, F.R.S., will contribute a note on dark-ground illumination.

A THREE months' course of lectures and demonstrations on clinical practice and in hospital administration will be given at the North-Eastern Hospital of the Metropolitan Asylums Board, St. Ann's Road, Tottenham, N.15, by the medical superintendent, Dr. F. H. Thomson, on Mondays and Wednesdays at 4.45 p.m., and alternative Saturdays at 11 a.m., beginning on Monday, January 6th, 1930. The fee for the course, which complies with the requirements of the revised regulations, is £3 4s. A course under the old regulations may be taken for £3 3s. Applications, enclosing cheques made payable to the Metropolitan Asylums Board, should be addressed to the Clerk of the Board, Victoria Embankment, E.C.4.

IN connexion with the Yorkshire Council of the British Empire Cancer Campaign and the Clinical Medical Studies Committee of the Faculty of Medicine, a lecture on intra-thoracic and pulmonary new growths was given on December 3rd at the University of Sheffield by Dr. Maurice Davidson, physician and dean of the Medical School, Brompton Hospital, London. The lecturer referred to the undoubted increase of malignant disease affecting this region during recent years. He quoted statistics showing that such increase had been observed in various parts of Europe with surprising uniformity. The lecture dealt primarily with the clinical aspects of the subject, and was illustrated by a large number of specimens and radiograms. There was a large attendance of practitioners, and the lecture was greatly appreciated.

AT the eighth annual meeting of the Scottish Women's Hospital Association, held at the Royal Free Hospital on December 3rd, H.R.H. the Duchess of York as president received purses amounting to £5,285 for a scheme to commemorate heroic Scotswomen. The association, which worked in most of the fields of operation during the war, has raised the money to build and equip a new ward in the maternity wing of the Royal Free Hospital and a maternity centre at Islington named after the Duchess of York. Each bed will be named after a unit or after a member who gave her life in service; one will bear the inscription "In proud memory of Dr. Elsie Maud Inglis, founder of the Scottish Women's Hospitals in the Great War, who gave her life in devoted service in Serbia in 1917." The Duchess of York presented to Lord Riddell, president of the hospital, three name plates, one each for the Edith Palliser bed and the Serbian Units bed respectively, and the third to be affixed to an operating table given by the Royaumont Association, which was the first of these hospital units to take the field. On the motion of Lady Barrett, seconded by Miss Frances Ivens, it was agreed that, having completed the memorial, the association should in future be known as the Royal Free Hospital Scottish Women's Hospitals Memorial Association, and should endeavour to provide annual maintenance for the eight memorial beds.

AT a meeting of the president and trustees of the North Staffordshire Royal Infirmary, on December 3rd, it was announced that the late Miss Dora Twyford, of Whitmore Hall, near Newcastle, Staffs, had left £50,000 from her residuary estate to the infirmary. When Miss Twyford died, some five years ago, she bequeathed £12,000 to the infirmary for a new wing in memory of her father and mother.

THE report presented to the annual meeting of the Royal Surgical Aid Society, held at the Mansion House on December 3rd, showed that the total income had been £56,679. The expenditure amounted to £55,678, of which £46,917 had been spent on surgical appliances. During the year assistance had been given to 29,262 cases and 40,254 surgical appliances supplied, making the grand total since the formation of the society in 1862 of 903,431 and 1,353,831 respectively. Special grants had been made in cases where patients were unable to procure the requisite number of letters; in that way 7,644 letters had been bestowed during the year. The report referred to the very serious loss the society had sustained by the recent death of Mr. T. H. Openshaw, who had been associated with it for thirty years.

THE annual report of Livingstone College for the year 1928-29 contains an account of the annual meeting in June, to which reference was made in our columns on June 29th (p. 1183). Emphasis is laid on the value to missionary societies of the useful training in health preservation and the treatment of minor disorders which is provided for those proceeding overseas to take up missionary work in remote districts; letters from China, India, and Africa are reproduced, illustrating how this instruction has proved beneficial in emergencies. During the year under review twenty-three missionary organizations and seven nationalities were represented by fifty-nine students, who took either the full or shorter courses. Receipts exceeded expenditure during the year, and the deficit was reduced by £117. It was, however, necessary to postpone certain needed repairs and improvements, and more liberal subscriptions and donations are urgently desired.

BY issuing *Clean Air*, a new quarterly journal, the National Smoke Abatement Society adds "still one more magazine to the thousands which are poured out from the presses every day, week, month, or quarter," but the first devoted to the cause for which the society exists. In the opening number are printed messages of congratulation from persons eminent in politics and science, and articles on domestic heating and the use and development of gas and electricity in industry. The annual subscription, payable to the Editor, *Clean Air*, 23, King Street, Manchester, is 2s. 6d.; single copies may be obtained at the price of 1s.

A SOCIETY of parasitology has been founded at Leningrad, under the presidency of Professor E. N. Pavlovsky of the Military Academy of Medicine.

A PARACELSUS SOCIETY has recently been founded at Munich, with Professor Karl Sudhoff as president of honour.

PROFESSOR OTTO GANS of Heidelberg has been made a corresponding member of the Società Italiana di Dermatologia e Sifilografia; Dr. August Siegrist, professor of ophthalmology at Berlin, an honorary member of the Société Française d'Ophtalmologie; Professor Weygandt of Hamburg, an honorary member of the Section of Psychiatry of the Royal Society of Medicine; and Dr. Memmesheimer, director of the university skin clinic at Tübingen, an honorary member of the London Dermatological Society.

Letters, Notes, and Answers.

All communications *in regard to editorial business should* be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

THE PLOMBIÈRES DOUCHE IN CHRONIC CONSTIPATION.

"J. D." asks: Would any of your readers be kind enough to let me know his experience in the use of the Plombières douche for chronic constipation? Is it injurious? Is it efficient in re-educating the intestine and developing the daily rhythmic peristaltic movement of the intestine?

TREATMENT OF CHRONIC PRURITUS ANI.

"H. F." asks for advice in treating a case of chronic pruritus ani. The patient has an area of skin, about 1 in. around the anus, which is slightly oedematous and has many small cracks in it. These cracks have been touched with silver nitrate with no satisfactory results. The patient is very depressed and almost melancholic. A proctoscopic examination has established the absence of piles.

TRANSIENT ATTACKS OF OEDEMA.

DR. E. MURPHY (Cork) writes: In reference to Dr. Lowman's inquiry in the *Journal* of November 23rd (p. 991), I remember a case of a girl, aged 7 years, who suffered from general oedema, with no symptoms of heart or renal trouble. I was informed that she had an inordinate love for salt, taking it from the salt cellar as though it was sugar. On preventing the child from obtaining salt, she rapidly recovered, and was able to leave her bed. I would advise Dr. Lowman to inquire as to his patient's food.

DENTAL ANAESTHESIA FOR CHILDREN.

MR. A. J. MAURICE, L.D.S. (London, W.), writes: In answer to "W. D." (November 30th, p. 1019), if your correspondent would adhere to ethyl chloride throughout, without changing to ether, I think he would get a better result. In my practice, the hospital portion of which, unfortunately, includes a large number of extractions for children, I always operate on patients up to 12 years of age under ethyl chloride given by the closed method. In children over 12 years of age I find that nitrous oxide is the most satisfactory anaesthetic. If it is desired to get a longer anaesthesia than nitrous oxide alone offers, one can have recourse to nitrous oxide followed by ethyl chloride.

DR. W. C. SHARP (Holytown) writes: In reply to the inquiry by "W. D." as to the best anaesthetic for dental work in the case of children and young persons, may I suggest that nitrous oxide-oxygen, either with or without ethyl chloride, is the anaesthetic of choice. It is safe, efficient, and expeditious, and being rapidly eliminated, there are practically no after-effects. The vapour is not unpleasant, and I have not found any undue fear of the face-piece, even with young children. The Guy-Ross method of administration is most suitable, although I prefer a slightly modified apparatus. It is best to add several pumpfuls of oxygen to the nitrous oxide before applying the face-piece; during induction keep up the oxygen content of the bag, using the patient's colour as a guide. The younger the patient the greater is the volume of oxygen required. Very young children will hardly need ethyl chloride at all. I have always found a maximum of 1 c.cm. sufficient for any child.

DR. CUDRIC COXON (Dersingham, Norfolk) writes: From a dentist's point of view "open ether" is the anaesthetic that answers all purposes, and I suggest that "W. D." should employ the "safety first" anaesthetic, in spite of the opinion of one or two restive dentists. I have had considerable experience of general anaesthesia, both in private and in hospital practice; where I can use it I prefer ether, continuing it as nasal combined with oxygen or nitrous oxide and oxygen, from a Boyle's apparatus, if necessary. For young people who require only a few extractions, and there is a choice of anaesthesia, always use open ether; it is nearly always possible to finish operating without having to re-induce.

INCOME TAX.

Cash Basis: Death of Partner.

"S. H. B." was in practice as a partner until his death on March 30th, 1929. The partnership accounts have been made up to December 31st annually, and the liability of the firm for the year to April 5th, 1929, was assessed on the basis of the account for the year to December 31st, 1927, the receipts being shown at the gross amount of cash received in that year. What is the position of the executors and of the surviving partner?

*** The general question of the cash basis was discussed with an official representative of the Inland Revenue Department some years ago, and, so far as our knowledge goes, is still regarded by the authorities in the same way, notwithstanding the changes effected in the law by the Finance Act of 1926. In its view—and we are unable to controvert it—the legally correct method of preparing a practitioner's account is to compute the receipts at the amount of the year's *bookings*, less an allowance for irrecoverable amounts arrived at after a detailed examination of the ledger. It was, however, agreed that this involves a troublesome process, and, further, that where the practice has reached normality, so that the receipts year by year are reasonably steady, then, in the long run, the same result is reached, whether the receipts are calculated on the "cost" or the "bookings" basis. Consequently, while it was made clear that the department does not admit any legal right to the cash basis, and is not prepared to enter into any arrangement to apply it, nevertheless it is prepared to acquiesce in that basis in suitable cases. Applying that line of reasoning to the present case, it would seem to follow (1) that there is no liability on the executors to account for tax on the debts collected after December 31st, 1927—the income has been adequately assessed for the period to April 5th, 1929; (2) that the surviving partner will be liable to account for tax on the whole of the profits of the practice as from the latter date; and (3) that in assessing that income for the year to April 5th, 1930 (no notice to break the previous year's method of assessment having been given under Section 32 (1), Rule 11 (1) of the Finance Act, 1926), the profits will have to be taken at the amount of the income of the practice for the year to December 31st, 1928; if that was a normal year it can, no doubt, be calculated on the basis of the cash receipts of the practice for that year, otherwise the "bookings" basis will have to be applied. The same result is reached for 1930-31, it being remembered that if the cash basis is applied, then *all* such receipts, whether taken by the executors or the surviving partner, must be brought into the computation.

LETTERS, NOTES, ETC.

TREATMENT OF THE ORDINARY COLD.

DR. STANLEY E. DENYER, C.M.G. (Hull, writes: During the last two or three winters I have been using for the ordinary cold a simple treatment, which consists of a small quantity of quinine sulphate, about as much as one would put on a threepenny bit, dissolved in about a quarter of a sherry glass of cooking sherry. This can be taken two or three times a day. If a dose is taken at the beginning of a cold, in many cases it will prevent its development. A patient whom I have been treating for tuberculous disease of the lung—dullness, loss of tactile vocal fremitus, marked shadow to *x* ray in the same area, weakness, and slightly raised temperature—frequently and easily caught cold; when he did, he always had pain in the upper part of the left chest, the seat of the trouble. He was directed to take quinine as described above, and has informed me that it always cut short the colds; in addition, it always relieved the pain in his chest, which in every case previously had been moderately severe, whenever he started a cold. He volunteered this information without any question on my part. Many have told me that the quinine and sherry have certainly stopped a cold in its beginning. It is necessary to use cooking sherry. On the one or two occasions that a good sherry has been used I have not found it nearly so effectual; it is a pity to spoil a good sherry with quinine. Cooking sherry contains more acid than the better varieties of sherry, as will be easily shown by the much more rapid way in which quinine dissolves. It also seems to act better, probably because, being better dissolved, it is more readily absorbed.

RACIAL INCIDENCE IN DISEASE.

DR. J. STEWART MACKINTOSH, in the course of a letter winding up this discussion, writes: Once more I must beg Dr. Sourasky to read my letters with closer attention. All I did was to propound a theory which seemed to accord with biological law and adduce prima facie evidence in support of it, asking at the same time for independent investigation. The principle concerned is that a race evolved in one environment will, on migration to another, experience stress whenever and wherever the new differs from the old; and that physical and mental traits which have a survival value in one environment may be a handicap in another. Dr. Sourasky seems to be unaware that the racial origins of the British people have been explored in the most thorough-going way. I have some acquaintance with current views as to the ethnology of the modern Jew, and find nothing to rebut my suggestion that he, like certain other types in this country, is warmed and cooled by the same summer and winter—not quite as the rest of us. I gave reasons in my first letter (October 5th, p. 647) for believing that this also applies to other intrusive elements (as distinct from the Neolithic substratum) in the composition of the British people. Do not, for instance, our upper classes, predominantly Nordic, find exhilaration in the dry and sunny Alpine winter, in part at least, because they are regaining climatic conditions lost to them by the migration of their ancestors? For this type also seems prone to catarrh and its sequelae when exposed to damp and cold—particularly as regards soil—and statistics have conclusively proved its inadaptability to urban life, a fact to be explained by its racial inexperience thereof.

MOTORIST'S KNEE.

"R. V. S." writes: It seems there are numerous disabilities caused by motor driving. From personal experience I can say there is a form of motorist's knee. Two years ago I bought an American type of car in which the control pedals are stiff and placed high off the floor boards, so that one cannot rest the heel on the floor boards when pushing out the clutch or adjusting the foot brake pressure. I developed severe pain and stiffness in both knees, more particularly in the inner sides over the internal lateral ligaments. This must have set up a form of fibrositis, as it is still troublesome. I am sure the position of the foot controls is wrong.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 264.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

523. Essential Hypertension.

A. S. GRANGER (*Journ. Amer. Med. Assoc.*, September 14th, 1929, p. 819) defines primary or essential hypertension as that unaccompanied by nephritis, hyperthyroidism, aortic insufficiency, or any other condition usually associated with a rise in blood pressure. Essential hypertension is characterized by a persistent systolic pressure of 145 mm. of mercury or over, and a left ventricular cardiac hypertrophy, without demonstrable cause, though the hypertension may exist in the early stages without the cardiac enlargement. It is a progressive disease, probably beginning in the second and third decades of life and ending usually from the third decade on, by heart failure, cerebral accidents, or renal insufficiency. There is no known definite cause for this type of hypertension, but the factors most concerned are heredity and vasomotor hyper-irritability. Vascular lesions of the medulla, affecting the vasomotor centre, may produce a rise in the systemic pressure, but the hypertension may precede such lesions. Other factors are sclerosis of the arterioles of the medulla, endocrine disturbances, renal vascular alterations, obesity, and infection. Sclerotic changes in the renal arteries and their branches, especially in the afferent arterioles of the glomeruli, are almost pathognomonic, and are the most common pathological finding. The next most frequent is hypertrophy of the heart, particularly of the left ventricle. The degree of the diastolic pressure is probably of greatest moment in determining the prognosis, a high figure being of serious import. Treatment should be directed mainly to regulating the life and habits of the patient, so as to promote rest, freedom from worry and aggravation, and moderate pleasurable exercise. Dietary restrictions are of use only in the obese, or when cardiac or renal incompetence occurs. Drugs have a very limited applicability in this condition. A frank discussion of the ailment by the physician and the patient is advisable in most cases.

524. Symptoms and Treatment of Coronary Thrombosis.

R. SINGER (*Wien. Arch. f. innere Med.*, October 10th, 1929, p. 421), who has seen 20 cases in the course of the last three years, states that acute coronary thrombosis is characterized by anginal pains lasting for hours; they are not affected by nitroglycerin, and are followed by hyperaesthesia. In cases of involvement of the left ventricle Cheyne-Stokes breathing is present, though it may not be pronounced. The following symptoms, though frequent, are not constant: changes in cardiac rhythm, such as tachycardia, bradycardia, and extrasystoles, signs of failing compensation, and digestive disturbances, including meteorism, anorexia, and vomiting. The prognosis depends on the extent of the myocardium involved. Of the 20 cases studied 7 patients died—a mortality of 35 per cent.; five in the first attack, and two in the next eight weeks owing to recurrences. The other patients, in some of whom the condition has lasted for over three years, are in fairly good health in spite of having plenty of work to do. Treatment consists principally in absolute rest in bed for at least ten to fourteen days after complete cessation of all symptoms. Each patient should be given morphine and quinidine at once. About a fortnight after the attack a course of intravenous euphyllin should be started. Digitalis should be exhibited only in small doses when signs of failing compensation occur. Symptoms of angina or hyperaesthesia which persist are frequently benefited by Zulzer's cardiac hormone and *x*-ray treatment.

525. The Blood Pressure in Scarlet Fever.

J. A. EDELMANN (*Jahrb. f. Kinderheilk.*, October, 1929, p. 167) examined the blood pressure in 410 cases of scarlet fever in the children's department of the Workmen's Hospital at Kiev, and came to the following conclusions. In the first week of the disease the number of patients with a raised blood pressure exceeds those without any rise and amounts to 65-70 per cent. In the second and third weeks the number of cases with a rise of blood pressure begins to fall rapidly and is almost the same as those without any rise of blood pressure, especially if mild uncomplicated cases are included. In cases complicated by nephritis from the first or at a later stage this fall is not observed. From the beginning to the end of the third week the number of cases with increased blood pressure begins to rise again, amounting to 70 per cent., and even 80 to 90 per cent. when the cases complicated by nephritis are included. The increase of blood pressure in nephritis is shown by a sharp rise of 20–30 mm. Hg and more. As the blood pressure appears to be raised in cases complicated by nephritis from the first before the appearance of this complication, these cases may be regarded as possessing a certain renal insufficiency, which is the predisposing cause of the nephritis. The present series confirms numerous observations as to familial predisposition to scarlatinal nephritis. Severe attacks of scarlet fever have the same hypertensive effect as scarlet fever generally. In the majority of cases (76 per cent.) the rise and fall of the minimum pressure corresponds with that of the maximum pressure. The usual method of determining the diastolic pressure as introduced by Korotkow cannot be regarded as reliable, so that there should be considerable caution in accepting estimates of the diastolic pressure.

526. Weil's Disease without Jaundice.

G. C. VAN DEN HEUVEL (*Nederl. Tijdschr. v. Geneesk.*, October 12th, 1929, p. 4791) records the case of a boy, aged 11, who after swimming in a bath, the water of which was in communication with that from a slaughterhouse, was seized with vomiting, fever, severe headache, and general malaise. Apart from slight abdominal tenderness, there were no physical signs. A diagnosis was made of acute gastro-enteritis owing to its prevalence at the time (July). In spite of a purgative the fever remained high and the patient had attacks of epistaxis; herpes labialis developed, the liver and spleen became palpable, and there was considerable conjunctival injection, but jaundice was absent, and the urine remained normal. The possibility of Weil's disease was then considered, and examination of the blood showed an agglutination to *Leptospira icterohaemorrhagiae* in 1 in 25,000; leptospirae were also found in the urine of experimental animals. Apart from the abdominal pain, there was no pain in the muscles, and there was no eruption. Recovery was uneventful, the temperature becoming normal on the eleventh day.

527. Primary Diphtheria of the Lingual Tonsil.

L. NICOLAI (*l'Ospedale Maggiore*, September 30th, 1929, p. 298) records a case of primary diphtheria of the lingual tonsil in a woman, aged 62, who while convalescing from influenza complained of headache and difficulty in moving the tongue and swallowing. On examination the central part of the descending surface of the tongue showed a thick adherent exudate which bled on being detached. Nothing abnormal was seen in the fauces and tonsils, but there was moderate enlargement of the submaxillary glands, especially on the right side. There was fairly profuse sialorrhoea, the breath was fetid, and there was a trace of albumin in the urine. Bacteriological examination showed the presence of diphtheria bacilli. Three injections of antitoxin were given, and the condition gradually cleared up without being followed by any complications.

Surgery.

528. Electrocautery in Prostatic Obstruction.

C. P. MATHÉ (*Urol. and Cut. Rev.*, October, 1929, p. 652), who records three illustrative cases, states that dividing or tunnelling the prostatic bar by the use of the high-frequency current through the cystoscope is a useful procedure, and can always be employed in relieving obstructions due to median lobar hypertrophy, to hypertrophy of the collar type, and to atrophy caused by sclerosis. This method is also applicable to cases presenting the early stages of hypertrophy of the median and lateral lobes, and to cases with bad surgical risks, as well as in a large number of so-called borderline cases usually treated by prostatectomy. In many of these the retention is due to inflammatory enlargement with spasticity of the sphincter and not to hypertrophy of the gland. The method does not supplant prostatectomy, which should be reserved for cases in which the gland has reached a considerable size. It is a simple procedure which can be performed under local anaesthesia, is followed by little general reaction, involves no risk of death, and is less likely to be accompanied by complications such as epididymitis, embolism, seminal vesiculitis, and incontinence. Moreover, the sexual power is less likely to be weakened and reproductive power is preserved. In 51 cases under the author's care the immediate and ultimate results were excellent in the median lobe hypertrophy, sclerotic atrophy, and collar type hypertrophy.

529. Idiopathic Peritonitis in Children.

W. OBADALEK (*Deut. Zeit. f. Chir.*, Heft 3-6, Bd. 220, November, 1929, p. 307), whose paper is based on 50 cases treated in the Children's Hospital at Brünn since 1920, states that idiopathic peritonitis in children is not a rare event. It is most frequent in girls, only 9 of the series being boys. The cause for this is not a genital infection, but the different relations of the peritonitis in the two sexes. In only 3 of the 50 cases could an ascending genital infection be proved, due in one case to the streptococcus and in two to the gonococcus. In all the rest an enterogenous origin appeared to be the most probable, the causal organisms being pneumococci, streptococci, staphylococci, or *B. coli*. The most frequent starting point of the peritonitis was found to be the lower end of the small intestine, the peritoneal covering of which appeared to be more severely affected than the other segments of the intestine, while the appendix was the next most frequent originating site. In the absence of other complications the long duration of the fever was caused by infection of the mesenteric glands, but if this did not occur the fever soon came to an end by rapid lysis. Owing to the danger of metastasis, early operation is less dangerous than expectant treatment even in pneumococcal peritonitis. The gravity of the prognosis in idiopathic peritonitis is shown by the fact that of 47 patients on whom an operation was performed 16 died—a mortality of about 34 per cent.

530. Fracture of the Acetabulum.

F. G. DIAZ (*Bull. et Mem. Soc. Nat. de Chir.*, November 2nd, 1929, p. 1135) reports the case of a man, aged 28, who was admitted to hospital with the diagnosis of recurrent dislocation of the left hip-joint. A preliminary examination gave the impression that the dislocation had been completely reduced as the leg was in a correct position, could be fully extended, and movement was possible although painful. Under a light anæsthetic a loose body was discovered in the joint which made complete flexion of the leg impossible without great effort; at the moment of this flexion the head of the femur came out of the acetabular cavity, but could be put back again easily. The patient gave a history of an accident when he was felling trees, after which his leg appeared to be fixed in an extended position with internal rotation. By means of *x* rays it was seen that the reduction was not perfect and that a fragment prevented the reduction of the head of the femur in the joint. Surgical intervention consisted in fixing the fragment by suturing its free edge to the adjoining tissues in the hope of obtaining satisfactory union. Subsequent *x*-ray examinations showed that this had not taken place. At the end of two months the patient could walk with the help of two sticks, but complained of pain and weakness in the injured limb. Mobilization in flexion was possible to 90 degrees, in abduction to less than 45 degrees, while rotation was limited; the results were therefore only partially satisfactory. The small size of the particle made fixation by means of a metal plate impracticable. It is pointed out that a more satisfactory result might have been obtained if an attempt had been made to form a buttress of bone by using the fragment as a bone graft.

531. Surgery of Pylorospasm.

J. B. DEAVER and V. G. BURDEN (*Annals of Surgery*, October, 1929, p. 530) record the results in 31 cases treated by them in which an operation which they call pylorohemisphinctercetomy was employed in the treatment of duodenal, gastric, and gastro-jejunal ulcer and pyloroplasm, associated with hyperacidity, or with disease of the gall-bladder and appendix. The theory of the operation is based upon the correction of malfunction of the pyloric sphincter. The upper part of the [illegible] rectus is incised and the exposed gastro-duodenal area is effected [illegible] held under tension by drawing the stomach out and to the left [illegible] correct anatomical relations. An elliptical area including the anterior half of the pyloric sphincter is formed by two curved transverse incisions, carried down to the submucosa of the stomach and duodenum on either side of the sphincter. The lower end of this area, with the sphincter, is cut across, peeled off [illegible] mucosa, and cut again across the [illegible] gastric and duodenal serous edges are [illegible] sutured, and the operation leaves no [illegible] pyloric outlet. Wide extension [illegible] and the presence of scar tissue due to a nearby ulcer, are contraindications to the operation. In most cases the ulcer is not disturbed, but sometimes it is excised, and the anterior half of the sphincter is removed. In three cases of acute perforation of a duodenal ulcer the perforation was closed and the sphincter resected. In the 31 cases under review, duodenal ulcer was found in 23, of which three were acute perforations; there were three cases of gastric ulcer, nine of cholecystitis, of which seven had an associated duodenal ulcer, and two pyloro-spasm. There were four cases of pylorospasm and one of gastro-jejunal ulcer. The anterior half of the pyloric sphincter was excised in all cases, and additional operative procedures included excision of a duodenal ulcer in four cases, gastro-jejunostomy in one case, cholecystectomy in nine cases, and sleeve resection of the stomach in two cases. Only 18 patients reported subsequently, and of these 15 were completely relieved of symptoms, two were greatly improved, and one had gained only moderate benefit. In 12 cases *x*-ray examination after operation showed no gastric retention, no hyperperistalsis, and only slight deformity of the pyloric canal.

Therapeutics.

532. Malaria Therapy in Diseases of the Nervous System.

D. PAULIAN (*Presse Méd.*, October 23rd, 1929, p. 1375) summarizes several hundreds of cases treated by malaria therapy and by other (non-malarial) pyreto-therapeutic methods. Malarial inoculations produced the following results: in general paralysis 30.4 per cent. remissions, and 34.1 per cent. improvements; in meningo-encephalitic syphilis the respective figures were 44.6 per cent. and 32.3 per cent.; in tabo-paralysis 33.3 per cent. and 30.3 per cent.; in tabes *nil and 65.7 per cent. In syphilitic optic atrophy there was* practically no result. All the patients were also treated with arsenic, bismuth, and mercury. Malaria therapy was also used *in certain non-specific nervous affections*: post-encephalitic Parkinsonism (12 cases), epilepsy (8), disseminated sclerosis (3), spasmodic paraplegia of medullary origin (4), and dementia præcox (5), but the results were almost negligible, though *in manic-depressive psychosis the phase of excitement* is reported to be often shortened. Among non-malarial methods of pyreto-therapy were tried: recurrent fever; tuberculin and antityphoid vaccine; neuro-yatren; and milk, sodium nucleinate, and phlogetan. The results of undulant fever infection were very poor, while tuberculin was found to be useless and dangerous. Antityphoid vaccine administration improved some cases of general paralysis, meningeal syphilis, and tabo-paralysis, but the results were poor compared with those of malaria therapy. In non-specific nervous diseases, however, it is claimed that there was total remission in six cases of mental confusion, and marked improvement in 23 cases of post-encephalitic Parkinsonism; in these cases vaccine therapy was associated with the exhibition of calcium chloride and sodium cacodylate. The vaccine "neurin" (a mixture of staphylococci and *B. prodigiosus*) is said to have improved six cases of disseminated sclerosis. Neuro-yatren (a complex suspension of bacteria) was of considerable benefit in four cases of post-encephalitic Parkinsonism, in six cases of disseminated sclerosis, in four cases of adhesive meningitis, and, above all, in thirty cases of infantile paralysis. The results of milk injection were not encouraging. The conclusion is reached that malaria therapy constitutes the treatment of choice of general paralysis, of meningo-encephalitic syphilis, and of tabo-paralysis. Non-malarial pyreto-therapy is a useful adjuvant, and should be employed in all cases where the patient is too debilitated, where there is no reliable source of malaria, or where too high a temperature would aggravate the existing illness. Among the advantages of this latter treatment should be noted the ability to control the raised temperature in each case, and the possibility of reinforcement by different adjuvant or specific therapeutic agents.

533. Idiosyncrasy for Potassium Sulphocyanate.

C. R. WEIS and R. RUEDEMANN (*Journ. Amer. Med. Assoc.*, September 28th, 1929, p. 988) report a case of exfoliative dermatitis caused by potassium sulphocyanate therapy; they believe that this is a hitherto unrecorded complication of the treatment for essential hypertension. A man, aged 37, complained of dyspnœa and cough; he suffered from hyperthyroidism and essential hypertension. The blood pressure was 240/140, and he had cardiac hypertrophy and dilatation. After a course of digitalis and iodine treatment thyroidectomy was successfully performed, and, since the blood pressure remained unchanged, he was given 1½ grains of potassium sulphocyanate three times daily for the first week and twice daily for the second week. On the tenth day an acute diffuse erythematous dermatitis appeared, involving the face, neck, hands, forearms, and ankles; it was preceded and accompanied by burning and itching, and reached its maximum intensity after four days. The dermatitis cleared up rapidly upon withdrawal of the drug, alkalization of the patient, dieting, and giving colloid starch-soda baths. Six weeks after the condition had completely disappeared potassium sulphocyanate treatment in much smaller doses

was again commenced, but three days later an acute inflammatory erythematous dermatitis reappeared, though in a less severe form. This second attack was thought to be sufficient proof that the potassium sulphocyanate was responsible for the condition, and the authors regard the incident as another example of an unfavourable result from its use, in addition to those already recorded by Palmer and Sprague.

534. Liver Diet in Pernicious Anaemia.

V. SCHILLING (*Dent. med. Woch.*, October 11th, 1929, p. 1701) has analysed 80 cases of pernicious anaemia treated with liver diet since February, 1928; in 14 of these relapse had followed the discontinuance of liver treatment, but resumption of the treatment resulted in benefit. Six patients died, but two of these had only been under treatment for a few days; in the remainder death followed such complications as hydronephrosis and tabo-paralysis, and no post-mortem evidence was obtained of severe anaemia. In a number of cases which did not respond to liver treatment promptly, adjustment of the dose and the substitution of whole liver extracts (on which Schilling lays great stress) usually brought rapid improvement. Only one patient in whom the anaemia was complicated by menorrhagia became worse in spite of the treatment, though some senile patients were slow to respond. In two with degeneration of the spinal cord this condition was apparently checked, and the symptoms improved. Schilling concludes that liver diet has proved successful, practically without exception, in this large series of cases, provided that the dose was adapted to the individual, the apparent failures being all due to severe complications.

535. R. SEYDERHELM (*Ibid.*, p. 1704) reports three cases of pernicious anaemia in which severe symptoms of intoxication of the nervous system followed the administration of liver; these included hallucinations, disturbances of speech, and coma, while the blood remained normal. The author states that before the introduction of liver diet such symptoms were never observed, those cerebral symptoms which did occur in the later stages of the disease being directly attributable to the anaemia. He also mentions that the onset of an intercurrent infection such as cystitis or pyelitis (which is particularly liable to occur in cases with degeneration of the spinal cord) was frequently followed by a reduction in haemoglobin and erythrocytes; this persisted until the quantity of liver which had previously sufficed was augmented. Seyderhelm concludes that though liver diet may replace a hormone normally produced in the liver, and thus relieve the actual anaemia, it must be considered rather as a palliative of one group of symptoms than as a cure for the disease, since the achlorhydria persists and degeneration of the cord tends to progress. The syndrome of pernicious anaemia, when the anaemia is relieved by liver diet, is being in fact replaced by a pernicious myelo-encephalo-toxicosis, due to a toxic factor which remains unidentified.

536. Subcutaneous Injections of Oxygen.

V. MIKULOWSKI (*Wien. klin. Woch.*, August 8th, 1929, p. 1018) discusses the administration of oxygen in the children's clinic at Warsaw, with special reference to its subcutaneous injection into infants suffering from croup. He gives daily injections of about 100 c.cm. for a week or so in cases of emergency, particularly when croup is associated with pneumonia and intense cyanosis. He comments favourably on the results so obtained, but emphasizes the need of associating this procedure with the usual methods of treatment, such as intubation, tracheotomy, and the administration of serum. He agrees with other investigators that in older patients far larger volumes of oxygen can be injected into the body with benefit, particularly in cases of haemorrhage and certain infections, such as typhoid fever.

Laryngology and Otology.

537. Treatment of Nasal Suppurations.

GRAIN (*Rev. de Méd.*, 1929, No. 7, p. 763) thinks that nasal suppurations, which frequently lead to serious sequels, do not receive the attention they merit. The nasal fossae are not inert organs, and their degree of health governs in a very large degree the vitality of the entire organism. Nasal suppuration may be acute or chronic. At the onset the infection is limited to the mucosa, both of the nasal fossae and of its prolongation into the aural annexa. The glandular system is rapidly invaded, and the infection soon spreads to the periglandular cellular tissue in the submucosa. The condition then becomes chronic, leading to hypertrophy of the mucosa and conditions of the turbinates which often necessitate long and complicated surgical intervention. Treatment mainly consists of two methods- the antiseptic and the vaccinal. No variety of the former—aqueous or oily solutions, ointments, or powders—is advised owing to its non-specificity, non-diffusibility, and coagulating action on the tissue albumins. Grain advocates strongly vaccine therapy, both general and local, and reports six cases in support of this view. Local treatment consists in placing sterile cotton pledgets, soaked with a polyvalent auto-antivirus, in contact with the middle and, if possible, with the inferior turbinate; the nasal fossae should also be freely swabbed with the antivirus. The patient must avoid blowing his nose, unless necessary, for the succeeding two hours. This treatment should be applied daily, and even twice a day in very acute cases. The applications should be bilateral, the rhino-pharynx be immunized, and treatment continued till all traces of suppuration have disappeared. As general treatment, injections of a polyvalent autogenous vaccine are given every two days in doses of 0.5 c.cm., which are gradually increased to 2 c.cm. The local application is the essential treatment, the general being only an adjuvant, though a necessary one. In long-standing cases in which the bone has become affected, and in those presenting such malformations as deviations or bony spines of the nasal septum and hypertrophy of the head of the middle turbinate, surgical measures must be employed. Certain conditions, such as acute coli-bacillary rhinitis occurring during pregnancy, require specific treatment; cure in these is slow and the results are uncertain.

538. Atrophic Rhinitis Treated by Radium.

L. HERBERT and G. A. ROBINSON (*Arch. of Otolaryngol.*, August, 1929, p. 166) review the present knowledge of atrophic rhinitis, and advocate radium treatment. No satisfactory explanation has yet been found for all cases, but the almost routine removal of tonsils and adenoids and the modern treatment of sinusitis have markedly diminished the number of hospital patients. The most characteristic symptom is the offensive odour which is associated with anosmia; the cause of the odour is not clear, but Frese claims that it is due to fatty degeneration of the glandular cells of the nasal mucosa. Up to the present treatment has been unsatisfactory, though the condition has a tendency to disappear after middle life, probably owing to the fibrosis of the nasal mucosa which occurs in old age, and gave the authors the clue to their radium treatment; this would hasten the fibrosis and abolish the foul odour, while leaving the structural atrophy. The first patients treated were subjected to a half erythema dose of gamma radiation; 20 milligrams of radium screened with 0.2 mm. platinum and 1 mm. brass were applied to the lateral nasal wall for ninety minutes on each side. Subsequently an erythema dose was given, two 50 mg. radium tubes screened as before being applied to the lateral nasal walls for sixty minutes. Within a week an inflammatory reaction similar to an acute rhinitis was observed. This reaction subsided in about three weeks, leaving the mucosa more healthy and much less crusty; there was also a marked decrease in the fetor. The authors give notes of five cases, all in young adults, treated by this method with considerable improvement. They emphasize the importance of diagnosing sinusitis if it exists and of treating it surgically. Sinusitis may coexist with a true atrophic rhinitis, and in these cases an operation alone fails to relieve the fetor. The authors believe that operation followed by radium deserves a fair trial in these cases. A complete cure is not claimed for this method, but all the cases treated have been greatly benefited.

539. Malignant Growths in the Throat, Nose, and Ear.

U. CALAMIDA (*Arch. Ital. di Otol., Rhinol. e Laringol.*, October, 1929, p. 620) gives the following statistics of malignant growths treated in the oto-rhino-laryngological department of the Ospedale Maggiore of Milan during the period May 1st, 1908, to December 31st, 1928. Among a total of 26,356 patients, of whom 13,247 were men and 13,109 women, the number of those suffering from malignant growths was 394, or 1.49 per cent. The proportion of men affected was 2.15 per cent., and of women 0.83 per cent. As regards the localization of the tumours, the larynx was the organ most frequently affected (44.5 per cent.), the nasal fossae came next (14.1 per cent.), and then in order of frequency the pharynx (13.6 per cent.), tonsils (10.8 per cent.), oesophagus (7.5 per cent.), ear (4.5 per cent.), maxillary sinus (3.3 per cent.), palate (1.01 per cent.), frontal sinus (0.26 per cent.), and ethmoid sinus (0.26 per cent.). The increase in the number of malignant growths from a minimum of 0.72 per cent. in 1911 to a maximum of 4.15 per cent. in 1926 is probably more apparent than real, and is to be attributed to improvement in diagnosis as the result of biopsies, the gradual increase in the number of statistics, treatment centres, the more careful compilation of statistics, and the increase in the number of persons who reach an advanced age, when new growths are most frequently encountered.

Obstetrics and Gynaecology.

540. Significance of Birth Injuries to the Foetal Skull.

H. HEIDLER (*Wien. klin. Woch.*, September 12th, 1929, p. 1199) draws attention to four examples of foetal skull injuries. In the first case, a breech presentation with delay and difficulty in delivering the head, for which some force was used, an asphyxiated child is born and cannot be revived. Formerly pressure on the cord was blamed, but examination of the skull will show tears of the tentorium cerebelli with haemorrhage into the posterior fossa, causing asphyxia centrally. The second type occurs in the case of a primipara; after a long labour the head is held back still longer by the midwife in an attempt to save the perineum. The child is born blue, but is resuscitated; it remains apathetic, never cries lustily, and dies on the second day of intracranial injury caused by pressure during the passage through the pelvis and accentuated by perineum saving. Thirdly, after a precipitate birth, the child appears healthy, but pines and dies in a few days of intracranial haemorrhage caused by a too quick passage with no time for moulding. Lastly, in a prolonged premature labour resulting in the birth of a partially asphyxiated baby which dies in a few days, the necropsy will show gross changes in the brain, the soft skull not being strong enough to withstand the hardships of birth. According to Heidler, these are typical intracranial birth lesions; they are far commoner than formerly supposed, and point to the necessity for opening the skull at such necropsies. To prevent such accidents, he adds, prolonged labour should be avoided, and gentleness is essential in all operative procedures; care of the perineum must not be carried to excess. Caesarean section should be performed when the pelvis is contracted and in elderly primiparae, and labour should be conducted in hospital and not at home.

541. Krukenberg Tumour of the Ovary.

IN 1896 Krukenberg reported and gave a detailed histological description of a comparatively rare tumour, which he called fibrosarcoma ovarii mucocellulare. He considered it as primarily a sarcoma with carcinomatous elements in its structure. In 1918 Major reported a series of 55 authentic cases which he had collected; he concluded that the tumour was essentially a carcinoma containing sarcomatous elements. R. FALLAS (*Surg., Gynecol. and Obstet.*, November, 1929, p. 638) has found 23 additional cases, including two reported for the first time in this paper. From a study of these he concludes that Krukenberg tumours are essentially a form of carcinoma identified by large mucinous cells often with eccentrically placed nuclei. They are almost, if not quite, invariably secondary to carcinoma elsewhere, and usually to a growth in the gastro-intestinal tract. These neoplasms are generally bilateral; they metastasize early, and are almost invariably fatal. They produce a general enlargement of the ovary, which keeps its general form and is, as a rule, free from adhesions. Ascites is usually associated with the growths. Of special interest is the path of transmission of these tumours from the primary growth in the gastro-intestinal tract to the ovaries, and many theories have been advanced concerning the method of metastasis. Surface infection may occur in some cases; the haematogenous route is also possible; but there is much evidence to make the lymphatic route, suggested by Amann, the most plausible one. This theory presumes that the retrogastric and superior lumbar glands become invaded, thus producing a blockage of the lymphatic stream, and, as a result, a retrograde migration by way of the ovarian lymphatics. The shape of these secondary tumours, which almost invariably corresponds to the original form of the ovary, points to invasion through the medulla rather than the cortex.

542. Puerperal Necrosis and Expulsion of a Myoma.

B. HERZFELD (*Zentralbl. f. Gynäk.*, October 12th, 1929, p. 2592) states that in the puerperium a uterine myoma may undergo involutionary changes with necrosis, and that the necrotic focus of infection whence remote infection may take origin. He relates the case of a 5-para admitted to hospital in labour at term; a myoma the size of the fist was palpable in the lower third of the uterus at the level of the presenting foetal head. Three days after spontaneous delivery of the foetus and placenta an attack of severe abdominal pain occurred with tenderness of the tumour and pyrexia, but yielded to conservative treatment. On the eighth day infarction of the right lung appeared, and on the twenty-eighth day a thrombosis of the right leg was noted. Six days later the intramural myoma, which in consequence of its infection had become detached from its capsule, was expelled by the vagina, and within a fortnight the patient's condition, locally and generally, appeared normal.

Pathology.

543. Storage of Iron after Oral and Subcutaneous Administration.

C. J. POLSON (*Quart. Journ. Med.*, October, 1929, p. 77) records the results of further research controlling previous observations relating to the sequels of the intravenous administration of iron. Four rabbits were given daily doses of 0.5 gram of iron mixed with their food, the preparation used being either undiluted dialysed iron or a 25 per cent. dilution of liquor ferri perchloridi (*B.P.*). The experiments lasted from 172 to 450 days. Eight rabbits were used for the subcutaneous series; five received a single dose of from 0.5 to 1 gram of iron, while the three others received more than one dose, a total of 2 grams, 1 gram, and 0.6 gram respectively. The undiluted dialysed iron was used throughout. The principal site of iron storage, whatever the route of administration, was shown to be the liver. Histologically, at the periphery of the lobules coarse granules of iron were seen gathered around the nuclei in the liver cells, while in other parts of the lobules fewer and smaller granules were also evident. The process of storage was probably identical irrespective of the mode of administration. The caecum and kidneys contained an excess of iron and were probably concerned in its excretion. Excess of iron in the bone marrow was not observed, and there was no undue activity of its cells. The rate of storage varied according to the route. When from 256 to 448 mg. were given by the intravenous route there was between 120 and 184 mg. excess of iron in the liver after intervals of from three to twelve months; following the subcutaneous administration of 1 gram of iron there were 398 mg. excess at the end of eight months, while the oral administration of 90 grams resulted in the storage of only an excess of 81.8 mg. at the end of eight months. The subcutaneous route avoided the danger of intravenous administration—namely, pulmonary embolism.

544. Hypervitaminosis D.

J. A. COLLAZO, B. VARELA, and P. RUBINO (*Wien. Arch. f. innere Med.*, October 25th, 1929, p. 137) have shown, in a series of experiments on white rats, that when fed on MacCollum's rachitic diet to which was added 5 mg. of radiated ergosterin the animals died with symptoms of hypervitaminosis D. Similar but more rapidly poisonous effects resulted from giving the same dose of radiated ergosterin to healthy rats which were fed on a normal diet containing the usual complement of vitamin D. The normal rats died within a week and the rachitic rats in the course of three to four weeks. The animals showed complete calcification of the interdiaphyseal-epiphyseal cartilages of the long bones, with consequent arrest of growth. There was extensive calcification of the walls of the larger arteries with formation of diffuse aneurysms; interstitial nephritis; and the formation of tumours on the stomach wall.

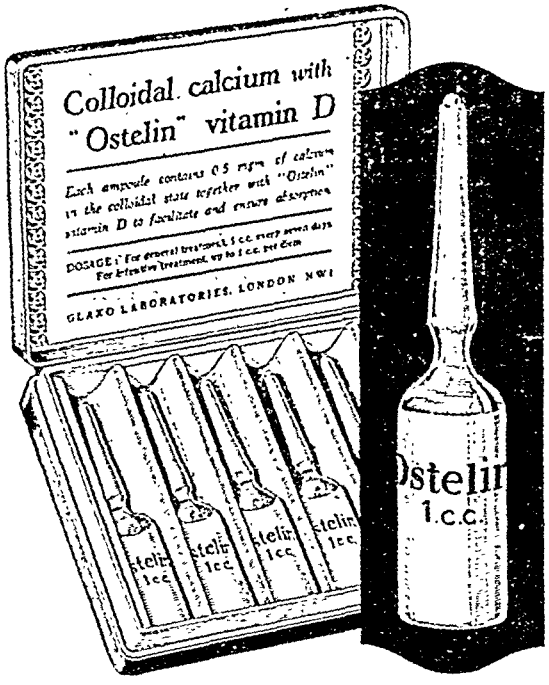
545. Experimental Malaria with Long Latent Period.

W. A. P. SCHÜFFNER, P. C. KORTEWEG, and N. H. SWELLENGREBEL (*Nederl. Tijdschr. v. Geneesk.*, October 5th, 1929, p. 4622) inoculated with malaria eleven volunteers who allowed themselves to be bitten by *Anopheles maculipennis* which had been infected with *Plasmodium vivax*. The inoculations took place between October 30th and November 7th, but the malaria did not develop until between June 26th and August 20th, or after an average interval of eight months. The authors allude to similar experiments carried out by James, whose patients did not develop malaria until six to nine months after they had been bitten by anopheles. Experiments of this kind suggest that the most important part of the annual epidemic of malaria—namely, that before the second half of July—is the result of infection in the previous autumn.

546. Post-operative Bacteriaemia in Malignant Growths.

M. EINAUDI (*Giorn. di Batteriol. e Immunol.*, September, 1929, p. 884) investigated the presence of post-operative bacteriaemia for malignant growths by the following method. Of 12 c.cm. removed from a vein of the elbow, 5 c.cm. were inoculated into 250 to 300 c.cm. of broth, 3 to 4 c.cm. on agar plates, and the remainder on the Tarozzi-Noguchi medium or in Kollrath's double tube for anaerobes. The blood was taken immediately after the operation, or after an interval of half an hour, 7, 24, or 48 hours. Einaudi concludes that post-operative bacteriaemia is not frequent; when it does occur, it appears during the first few hours after the operation. Of 340 cases studied it was usually transient in 26, or 7.64 per cent., disappearing within 24 hours, and not constituting an unfavourable symptom. No relation was found to exist between post-operative bacteriaemia and the clinical course.

CHILBLAINS



Colloidal Calcium
with Ostelin vitamin D

"I used the latter (Colloidal Calcium Ampoules) at once in treatment of acute chilblains, with immediate improvement—3 injections alternate days cleared up the condition and the injections will now be given weekly."—. . . .M.B., Ch.B., 21/11/29.

CLINICAL INDICATION. In vasomotor skin affections, chilblains, chilblain circulation, urticaria in gross nutritional failure occurring in debility diseases, and also in delayed union of fracture, these Ampoules have proved of value.

ESTABLISHED 1793

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and trouble-free, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading aurists of world-wide reputation.—Mr. Dent will be happy to send full particulars and reports on request.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for *hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion* bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a *Department for Diathermy and High Frequency treatment. It also contains Laboratories for* biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. *On the North-West side of the* Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM (333 Beds).

SENIOR ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Senior Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Applicants must have held resident hospital and sanatorium appointments, and have had practical experience in the diagnosis and modern methods of treatment of tuberculosis; practical experience in radiology is desirable.

Salary £500 per annum, with board, residence, and laundry in addition.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope, "Medical Officer, Baguley Sanatorium," must be addressed to the undersigned only, and not to members of the Committee or Council, and must reach him not later than Monday, December 30th.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of his office, to take charge in the absence of the Medical Superintendent, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
T. E. WARBRECK HOWELL,
Town Clerk.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM (333 Beds).

ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Preference will be given to applicants with previous Hospital experience; some experience of bacteriology or pathology is desirable.

Salary £400 per annum, with board, residence, and laundry in addition.

The appointment is made in the first instance for a period of twelve months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope, "Medical Officer, Baguley Sanatorium," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must reach him not later than Monday, January 6th, 1930.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of the office, to contribute to the Corporation Superannuation Fund and to execute the Deed of Service. Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
T. E. WARBRECK HOWELL,
Town Clerk.

Town Hall, Manchester. December 6th, 1929.

Metropolitan Asylums Board.

Applications are invited for the appointment of JUNIOR ASSISTANT MEDICAL OFFICER at GROVE PARK HOSPITAL, LEE, S.E.12 (322 beds) for Adult (male and female) cases of Tuberculosis. Most of the accommodation is for advanced pulmonary cases, but there is a certain number of beds for surgical cases, and some experience in surgery and orthopædics is desirable. There is no accommodation at the Hospital for a married officer. Preference will be given to candidates under 30 years of age. Salary £300 per annum. There are three other Medical Officers on the staff.

The candidate appointed will be required to reside in the Institution and to pay for board, lodging, and washing at the rate fixed from time to time by the Board's Finance Committee. At present the rate is £150 per annum.

Application to be made not later than 10 a.m. on Saturday, December 28th, on form obtainable from the Clerk, Metropolitan Asylums Board, Victoria Embankment, E.C.4, by forwarding stamped addressed foolscap envelope.

ALLAN POWELL,
Clerk to the Board.

Dec 5th, 1929

County Borough of Brighton.

RESIDENT MEDICAL OFFICER at the Borough Infectious Disease Hospital and Sanatorium.

The Council invite applications for the above appointment from duly qualified unmarried male Medical Practitioners.

The salary will be at the rate of £350 per annum, together with board and lodging at the Borough Sanatorium. Preference will be given to candidates entering the Public Health Service.

Forms of application and particulars of the duties to be performed, and of the conditions upon which the appointment will be made, may be obtained on application to the undersigned.

Applications (with copies of three recent testimonials enclosed), endorsed "Application for the Appointment of Resident Medical Officer," must be delivered at my office before 10 o'clock in the forenoon on Tuesday, December 24th.

Canvassing members of the Council, either directly or indirectly, will disqualify any applicant for the position.

JAS. H. ROTHWELL,
Town Clerk.

Town Hall, Brighton.
December 2nd, 1929.

West Suffolk General Hospital,

BURY ST. EDMUNDS. (103 Beds.)

Applications are invited for the post of HOUSE SURGEON (male), which will be vacant early in January. Salary £150 per annum, with board, residence, and laundry. Applicants must be fully qualified and registered.

Applications, giving particulars of experience and enclosing three recent testimonials, to be sent to the undersigned.

E. E. HARDWICKE,
Secretary.

December 9th, 1929.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and form of application may be obtained from the Under-Secretar of State for India, Military Department, India Offic London, S.W.1. Applications should be submitted soon as possible. The Selection Committee will me early in January to make nominations, and the selecte candidates will be required to attend a course instruction commencing on or about the 1st February, 193

Department of Health for SCOTLAND.

BACTERIOLOGY AND MEDICAL STATISTICS.

APPOINTMENT OF MEDICAL OFFICERS.

The Department of Health for Scotland are prepared to receive applications from registered Medical Practitioners for two posts as Medical Officer.

Experience.—Applicants must have either—

(a) expert knowledge of bacteriology—experience in hospital administration will be an additional qualification,

or

(b) training and experience in medical statistics.

Age.—Must not be over 45 years.

Salary.—£600 per annum, rising by annual increments of £25 to £850 per annum, then by annual increments of £50 to £1,000 per annum. Cost of living bonus will be payable in addition—the bonus on £600 at present £176 and on £1,000 being £286.

Duties.—Medical Officers appointed will be required to devote their full time to the public service, and to perform such duties as may be assigned to them by the Department from time to time.

Further particulars and forms of application may be obtained from the Establishment Officer, Department of Health for Scotland, 125, George Street, Edinburgh. Letters applying for forms of application should have the words "Medical Officer," boldly written in the top left-hand corner of the envelope. No application will be considered if received after January 1st, 1930.

Applications and enquiries to be made to the undersigned.

G. HURFORD,
December 9th, 1929. House Gov. & Sec.

The General Hospital,
BIRMINGHAM.

Applications are invited for the post of STIPENDIARY ANÆSTHETIST from qualified Medical Practitioners experienced in the administration of anæsthetics.

The person appointed will be required to attend daily from 9 a.m. to 2 p.m. Salary £250, with lunch.

Applications should be sent to the undersigned by December 30th.

A. H. LEANEY,
December 7th, 1929 House Governor.

Royal Free Hospital,
Gray's Inn Road, W.C.1.

Applications are invited for CLINICAL ASSISTANTS (Senior and Junior) in the Medical, Surgical and all Special Departments. Intending candidates should submit applications, stating age and qualifications, to the undersigned on or before January 4th, 1930.

Preference will be given to former Students of the Hospital.

REGINALD R. GARRATT, Secretary.

Parish of Portsmouth.

FIRST ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians of the above-named Parish invite applications for the appointment of a First Assistant Resident Medical Officer for the SAINT MARY'S HOSPITAL, ST. MARY'S INSTITUTION, and CHILDREN'S HOME.

The appointment will be made for a period not exceeding three years, and will be subject to one month's notice on either side.

Salary £330 per annum, with furnished apartments, rations, and other allowances.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, for which purpose the value of the emoluments has been fixed at £125 per annum.

Candidates must be single gentlemen, duly registered, possess the qualifications required by the Orders of the Ministry of Health, and preference will be given to candidates having a knowledge of the treatment of Mental Diseases, and who have experience in Surgical work. The Hospital affords plenty of scope for major and minor surgery.

A Resident Medical Superintendent is in attendance.

Applications to be made on printed forms which may be obtained at this office, accompanied by not more than three recent testimonials, and a description of the diplomas, certificates of degrees, licences, and other instruments held by the candidates, and must be returned to me by Monday, December 30th.

By Order,
Guardians' Offices, St. Michael's Road, Portsmouth. W. E. GODFREY, Clerk to the Guardians.
December 5th, 1929.

APPOINTMENTS.—Contd.

Leicester Royal Infirmary.

HONORARY PHYSICIAN.

A vacancy for an Honorary Physician will arise in February, consequent upon the retirement, under the rules, of Dr. Astley V. Clarke, Senior Physician. Applications are invited for the post. The only candidates eligible are those who have held the position of Honorary Assistant Physician to Leicester Royal Infirmary.

The present Senior Honorary Assistant Physician is a candidate.

HONORARY ASSISTANT PHYSICIAN.

Should the above vacancy be filled by one of the present Honorary Assistant Physicians, there will be a vacancy for an Honorary Assistant Physician. Candidates must be Graduates in Medicine of one of the Universities of the United Kingdom of Ireland, and duly registered. Fifty guineas annually is granted by the Board for out-of-pocket expenses. Applications (in the latter case accompanied by 100 copies of recent testimonials) to reach the undersigned by Tuesday, January 14th, 1930.

HONORARY SURGEON.

A vacancy for an Honorary Surgeon will arise in *February, consequent upon the retirement*, under the rules, of Mr. J. S. Sloane. Applications are invited for the post. The only candidates eligible are those who have held the post of Honorary Assistant Surgeon to Leicester Royal Infirmary.

The present Senior Honorary Assistant Surgeon is a candidate.

HONORARY ASSISTANT SURGEON.

Should the above vacancy be filled by one of the present Honorary Assistant Surgeons, there will be a vacancy for an Honorary Assistant Surgeon. Candidates must be Fellows or Members by examination of the Royal College of Surgeons of England, or Graduates in Surgery of the United Kingdom or Ireland. Fifty guineas annually is granted by the Board for out-of-pocket expenses. Applications (in the latter case accompanied by 100 copies of recent testimonials) to reach the undersigned by Tuesday, January 14th, 1930.

It is proposed that the successful candidate, in addition, shall be in charge in the Orthopædic Department, and he must have had experience in that branch of Surgery.

Canvassing in any of the appointments is not allowed.

HARRY JOHNSON,
House Governor and Secretary.

Hospital for Invalid and CRIPPLED CHILDREN,
119, Balaam St, Plaistow, E.

Applications are invited for the post of HOUSE PHYSICIAN (woman) to the above Hospital for a period of six months. Time available for Post-Graduate study. Salary at the rate of £50 per annum, together with board, maintenance, and laundry. Applications, together with particulars of qualifications and testimonials, must be sent at once to the undersigned.

R. I. HOWARD, Secretary.

Malayan Medical Service.

A vacancy exists at present for an ANÆSTHETIST in the GENERAL HOSPITAL, SINGAPORE.

Qualifications.—Applicants must be British subjects of European parentage and under 35 years of age. Experience in the administration of anæsthetics for a period of at least two years is essential.

Salary.—$600 a month (£810 per annum, at *exchange Straits $1=2s. 4d.*), *rising by annual* increments of $25 a month (£25 per annum) to $800 a month (£1,120 per annum). In addition *to salary*, there is at present a non-pensionable temporary allowance of 10 per cent. of salary to unmarried officers, and 20 per cent. to married officers.

Conditions of Service.—*The selected candidate* will be on agreement for three years in the first instance. If the appointment is continued he will be placed on the permanent and pensionable establishment, his previous service counting as part of his permanent service for the purpose of calculating leave and pension.

Quarters.—*Quarters, if available*, are provided at a rental which in no case exceeds 5 per cent. of the officer's salary.

Passages.—Free first-class passages are provided.

Private Practice.—Private practice is not allowed, but consultation with another practitioner is permitted.

Date of Sailing.—The selected candidate will be required to assume duty in Singapore in May, 1930.

Further particulars and forms of application may be obtained, on application in writing, *from the Private Secretary (Appointments)*, Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

Nottinghamshire County Council
EAST RETFORD CORPORATION.
EAST RETFORD RURAL DISTRICT COUNCIL.

APPOINTMENT OF JOINT MEDICAL OFFICER.

The Nottingham-shire County Council, the East Retford Corporation, *and the East Retford* Rural District Council jointly invite applications from duly qualified and registered Medical Practitioners for the whole-time *appointment of a Medical Officer* to act as—

(*a*) ASSISTANT MEDICAL OFFICER of the County Council;

(*b*) MEDICAL OFFICER OF HEALTH, SCHOOL MEDICAL OFFICER, and CERTIFYING OFFICER for the purposes of Section 55 of the Education Act, 1921 (Defective and Epileptic Children), and Section 31 (1) of the Mental Deficiency Act, 1913, of the Corporation of East Retford;

(*c*) MEDICAL OFFICER OF HEALTH to the East Retford Rural District Council.

The salary attaching to the position will be £750 per annum (with reasonable travelling and subsistence allowances), rising after two years' *satisfactory service by two annual increments of* £25 each to a maximum of £800 per annum; and the person appointed will be required to reside within a radius of two miles from the Market Square, East Retford.

Applicants must have had at least three years' professional experience since qualifying, be conversant by experience in the duties of a Medical Officer of Health and School Medical Officer, and also possess a Diploma in Public Health. Experience in Rifraction Work and the examination of Defective Children is essential.

The appointment will be terminable on three months' notice, and be subject to the approval of the Ministry of Health and the Board of Education, and also to the provisions of the Sanitary Officers Order, 1926.

Form of application and conditions of appointment can be obtained at my office, and must be forwarded to me not later than December 30th, 1929.

K. TWEEDALE MEADY,
Clerk of the Nottingham-shire
Shire Hall, County Council.
Nottingham, Dec., 1929.

Swansea County Borough.

MALE ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite applications from duly qualified Medical Practitioners for the post of Male Assistant Medical Officer to assist with the Medical Services of the Corporation.

Hospital resident and special experience of refraction and ear, nose, and throat work, school medical service, and maternity and child [illegible] trable; the D.P.H. [illegible] the foregoing, is [illegible] er annum, subject [illegible] of Education and [illegible] ; [illegible] rms, which can be obtained from Dr. Thomas Evans, Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than December 31st.

Lancashire County Council.
SCHOOL MEDICAL AND CHILD WELFARE DEPARTMENT.

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER.

The Lancashire County Council invites applications from registered Medical Practitioners for *the post of Assistant County Medical Officer.*

Applicants must not be over 35 years of age, and must possess the Diploma of Public Health.

The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare Acts; general Public Health work; and such other duties as may from time to time be imposed by the County Council.

The person appointed will be required to devote his whole time to the service of the County Council. The salary will be £599 a year, rising (subject to satisfactory service) by annual increments of £50 to a maximum of £1,049 a year, together with first-class railway fares and other reasonable expenses.

The person appointed will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained, together with further particulars, from the County Medical Officer of Health, School Medical and Child Welfare Department County Offices, Preston, to whom the completed forms should be returned not later than Tuesday, December 31st, 1929. All communications must be endorsed "Assistant County Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

GEORGE ETHERTON,
Clerk of the County Council.
County Offices, Preston,
December, 1929.

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. SHEFFIELD.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500. Panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £55 p.a. Premium £2,250. Ill health reason for sale.
2. WILTSHIRE.—Very pleasant village, in beautiful surroundings, and within easy reach of good town. Income last year £1,100. Panel of 445. Fees 2/6 to 21/-. Exceptionally picturesque house, with 3 reception, 4 bedrooms, 2 maids' rooms, etc. Electric light and gas. Garage for 2 cars. Half an acre of garden. Price for freehold £2,000. Premium £1,400.
3. EASTERN COUNTIES.—LARGE TOWN.—Sound good middle and working-class PRACTICE, producing last year nearly £1,900, including panel of 2,300. Fees 3/6 to 10/6, medicine extra. No midwifery. Specially built house, easily run and with every modern convenience. Contains 2 reception, 5 to 6 bedrooms, etc., and good professional accommodation. Garage. Garden. Price for freehold £3,000, half on mortgage. Premium 1½ years' purchase.
4. KENT.—*Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast.* Income for past 12 months £1,185, and increasing. Visit 5/- to 21/-. Panel of about 380. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' pur.
5. NORTH MIDLANDS.—Well-established mixed class PRACTICE situated in a town of nearly 20,000 inhabitants, with large surrounding district. Cash receipts about £2,000 p.a., including club of £250 and panel of 1,000. Expenses light. Good house, with ample accommodation. Would be let or sold. Prem. for immediate sale £2,000.
6. PARTNERSHIP.—SOUTH-WEST.—(Within 100 miles of London).—Partner required, experienced in surgery, to take over a fourth, third, or half share in a very old-established Practice in a desirable country town. Income over £4,200 p.a. (this year to end of Oct. £4,455), including appts. £300 and panel of 1,950. Visits up to 31/6. Good house, with ample accommodation. Price, freehold, £2,000. Prem. for share 2 years' purchase. Up-to-date Cott. Resp.
7. EASTERN COUNTIES.—Very attractive Village within 100 miles of *London*. Old-established, practically unopposed, mixed-class PRACTICE, averaging about £1,200 p.a. Panel of over 700. Advice and medicine 3/6 to 5/-. Visits 5/- to 10/6, a few at 21/-. Large detached house, in perfect order and with every modern convenience. Price for freehold £1,600. Premium £1,800.
8. PARTNERSHIP. — ESSEX. — *(Within 50 miles of London).* — Third Partner required in very old-established rapidly increasing Practice in small country town. Cash receipts for past three years average £3,755 (last year £4,176), including panel of 2,200 and appts. Third share is for disposal, opposition slight. Visits 5/- to 21/-. Good house, professional accommodation, 2 reception, 4 bedrooms, bathroom, etc. Large garden. Garage. Rent £60. Premium 2 years' purchase. Educational facilities and sport.
9. WITHIN TWENTY MILES OF LONDON.—Old-established good mixed-class PRACTICE, in attractive residential district. Receipts average £1,000 p.a. Panel of nearly £500 and appts. worth £60. Visits 3/6 to 21/-. Very nice house, with all modern conveniences and half acre of garden. Price for freehold £1,800. Premium £1,400.
10. ESSEX.—(Within 15 miles of London).—Old-established unopposed and increasing PRACTICE, in pretty country district. Income last year over £1,100, including Union £90 and panel £432. Comfortable House, with ample accommodation (water laid on) and large garden. Rent £70 p.a. on lease. Premium £1,650. Ill health reason for sale.
11. HOME COUNTIES.—Within few miles of large town.—Old-established unopposed and increasing PRACTICE, in pleasant district, worth over £3,000 p.a., including panel, with mileage, producing about £1,000 and appts £260. Visits 3/6 to 10/6, medicine usually extra. Very little midwifery. *Good house (7 bedrooms, etc.),* garden, garage. Price, freehold, £2,000. Premium 1½ years' purchase.
12. X-RAY AND ELECTRO-THERAPEUTIC CONNECTION, in popular South Coast Watering-place. Receipts, which are rapidly increasing and include resident patients for treatment, amounted last year to nearly £800. Large house and garden. Price, freehold, £6,500. Premium 1½ years' purchase. Opposition very slight and the investment offers considerable scope.
13. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, *medicine extra.* Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
14. ESSEX.—POPULAR COAST TOWN.—Small easily worked PRACTICE, offering good scope, as district developing. Income last year £530. Panel of 200. Fees 2/6 to 7/6. House contains 2 reception, 3 bedrooms, etc. Garden. For sale or on rental. Premium £750, part down and balance instalments.
15. LONDON, NORTH-WEST.—RESIDENTIAL SUBURB.—PARTNERSHIP. —A one-fourth share (up to one-half in 12 months) in a very old-established non-panel and non-dispensing better-class Practice. Average income £6,000. Fees 7/6 to 10/6. Large double-fronted house available. Senior Partner retiring. Premium 2 years' purchase.
16. SOUTH WALES.—Seaside Resort.—*Old-established* mixed-class PRACTICE in favourite locality. Receipts for past 12 months £1,400, including panel of 697. Visits 3/6 to 21/-. Convenient house, with 2 reception, 4—6 bedrooms, and professional rooms, etc. Rent on lease £80 p.a. Good sport and schools. Prem. 1½ yrs.' purchase.
17. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,500, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,500, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.
18. CROYDON AREA.—PARTNERSHIP.—A two-fifths share to commence with in an old-established middle-class Practice. Income £2,750. Panel of 988. Fees 3/6 to 10/6. Convenient house on lease. Rent £80 p.a. Premium 2 years' purchase.
19. PARTNERSHIP.—FAVOURITE SOUTH COAST WATERING-PLACE.—Third Partner required in very old-established mixed-class and increasing Practice, the income of which for last financial year amounted to over £4,000, including panel of 3,300 and appts. producing £2,500. Third share offered to commence with, with prospect up to one half. Visits 3/6 to 10/6. Suitable house obtainable. Premium 2 years' purchase. Short preliminary assistantship offered.
20. PARTNERSHIP.—CHESHIRE.—Within a few miles of a large town. —In a pleasant residential district (pop. over 7,000), the half share of a very old-estab. Practice worth about £4,000 p.a. Patients all classes. Suitable house available on rental. Premium 2 years' purchase, part by instalments. Good society and schools.
21. ESSEX.—HOSPITAL TOWN.—PARTNERSHIP.—A one-fifth share, to commence with, in a well-established mixed-class Practice producing about £8,000 p.a., including large panel. Fees 3/6 to 21/-. Good house, with large garden, for sale; part on mortgage. Premium 2 years' purchase, payable £2,000 down and balance by instalments.
22. SOUTH MIDLANDS.—FAVOURITE RESIDENTIAL TOWN.—PARTNERSHIP.—A one-fifth share in a very old-estab. good mixed-class non-dispensing Practice. Income last year over £5,500, and very rapidly increasing. Panel of 1,700. Fees 5/- to 10/6. Suitable house available. Excellent schools, sport, and social life. Premium £2,000.
23. BEDS.—PARTNERSHIP.—Owing to the retirement through ill health of one of four partners, a share producing about £1,300 p.a. is for disposal in a sound middle-class Practice, in attractive district. Panel of over 3,500. Suitable house, with ample accommodation. Rent £60 p.a. on lease. Good sport and schools. Premium 2 years' *purchase, part by instals.*
24. HOME COUNTIES.—COUNTY TOWN.—PARTNERSHIP.—A one-third share, owing to the retirement through ill health of one of two partners, is offered in an old-established Practice. Gross cash receipts about £3,600 p.a. Fees 3/6 to 21/-. Very good house can be rented. Premium 2 years' purchase.
25. SOMERSET.—Near Hospital Town, in very pleasant residential district, an old-established unopposed Country PRACTICE averaging over £950 p.a., including panel (producing about £400 p.a., with mileage) and appts. Visits 3/6 to 21/-. Railway station in place. Nice house (5 bedrooms, dressing and bathroom, etc., garden). Price, freehold, £1,500, of which £1,000 on mortgage. Premium £1,400.
25. LONDON, EAST.—(Within 1 mile of Liverpool Street).—Old-established PRACTICE in thickly populated district worth last year £848, including panel of 520. Small house (surgery, waiting room, dispensary, lounge sitting room, 2 bedrooms, bathroom, etc.). Rent on lease £60 p.a. Premium £1,400, or near offer to include fitted carpets, linoleum, and curtains.
27. MANCHESTER.—Rapidly growing Suburb within 5 miles of the City.—Old-established mainly middle-class PRACTICE, producing a steady average income of £2,000. Panel of nearly 1,400. Fees 3/6 to 10/6. Large house and garden. Price, freehold, £2,500, or would be let on lease at £120 p.a. *Premium £3,500.*
28. PARTNERSHIP.—Pleasant Seaside Resort within 40 miles of London.—A third Partner required in very old established mixed class Practice worth about £5,000 p.a. (this year it is anticipated receipts will be £5,500), including panel about 1,800. Visits 5/- to £1 1s. Only 20 to 30 midwifery cases yearly. Prospect of being appointed on Hospital staff within reasonable time. Suitable flat available or house to be obtained. Premium 2 years' purchase.
29. PARTNERSHIP. — WITHIN 50 MILES OF LONDON. — A fourth Partner is required to take over a share, representing about £1,300 p.a., in an exceptionally sound good middle-class Practice situated in attractive residential district. Panel of over £3,500. Nice house, with 3 reception, 5 bedrooms, etc. Garden. Garage. Rent £60 p.a. on lease. Good sport and schools. Premium 2 years' purchase, part by instalments.
30. PARTNERSHIP.—NORTH WALES.—(Pretty district on Borders of Cheshire)—The THIRD or HALF SHARE *of old established PRACTICE* worth over £4,000 p.a., and consisting mainly of panel (producing over £2,100) and appts. worth about £1,600. Expenses light. Suitable house available if half share taken (net rent £50 p.a.), otherwise inexpensive rooms. Premium for share 1½ years' purchase.
31. SUFFOLK.—COUNTRY PRACTICE, near sea.—One-third share in good *mixed-class* Practice averaging about £3,300 p.a., *including panel* of 1,300. Suitable house available. Premium 2 years' purchase. Preliminary assistantship essential.

Full Schedule of Terms and Conditions will be forwarded on application.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair { 1782 / 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

PHARMACEUTICAL SPECIALISTS TO THE MEDICAL PROFESSION
MANCHESTER.

The Medical Profession when prescribing Liquor Carbonis Detergens SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

ASTHENIA and the Fatigue Syndrome

are usually conditions in which a definite pathology cannot be demonstrated.

Hormotone
BRAND

has proved its value in treatment, through its action in:

Stimulating cell metabolism,

Increasing the respiratory exchange,

and

Raising to normal the low blood pressure usually attendant upon such conditions.

Dose: One or two tablets three times daily before meals.

Dimol

in Enteric Epidemicity

Causation is always difficult, and often impossible to discover, but it seems a reasonable procedure, in epidemic areas, to assist prevention by the use of an intestinal bactericide. Dimol is non-toxic to any part of the alimentary mucosa, yet *one grain* has a bactericidal potency for cultures of B. typhosus equal to thirty-five times that weight of pure phenol.

The Dimol Laboratories are prepared to demonstrate to any properly constituted committee of the Medical Profession that a pure culture of this bacillus can be swallowed, and the germs destroyed in the stomach by the action of Dimol Pulverettes, taken immediately after the culture.

The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to the

'VERAMON' in PAIN

An important feature in the female reproductive system is Pain, and an analgesic which affords rapid and well-sustained relief in *Labour and Post-partum Pains*, without paralysis of the muscular contractions or toxic by-effects, is of pronounced value.

Such an analgesic is

Veramon
TRADE MARK

and abundant clinical evidence points to its effectiveness in *pain arising from no matter what cause.*

In conditions of *Painful Menstruation* it affords relief without interference with the ordinary duties of the patient.

The wide field of its usefulness embraces such diverse conditions as the symptomatic treatment of *Simple Headache and Inoperable Carcinoma.*

Clinical reports also refer to its value in the extreme pains of *Biliary and Renal Calculus*, and although its pain-relieving properties are so marked, it is perfectly safe—in therapeutic doses.

Tubes of 10 and 20 Tablets (grs. 6). Bottles of 100, 250, and 500.

Dose: 6—12 grains, according to severity of pain.

AUSTIN 16 H.P. SIX-CYLINDER

£425

This is undoubtedly the Ideal Car for the Medical Man

A Selection from our List of SPECIAL OFFERS

AUSTIN 16 h.p. M.E. All-purpose Fabric Coupé Shopsoiled. New ...	£65 below list **£360**
AUSTIN 16 h.p. M.E. Four-Fold Head Fabric Coupé New. Shopsoiled only ..	£105 below list **£345**
HUMBER 16.50 h.p. M.E. All-purpose, Weymann Coupé. Shopsoiled. New	£75 below list **£450**
SUNBEAM 16 h.p. M.E. Weymann Three-quarter Coupé. Used for demonstration only	£137 below list **£575**
SUNBEAM 16 h.p. All-purpose Coupé Cabriolet M.E. Coachbuilt. Shopsoiled	£120 below list **£625**
SUNBEAM 20 h.p. M.E. Four-Light Weymann Saloon	£135 below list **£750**
CITROEN 2½ litre Coachbuilt Safety Saloon, 1929. Used only for demonstration	£25 below list **£295**

In the "all-closed" position it has the neat appearance of a normal coupé, and is ideal for Town work.

The head can very quickly be made to assume three other positions, *i.e.*: (1) all open (as shown on the left); (2) roof open only; (3) rear quarter open only (as on the right).

The interior will accommodate four passengers comfortably, and a further two can be carried in a dickey seat which can be fitted.

Workmanship, material, and finish are of the very best throughout, and the car as illustrated, on an Austin 16 h.p. 6-cylinder chassis, is a remarkably sound investment.

Any car in which you are interested will be driven to your address for inspection at any time, without obligation.

Famous as The Food of Royal Infants

also for invalids, the aged, and all persons of weak digestion

ROBB'S NURSERY BISCUITS have no equal. Easy of assimilation, a nourishing and sustaining diet, its appetising flavour is greatly appreciated by both young and old. Very welcome as a substitute for the ordinary bread-and-milk diet. Can also be lightly baked, with eggs and milk, to supply a delicious custard pudding

Robb's NURSERY BISCUITS

Highly recommended by eminent Accoucheurs and Physicians throughout the world as the most reliable food for Infants over six or seven months.

ROBB'S NURSERY BISCUIT POWDER is recommended when a feeding bottle is to be used, also as a diet for invalids.

ROBB'S DIGESTIVE RUSKS, TOPS and BOTTOMS, GINGER NUTS, and CHARCOAL BISCUITS are specially recommended for invalids and convalescents.

Send for large free sample and descriptive booklet, etc.

Alex Robb & Co Ltd (Dept. 6), NURSERY BISCUIT FACTORY, ATKINS ROAD, CLAPHAM PARK, LONDON, S.W.12.

A *new* appetising BROMIDE and VEGETABLE YEAST product

Brosedan is an agreeable liquid preparation of Bromide and Vegetable Yeast possessing an appetising taste and a high proportion of the Yeast Vitamins. It is most economical in a course of salt-free diet, and can be employed alone or with additional condiments.

Indications: Brosedan is an excellent sedative in all cases of neurasthenia, nervous sleeplessness, neuralgia, physical excitement, hallucinations, and in the treatment of epilepsy.

Samples and Literature will be sent free to the Medical Profession on request to Messrs. COATES & COOPER, Importers and Exporters of Medical and Pharmaceutical Specialities, 41, Great Tower Street, London, E.C.3.

In all cases of auto-intoxication

Diabetes, rheumatism, gout, sciatica, lumbago, neuritis and many other similar diseases have been found to have their origin in auto-intoxication, which gives rise to acidosis. ¶ The speedy and thorough evacuations induced by Sal Hepatica expel all auto-intoxicants from the system, while the blood and urine is rendered alkaline. ¶ Sal Hepatica stimulates the biliary flow, thereby relieving hepatic congestion, and restores the daily habit of defecation by natural means. It is non-habit-forming, non-irritant and entirely painless in its action. Sal Hepatica is only advertised to the medical profession.

"Sal Hepatica"

Intestinal Disinfection

ALIMENTARY TOXÆMIA AND NEURASTHENIA

NEURASTHENIA is no doubt a comprehensive term which includes several affections of different ætiology.

In many of the cases alimentary toxæmia plays a considerable part; the digestion is upset and flatulence is frequent, the bowels are fickle in their action, and the indican and ethereal sulphates in the urine are markedly increased—sure signs of putrefactive changes in the bowel.

In this class of cases intestinal disinfection is one of the principal lines of treatment to be adopted, and for this purpose nothing surpasses the use of Kerol Capsules.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. Vichy-Celestins, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

Messrs. KAYLENE, LTD. April 17th, 1929.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

WRIGHT'S LYSOL

Emphasise "WRIGHT'S" to your patients

To tell them to ask for Lysol is not enough, for you know that there are Lysols available which are caustic and irritate the skin. Wright's Lysol is safe. It is British owned and British made — analytically controlled by the Rideal-Walker test which guarantees unvarying purity. It contains no free alkali, cannot injure delicate membranes and gives certain results.

The medical profession has endorsed the use of Wright's Lysol for the past seven years. Your patients should know the safety that is in the name.

British Created and British Made by the makers of the famous Wright's Coal Tar Soap.

WHY HOVIS MATTERS

Largest VITAMIN B Content

Important Conclusions

The question as to what form of bread provides the essential Vitamin B most completely and economically has now been settled by independent experiments.

It is shown that in 100 g. dried bread the content of Vitamin B in milling products and yeast is:

White Bread	200
Wholemeal Bread	1,450
HOVIS Germ Bread	2,600

That the presence of the Vitamin is essential actively to promote health in adults and sturdy growth in children, is generally accepted from continued observation.

Wheat is rich in Vitamin B and the germ is the richest part.

HOVIS is made from the white flour, with the germ added. This gives HOVIS its pre-eminent position as a basic ration.

You obtain—as demonstrated by series of experiments by independent investigators—a greater active nutritive value from HOVIS than from any other cereal.

You need a smaller amount of HOVIS than any other bread for the proportion of nourishment received. This is a matter of very practical importance, especially where, as in so many homes and institutions, bread of necessity forms a large part of the daily diet. With children especially, a far larger amount of Vitamin B is supplied to them when fed on HOVIS.

One slice of HOVIS weighing 1 oz. contains as much Vitamin as 2 oz. of Wholemeal, and as 5 to 6 g. of fresh yeast.

Everybody likes it—another practical consideration, especially with children, and it is digested nearly as easily as white bread, and much more so than wholemeal.

VITAD PALATINOIDS

¶ VITAD is the unsaponifiable fraction of Cod-Liver Oil containing in a high concentration Vitamins A and D.

¶ While presenting practically the full medicinal properties of Cod-Liver Oil, it is free from the nauseating oily fraction. Being exhibited as a Palatinoid, it is protected by the hermetically sealed non-actinic covering from all chance of oxidation and light action, thus ensuring a standard dose at all times.

¶ Palatinoid Vitad is put up in bottles of 25 and 100, and in two strengths:

m. 1½ for Children
m. 3 for Adults.

Two palatinoids respectively represent the full daily dose of Vitamins A and D.

"The Patient looked a different being"*

★
Dg. 3.—In a case of chronic gastritis and gastroptosis "I can say the patient looked a different being when she had finished the tin. In my opinion you have a very efficient remedy."
—, M.R.C.S., L.R.C.P.

D.18.—"I believe that Bemax stimulated my digestion, it certainly gave a feeling of 'well-being' and fitness."
—, M.D., F.R.C.S.

FOR Constipation, Debility, Gastric Disturbances, Intestinal Toxæmia, etc., Bemax is giving excellent results. In fact, whenever the ailment is traceable to 'B' Vitamin deficiency, Bemax is an invaluable remedy. A tablespoonful a day supplies all the vitamin B required by an adult, together with Vitamins A and E and valuable mineral salts.

Over 34,000 members of the medical profession in Great Britain have already applied for Bemax for personal trial. We shall be happy to send a free supply to any medical man interested on receipt of his professional card.

BEMAX

The Most Concentrated Extract of Natural Vitamin B

THE BEMAX LABORATORIES, 38, DANEMERE STREET, LONDON, S.W.15

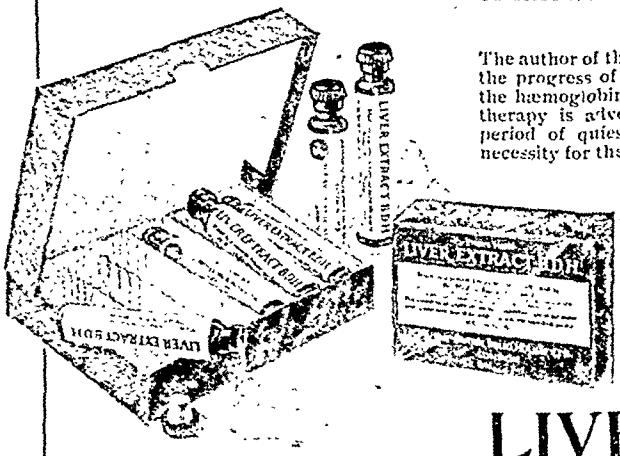
For the treatment of

Pernicious Anæmia

"It is important that only liver extracts of known activity should be used."

Lancet, Nov. 30th, 1929, p. 1115.

The author of the above statement observes that, not infrequently, the progress of a patient under liver treatment is arrested when the hæmoglobin percentage approximates to 60. Intensive liver therapy is advocated, temporarily, in order to overcome this period of quiescence, and special emphasis is laid upon the necessity for the use of high-grade liver extracts only.



Liver Extract B.D.H. is made by a special process tested and found efficient by The Medical Research Council, and results of exhaustive clinical trials show it to be remarkably active in blood regeneration.

Liver Extract B.D.H. is a palatable powder; it can be taken by the most fastidious of patients either as a soup or sprinkled dry on toast or biscuits.

VITAMALT

RICH IN ESSENTIAL VITAMINS A, B, C AND D.

Vitamins have gone beyond the experimental stage. Modern research work has demonstrated the *vital necessity* for the various vitamins against infective processes, for rachitic conditions, and deficiency diseases, and in providing for the human system a very necessary adjunct in the maintenance of good health. Vitamalt is the only preparation of its kind which is guaranteed to contain Vitamins A, B, C and D, and it has been demonstrated that Vitamalt assists the metabolic processes, promoting normal development of *bone and tissue*, and ensuring correct assimilation of calcium. In Vitamalt, vitamins are incorporated in the proportion which science has indicated as the most suitable for average conditions.

The most easily digested of all Milks -

Libby's Milk is the safe milk—safe for Baby all the year round. Sterilized, evaporated, "homogenized," and available in the sealed container so that it is always scientifically clean. The sounder, better health which Libby's gives means a more contented, happier Baby. Libby's Evaporated Milk is as easily digested as Mother's Milk. The sterilization makes the curds soft and flocculent, and as the milk is also "homogenized," this in itself ensures that the butter-fat is easily assimilated even by the most delicate of infants.

Libby's

Evaporated Milk

£1,000 *will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.*

HUMAN TUBERCULOSIS OF BOVINE ORIGIN

At the recent B.M A. Conference held in Manchester reference was made to this important subject, of which the following abstracts (Lancet, Oct. 19, 1929, p 824) are typical:—

"Dr. — —, M O.H., in opening the discussion, estimated the human deaths caused annually by the bovine tubercle bacillus at 2,000 to 2,300. Most of them were the deaths of children, and we had no knowledge as to how many non-fatal infections occurred. As to the extent of bovine tuberculosis among cattle in this country, he thought that about 40 per cent. of the cows were infected; that about 1 per cent. of the cows were 'open' cases; and that about 0·3 per cent. had tuberculosis of the udder."

"Dr. ———, M.O.H., thought that 5 per cent. of the cows had diagnosable tuberculosis. He had found certified milk highly infected with tubercle bacilli. The graded milks were a failure, and pasteurisation was only doubtfully safe. He believed that milk dried by the roller process was the best solution, and he looked forward to the establishment of milk-drying factories throughout the country."

"Cow's Milk made safe and suitable for Baby."

This annual toll of human life, which is mostly confined to young babies, can be eliminated by a suitable heat treatment of the milk. Processes such as pasteurisation have their limitations so far as the feeding of infants is concerned, particularly in view of their disturbing influence on the mineral and vitamin content of milk.

The bacteriological sterilisation of milk is assured by the COW & GATE Improved Roller Process, which also effects maximum preservation of the vitamin content with minimum disturbance of the mineral salts.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

3. FABRITIUS, OSLO

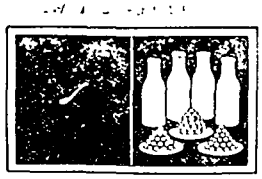
National Committee for Promoting the Consumption of Norwegian Cod Liver Oil, Bergen, Norway.

To combat wasting diseases; to accelerate the process of convalescence; to maintain health: Norwegian cod liver oil is a sure and trusted ally which no doctor can afford to disregard.

Thanks to its prolific content of vitamins A and D, Norwegian cod liver oil is a strong adjuvant in the fight against micro-organisms that cause colds, pneumonia, bronchitis, diarrhoea and rickets. It has been found of the greatest value in restoring to health arrested cases of tuberculosis. It also helps to maintain a healthy skin action.

There is no efficient substitute for cod liver oil.

A TEASPOONFUL OF NORWEGIAN COD LIVER OIL CONTAINS MORE VITAMINS THAN



ALL THE BUTTER AND MILK ANY INDIVIDUAL CAN EAT AND DRINK IN A DAY

Pernicious Anæmia

TRADE MARK 'WELLCOME' BRAND
LIVER EXTRACT

(An Active Selected Fraction of an Extract of Fresh Liver)

Prepared by a process tested and found efficient by the Medical Research Council.

Clinical reports continue to present evidence of the prompt response to the administration of 'WELLCOME' LIVER EXTRACT in pernicious anæmia.

Liver treatment is valuable in cases of secondary anæmia due to hæmorrhage, such as hæmatemesis or post-partum hæmorrhage. Also suggested in conditions due to liver dysfunction and in the vomiting of pregnancy and pre-eclamptic conditions.

In tubes, each containing an active selected fraction of an extract derived from half-a-pound of fresh liver.

DIRECTION. The contents of one tube, or more, daily, in soup or water, or as directed by the physician.

Price in London to the Medical Profession
32/5 *per box of* 12 *tubes*

AN ANCIENT CHINESE FOOTBALL MATCH—PROBABLY THE OLDEST REPRESENTATION OF THE GAME ON RECORD.—The Chinese were exceedingly fond of games in very early times. Although their claim that football was invented in China in the third millennium B.C., cannot be admitted, this game was part of the Chinese military curriculum in the third and fourth centuries B.C. At this period a handbook of twenty-five chapters on football is said to have existed. An interesting passage in a history of the Han dynasty reads: "The Emperor Ch'eng Ti [32–6 B.C.] was fond of football; but his officers represented to him that it was both physically exhausting and also unsuitable to the imperial dignity." His Majesty replied: "We like playing; and what one chooses to do is not exhausting." The football, we are told, consisted of "eight pointed strips of leather made into a ball." It was for long ages stuffed with hair, but from the fifth century A.D. was inflated. The rules of the game in early times can hardly be made out from the illustration, but one of the players seems to be making a high leap to kick the ball with his right foot, striking it also with his stick. In later times goal posts over 30 ft. high were erected and adorned with coloured silks.

Remarks
ON
OCCUPATIONAL DUST.*

BY
JOHN C. BRIDGE, F.R.C.S.Ed., M.R.C.P.Ed.,
H.M. SENIOR MEDICAL INSPECTOR OF FACTORIES.

IT is usual, in dealing with occupations giving rise to dust and their effect on health, to quote mortality figures for these occupations and to compare them with those which may be considered free from dust. Writers and speakers on this subject invariably turn to mortality tables as indicative of the effects on health in various industries. There is no question that such figures are of the utmost value, but it is not my intention to enter into details of mortality rates for various industries; many and more able men have from time to time emphasized the significance of them. As long ago as 1875, commenting on earthenware manufacture in the Decennial Supplement to the Registrar-General's Thirty-Fifth Report, Dr. Farr wrote: "Earthenware manufacture is one of the unhealthiest trades in the country, and the age of joining it is low; but the mortality after the age of 35 approaches double the average; it is excessively high; it exceeds the mortality of publicans. What can be done to save the men dying so fast in the potteries and engaged in one of our most useful manufactures?"

The works on *Diseases of Occupation* by Arlidge and Oliver are full of valuable mortality statistics for various industries. Collis, in his Milroy Lectures in 1915, deals fully—perhaps more fully than anyone else—with the effect of dusty occupations and mortality rates, emphasizing the effects in particular of the dusts of free silica (SiO_2). Dr. W. F. Dearden, in his Milroy Lectures in 1927, struck a somewhat new note, and with indefatigable care examined the sickness certificates of various groups of workers in cotton-spinning and weaving mills. He elicited therefrom the most interesting and significant figures. This line of inquiry seems to me to be one of the greatest possible value, but it must necessarily be, to some extent, dependent on the accuracy of the certificates given by medical men. Dr. Bradford Hill, on behalf of the Medical Research Council, has carried out investigations on similar lines—one for the committee dealing with the question of the health of workers in humid cotton sheds,[1] and another in connexion with the printing industry.[2] No doubt further industries will come under similar review, and I think I am divulging no secret when I say that one is now proceeding on behalf of the Dust in Card Rooms Committee. But if we are to complete the picture as to the effect of dust on health, our inquiry must not stop at either mortality or sickness figures. It is essential, when any particular dust is concerned, to probe further and examine groups of workers exposed to such dust, clinically and with all the necessary accompanying examination—*x*-ray and sputum—and with this we must have a full and complete occupational history of each individual worker in order to study the effects of exposure to dusts of different character. We must go further and confirm our findings, wherever possible, by laboratory experiments.

Dust has been defined as "earth or other solid matter in a minute and fine state of subdivision, so that the particles are small and light enough to be easily raised and carried in cloud by the wind; any substance comminuted or pulverized; powder." Such a definition, in my opinion, would include fume from metal, as it must necessarily be that such fume consists of particles differing only from obvious dust in point of size.

It is fair to state that all manufacturing processes where dry or dried materials are manipulated will give rise to dust, to a greater or lesser extent. It does not, however, follow that there will be danger to health from the dust in every case. In 1864 the Factory and Workshop Act required every factory to be ventilated in such a manner as to render harmless, so far as is practicable, gases, dust, *or other impurities generated in the process of manufacture*, which may be injurious to health. In the Factory Act of 1878 an additional requirement was added, to the effect that in a factory or workshop where grinding, glazing, or polishing on a wheel, or where any process is carried on by which dust is generated and inhaled by the workers, to an injurious extent, an inspector can direct that a fan or other mechanical means be provided within a reasonable time. These provisions are similarly required under the Factory and Workshop Act, 1901. The law has interpreted "to an injurious extent" as including every case in which dust is inhaled to such an extent as *will be injurious in the long run.*" I suppose no more difficult task has been put upon medical men concerned with industry, particularly medical inspectors of factories, than to determine whether any one particular dust is or is not likely to be injurious to health "in the long run."

The problem of occupational dust and its effect on health is one of the utmost importance, and as new methods of diagnosis are available, and made use of, in the examination of workers so exposed, it is my belief that we shall eventually be able to answer with confidence the question asked. The problem of injury to health by this means is not merely whether the dust is in itself toxic, but whether it is present in the air breathed in sufficient amount as to produce toxic symptoms. Sir Thomas Legge was, I believe, the first to lay down a degree of concentration of a toxic dust—that containing lead—which would produce poisoning. Legge considered that

> "somewhere about 2 milligrams, or 0.002 gram of lead, is the lowest daily dose which, inhaled as fume or dust, may in the course of years set up chronic plumbism. Probably if the air breathed contains less than 5 milligrams per 10 cubic metres of air, cases of encephalopathy would never, and cases of colic very rarely, occur."

This standard has been generally accepted.

Recent experimental work done in America in connexion with the toxicity of petrol containing ethyl lead, by exposing men to exhaust gas air mixtures from engines burning ethyl petrol, showed that the maximum amount of lead retained in the body was 27 per cent., and the average was slightly less than 15 per cent., of the lead dust in the inhaled air. Not only, therefore, is the quantity of the dust present in the air an important factor, but also the amount retained after inhalation, and on this question the effect of the electrical charge in the particles of dust may have an important bearing. But our problem does not end here. The size of the particles would also appear to be of much significance in determining the effect of breathing certain dusts. While particles of quartz of 2 μ and under affect the lungs, our knowledge is as yet very incomplete as to the effect of larger particles of other substances in producing pneumonoconioses and other respiratory conditions.

In this paper I can do little but indicate some of the more common forms of injury to health produced by occupational dust. I propose to divide such effects into two arbitrary groups, realizing very fully that some may fall into both groups, and that others included, for want of better knowledge, in one group only, ought properly to be included in both.

Group A: Dusts which exercise a general toxic effect;

Group B: Dusts which exercise a localized effect—(1) internal, (2) external.

GROUP A.

This mainly consists of the dust of certain metals, and chiefly their salts, which produce a definite syndrome. In this group probably the most important syndrome, and one which is still met with most frequently, is due to lead and its compounds. Lead poisoning still figures prominently in the notifications made to the Chief Inspector of Factories under Section 73 of the Factory and Workshop Act, 1901.

* Read in opening a discussion in the Section of Occupational Diseases at the Annual Meeting of the British Medical Association, Manchester, 1929.

I give in the table below the number of cases from various industries over a number of years.

Industry.	1928	1927	1926	1925	1924	1920	1910	1920
1. Smelting of metals	36^2	21^1	26^1	22	28^1	45^3	31^5	24^1
2 Plumbing and soldering	11^1	11^1	7^3	7	6	3^1	25^1	9

4 Printing	3	10	8	8	6^1	9	33^1	18^2
5 Tinning of metals	1^1	3	2	4	3	2	17	5
6 Other contact with molten lead	9^1	17	16^1	17^1	23^1	13^2	17^1	26^1
7 White and red lead works	9^1	21^1	13^1	19^1	20^1	28	41^1	377^6
8 Pottery	23^{10}	11^6	11^{11}	47^5	47^{14}	25^{13}	73^{11}	210^8
9 Vitreous enamelling	2	1	8	9^2	9	2	17	11
10 Electric accumulator works	23^1	58	52	73^1	101	47^2	31	35
11 Paint and colour works	12^1	6	10	8	15	9	17^1	55^1
12 Indiarubber works	1	2	2	2	3	7	3	1
13. Coach and car painting	18^3	14^3	11^2	23^1	30^4	13	79^6	75^5
14 Shipbuilding	7^2	10^1	8	15	8^1	9	21^2	32^2
15 Paint used in other industries	11	7	16^3	14^1	21^2	10^1	51^3	55^5
16 Other industries	10	11^1	11	29^1	22^2	18^1	47	122^7
17 Painting of buildings	87^{20}	93^{21}	93^{18}	85^9	75^9	66^{21}	—	—
Total	329^{43}	317^{35}	332^{46}	411^{22}	551^{41}	289^{44}	595^{38}	1038^{33}

The principal figures relate to cases, the raised figures to deaths.

I will not deal with the question of lead poisoning in detail, but simply consider the important part which lead poisoning plays in industry. There is, however, one point in connexion with lead excretion to which I should like to draw attention. Kehoe and other American observers, in investigating the effect of ethyl lead petrol, found that lead was excreted in measurable quantities in the urine of normal healthy persons who had not been exposed to any known risk of lead absorption. These findings were confirmed on a small scale by Professor Chaston Chapman, a member of the Ethyl Petrol Committee; they are of some importance, for the presence of small quantities of lead in the urine has often been regarded as confirming a diagnosis of lead poisoning in a lead worker.

Arsenic.—The classical symptoms, gastro-intestinal irritation, accompanied by abdominal pain do not often occur in industry due to the inhalation of dust containing arsenical compounds. In the last ten years there have only been three cases so described in the reports received as the result of notification. This is somewhat surprising in view of the large quantities of arsenic oxide used in the manufacture of compounds containing arsenic, especially sheep dip. Some years ago, in the manufacture of Scheele's green (copper arsenite), symptoms of peripheral neuritis were observed. In general, the effect of arsenical dust is manifested by localized affections of the skin, and to these I refer later.

Manganese.—In 1922 Dr Charles of Bristol drew the attention of the department to two cases of manganese poisoning affecting men who were employed in grinding up manganese ore. The symptoms of manganese poisoning may be briefly summarized as follows: languor, sleepiness; mask-like facies; change in the voice, which becomes monotonous and low; retropulsion and, in some, propulsion may occur early, gait later becoming spastic; tremors of the head and limbs, fine in character, with pain and cramp in the muscles, chiefly of the legs; a slight increase in the tendon reflexes. The mental condition is altered, sometimes with hysterical outbursts of crying and laughing. These cases, in the advanced stages, do not recover, though the disease does not appear to progress if the patients are removed from the toxic atmosphere. The disease is not fatal. Cases have been reported in America by Davis and Haey; in the manufacture of manganese steel. I give the symptoms somewhat in detail as, so far as I know, no cases have occurred in this country from a similar occupation or from other occupations where manganese dioxide is used, such as in the manufacture of dry battery cells.

Zinc.—Zinc powder in the cold does not appear to give rise to symptoms characteristic of zinc poisoning—namely, febrile reactions, shivering, headache, followed by cold sweats—but, evolved in the form of fume from molten zinc in brass founding, over the pots in the manufacture of zinc oxide, these symptoms are frequently observed. Some years ago cases of the same character were observed by myself among men employed in breaking up galvanized metal by means of an oxy-acetylene flame. From the experimental work done by Drinker, Thomson, and Finn,[1] similar reactions are produced by breathing fumes of other metals. These authors state that it is probable that the fumes from the burning of iron, nickel, and aluminium in the electric arc would also cause the same general type of febrile reaction, which they term "metal fume fever." It was also found by them that the inhalation of mild doses of magnesium oxide, generated by the burning of magnesium ribbon, produced a leucocytosis and a febrile condition resembling that caused by heavy metals.

Cadmium, which is present in zinc ores, when oxidized has been known to give rise to symptoms due to inhalation. Stevens of Swansea[2] drew attention to this form of poisoning, and found cadmium in the liver of a workman whose case had been diagnosed as lead poisoning. A fatal case was investigated by Legge,[3] in which cadmium was being heated by gas without exhaust ventilation. Two of the workers became seriously ill and an engineer who was supervising the operation died. The symptoms were dryness of the throat, headache, rapid pulse, nausea, and shivering, with brown discoloration of the urine. In the fatal case there was an inflammatory condition of the respiratory and intestinal tracts, fatty degeneration of the heart and liver, haemorrhagia, inflammation of the spleen, and inflammation of the kidneys.

Nitro and Amido Derivatives of Benzene.—The salts of aniline and of the nitro derivatives of benzene and its homologues, from which, in the course of manufacture and handling, dust arises, produce the classical symptoms of anilism—that is to say, cyanosis and dyspnoea. Some of the dust is probably inhaled, but there is also grave risk of this form of poisoning from absorption through the skin. During the past five years aniline poisoning from dust has been mainly reported in connexion with paranitraniline powder, but a number of cases were also found to be due to exposure to dust from dinitrobenzene. Changes in the blood produced by aniline were investigated by Dr. Williamson, in connexion with the work of aniline black dyeing. Dr. Williamson considered that although the number of workers examined was insufficient to justify final conclusions, briefly the order in which the various elements of the blood are affected by aniline was as follows: First, a diminution in the percentage of haemoglobin, which may be altered in its chemical constitution. Following a fall in the percentage of haemoglobin there is a fall in the red corpuscles per cubic millimetre, which, though never very marked, is still quite definite. Lastly, there may be a diminution in the number of white corpuscles, with a relative increase in the number of lymphocytes.[4] During the war much trinitrotoluene in powder form was used in the manufacture of munitions, and, partly by inhalation of the dust, or perhaps more particularly by absorption of the dust through the skin, cases of severe jaundice (toxic jaundice) occurred. Such cases, I am glad to say, are not occurring at the present time, but dinitrobenzol, in a similar way, gives rise to serious symptoms, the chief being cyanosis, gastritis, amblyopia, and occasionally peripheral neuritis. I have also observed in severe cases some degree of icterus. Fatal cases have occurred. As regards chronic cases, anaemia of the aplastic type is the chief feature.

Organic Dusts.—Dusts acting as carriers of toxic substances or organisms, and producing symptoms of a definite general character, must not be forgotten. Fur dust after carotting—that is, painting with nitrate of mercury—has produced mercurial poisoning. Wool-sorters' disease owes its name to the generalized anthrax occurring among wool workers from the inhalation of dust carrying spores of the anthrax bacillus. I am glad to say there

is a remarkable decline in this generalized infection, which is invariably fatal, as shown in the following figures:

Period.	Cases (all fatal).
1909-1913	13
1914-1918	15
1919-1923	10
1924-1928	2

In this group of occupational dust diseases I think we may include those caused by moulds. To take an instance of special interest in Lancashire, there is the condition commonly known as "weavers' cough," where, although the main symptoms are referred to the lung, yet there are general disturbances associated with the lung conditions—namely, headache, thirst, and a feeling of extreme lassitude. Dr. Collis[8] formed the opinion that this form of illness was due to the inhalation of the spores of a mildew. Subsequent outbreaks have shown more or less similar symptoms, and the presence of mildew in warps has been observed. So far, however, it has been impossible to identify any particular form of fungus. In this connexion it is well to observe that to establish a definite relation between a lung disease of this description and the causal agent it is necessary to identify a similar fungus in the sputum or lung juice. Closely allied to such a condition is, I believe, the cough which I investigated a few years ago, affecting men working in malt-houses and exposed to a considerable quantity of dust. Here again, although able to show a fungus of pathogenic variety in the dust, we have up to the present been unable to identify the same fungus in the sputum.[9] No doubt there are other dust-borne diseases due to the presence of a fungus in the dust—for example, in tea dust.[10]

GROUP B (1).

The most important and widespread forms of localized internal disease produced by dusts are the various forms of pneumonoconiosis. It seems to me that the time is not far distant when it would be as well to consider the best nomenclature of the fibrous diseases of the lung produced by dust. The term "silicosis," as denoting fibrosis caused by the inhalation of free silica, is so well established that it would be difficult to alter it, even if it were desirable to do so; but I have recently seen "tobaccosis" as describing an effect on the lung—a term which, to say the least, seems cumbersome.

Of the various forms of pneumonoconiosis, silicosis is at the present time by far the most important. To Collis belongs the credit of drawing attention to the effects of the inhalation of occupational dust containing free silica (SiO_2) in this country, but even Collis did not visualize, I think, the widespread nature of the industries in which dust containing free silica occurs. The recent scheme for compensation under the Various Industries (Silicosis) Scheme gives some indication of this. Previous schemes dealt with silicosis in the Refractories Industries and the Metal Grinding Industries. Silica dust occurs in such widely different industries as the manufacture of pottery, the making of scouring powders containing silica flour, the sandblasting of castings, the making of poultry grit by grinding and crushing of flints, tin and coal mining, and the making of vitreous enamels, as well as in that large industry the sandstone industry, affecting quarriers and masons. The subject of silicosis has, I am glad to say, been dealt with by my colleague Dr. E. L. Middleton, whose unique knowledge of the subject makes any further observations by me unnecessary. (See *Journal*, September 14th, p. 485.)

In 1924 a case of fibrosis of the lung caused by the dust of asbestos was described by Dr. W. E. Cooke,[11] in which he pointed out, in addition to the fibrosis, the presence of certain bodies which have since come to be known as "curious bodies." The first recorded fatal case of fibrosis of the lung in an asbestos worker was that described by Dr. H. Montague Murray in his evidence before the Departmental Committee on Compensation for Industrial Diseases, in 1906. The death occurred in 1900, and Murray stated that in the seven years he had not come across another case. In February of last year Dr. Macgregor, medical officer of health for Glasgow, drew the attention of the Factory Department to an asbestos worker who was receiving treatment in one of the city's hospitals. In March, 1928, the death of an asbestos worker under the care of Dr. Grieve occurred, and at the post-mortem examination the condition of widespread fibrosis of the lung, without tuberculosis, was revealed. A further case, which also terminated fatally, occurred five months later. Recently Professor Stewart[12] of the University of Leeds has shown that the "curious bodies" described by Cooke could be obtained during life by puncture of the lung of an asbestos worker, in the sputum, and after death in the lung juice. It is not suggested, I understand, that the presence of these "curious bodies" indicates fibrosis of the lung, but merely that the occupation of the individual exposes him to asbestos dust.

It may be the subject of speculation why this disease has only recently attracted notice and become a problem in this country. A number of factors have probably contributed to obscure its existence among workers in asbestos, of which the most important seem to be the comparatively small numbers of workers engaged in essentially dusty processes, the insidious nature and general slow progress of the disease, and the difficulty of accurate diagnosis, particularly where tuberculosis is superimposed, as occurred in the first case reported by Dr. Cooke. It may be, too, that the application of exhaust ventilation to the dusty processes in this industry has checked the earlier evidence of the disease by materially reducing the concentration of the dust. Dr. Cooke, in his paper on the subject of fibrosis of the lung produced by asbestos, will, I hope, in addition to other interesting particulars of this condition, throw some further light on the presence of the "curious bodies" which he has described.

In a report of the Director-General of Public Health for New South Wales, for the year ended December 31st, 1927, Dr. Charles Badham, medical officer of industrial hygiene, contributes a section which he calls "Notes on a fine type of fibrous pneumonoconiosis produced by silicates and other minerals." This type of fibrosis, which Dr. Badham desires to call "silicatosis," is found, he says, only after exposure to certain mineral dusts, and can in most cases reasonably be assumed to be caused by various silicates. It is not found in workers who have only been engaged in activities where they are exposed to a high percentage of quartz—that is, 70 to 90 per cent.

Dr. Mavrogordato, in his *Studies in Experimental Silicosis and other Pneumonoconioses* in 1922, found, after subjecting the lung of an animal for eight weeks to dust free from uncombined silica, that most of the dust remained within the cells, and these had not become aggregated, but were scattered more or less uniformly throughout the tissues. Dr. Badham, commenting upon these findings, suggested that the fibrosis found was probably the fine type that he describes.

Collis and Gilchrist,[13] who have studied the effects of the inhalation of coal dust upon trimmers, state that "the clinical observation by *x*-ray examination discloses that, after many years of work, the lungs of coal trimmers are not normal, and exhibit signs similar to those widely regarded as characteristic of silicotic fibrosis." American workers have reported the appearance of pneumonoconiosis among cement workers, and Dr. Badham in his notes mentions a case of a fine type of fibrosis which he has seen in a cement worker in New South Wales.

These few observations show, I think, that we are but at the beginning of our knowledge as to the effect of the inhalation of mineral dusts upon the lungs of workers exposed to such dusts. It may well be that in time, with a more complete survey of workers exposed to particular dusts, it will be possible to determine, by clinical and radiological examination, the particular form of dust by the character of the fibrosis to which it gives rise. I hope that the inquiry which is now being carried on by my colleague Dr. Merewether of the Factory Department, into the effect of asbestos dust, will materially assist in this direction.

Vegetable Dusts.

Of the effects of vegetable dusts on the lungs little or nothing is known. In 1924 Dr. Middleton with Mr. McNair, H.M. Engineering Inspector of Factories,[14] made some investigations into the dust to which workers were

exposed in the processes of discharging and handling of grain cargoes. Dr. Middleton collected samples by means of Owens's dust-counter, and examined these samples. He found that the dust in the atmosphere consisted of two kinds: (1) sharp spike-like hairs, and (2) fragments of vegetable and mineral matter, spores, etc. Dr. Middleton formed the conclusion that the dust in the case of wheat, barley, rye, and oats contains hairs derived from the grain which on *a priori* grounds appear to be capable of causing irritation of, and inflammatory changes in, the respiratory passages. No other constituent was discovered in the dust met with during this investigation which would be capable of producing the symptoms experienced by the investigators or of causing serious injury to health.

Dr. Middleton investigated a case of loss of sight in a woman employed for twenty-five years at a bench where she had been exposed to inhalation of pure tobacco dust, most of it caused in the intermittent process of sieving. The case—the first recorded in this country—was diagnosed by the ophthalmic surgeon of a general hospital, and other possible causation, as far as possible, excluded.

One cannot leave the effects of occupational dust on the respiratory organs without reference to the increase in cases of cancer of the lung, to which Dr. Dugund drew attention in an article published in the *Lancet* of July 16th, 1927. His observations are intriguing and suggestive, particularly when read in conjunction with the work of Rostoski and Schwarl on lung cancer. Nor must we forget that it was from a survey of cases from the Manchester Royal Infirmary, by the late Dr. Wilson and by Dr. Southam, that the now well-recognized cancer of the scrotum among mule-spinners was first brought to light.

The part played by inhaled dust in the etiology of cancer of the bladder cannot be ignored. The following table gives particulars of cases occurring in workers in the manufacture of synthetic dyes in chemical works since 1924, which have come to the notice of the Factory Department.

Initials	Age at recognition.	Occupation	Result.
R. J.	41	Collier 19 years, army 4 years, colour driver in chemical works 6 years	Died Sept. 17, 1925
J. W.	54	Brass emoker 22 years, in soap department of bone factory 11 years, army 1 year, fitting casks with size 2 years, burning sulphur at mine 2 years, in chemical works 6½ years	Died in 1927.
A. S.	38	Brush stock wood turner 16 years, in chemical works 10 years	Died June 30, 1925
A. B.	48	Worsted spinner 12 years, wool comber 11 years, in chemical works 18 years	Died July 20, 1921.
W. B.	65	In chemical works 20 years	Died Nov. 11, 1925.
A. S.	51	Aniline black dyer 20 years, in chemical works 29 years	Alive.
W. A. S.	60	Machine printer 20 years, in chemical works 20 years, picric storekeeper 7 years	Died Sept. 29, 1925.
T. G. G.	63	Purifier of anthracene 6 years, in chemical work 33 years	Died Dec. 9, 1924.
J. T. F.	70	In chemical works 52 years, watchman years	Died Dec. 16, 925
R. H.	56	In chemical works 33 years	Died Dec. 19, 1924.
W. T.	52	In chemical works 38 years	Died Aug. 19, 1927.
J. N.	63	In chemical works 48 years	Died Aug. 13, 927
W. H.	61	In chemical works 21 years	Died Apr. 22, 19 7

A few fatal cases of cancer of the bladder have also been noted among pitch workers. Their occurrence may be of importance.

GROUP B (2).

The localized diseases produced by occupational dust are those affecting the skin and mucous membranes. Many may not agree that the skin lesions are localized, but often general, affecting in some cases the whole surface of the body, yet I believe it correct to say that the starting point is a particular area, and for this reason I include them in this group. It is an interesting fact, and I say it with due deference, that the general extension of a localized skin lesion produced by dust has not been fully explained.

There are few, if any, dusts occurring in industry that will not produce, in certain individuals, an inflammatory condition of the skin, and this not only makes difficult the decision as to whether or not a dermatitis is of occupational origin, but also the actual causal agent in many cases a matter of some doubt. The importance of the dermatoses produced by dust, and the loss to industry by such conditions, is apparent by the number of cases for which compensation was paid for dermatitis produced by dust or liquids in the last five years—namely, 390 in 1923; 564 in 1924; 691 in 1925; 837 in 1926; and 1,629 in 1927. The marked increase in the number of cases ascribed to industry is difficult to attribute solely to altered industrial conditions.

It would be impossible to refer to even a small number of the dusts which produce skin reaction, nor would it be profitable. I feel I am treading on holy ground when I so much as mention occupational diseases of the skin in Manchester: the work of Prosser White in connexion with these is so well known, not only in Manchester and Lancashire, but wherever these diseases engage the attention of those interested in industrial medicine. From my own experience the dusts which appear to exert the most rapid and severe conditions are the nitro compounds of benzene and its homologues—for example, dinitrochlorbenzene, trinitrophenol (picric acid), paranitraniline. Of simple compounds, the sodium and potassium salts of chromium and the caustic alkalis produce not only skin lesions, but ulceration of the mucous membranes and septum of the nose, leading to complete perforation. The absence of untoward symptoms following such definite destruction of the internal nares, as is so often seen, is a matter of surprise to me. I have never seen any serious disturbance in the normal functions following this loss, nor, so far as I know, has any case of such a nature been recorded. One might have supposed, at any rate, that the septic infection necessarily occurring during the process of ulceration would, in some instances, extend beyond the cartilage and bones of the internal nares.

Sometimes it is not the dust itself which produces the skin lesions. I well remember an outbreak of rash affecting men unloading a cargo of barley from a ship, which I investigated. Not only were the workers affected, but the crew of the vessel, including the master, also suffered. Intense itching was the chief cause of complaint, and there was no difficulty in demonstrating the cause to be due to the presence of a mite, the *Pediculoides ventricosus*. Although the cause was easy to find, the cure and prevention were different matters.

However distressing and economically wasteful simple lesions of the skin produced by practically all dusts may be, they are as nothing compared with cancer of the skin produced by dust. Epithelioma produced by pitch and arsenic dust must be of special interest in Lancashire, owing to its similarity to the cancer affecting mule-spinners. Even though the main incidence occurs among the patent fuel workers in South Wales, the pitch workers in gas works, the loaders and unloaders of pitch, and the workers exposed to pitch dust in tar distilleries, wherever they may be, share the risk. The number of cases reported since the disease became notifiable in 1920 is as follows, and for interest the number of cases among mule-spinners is also given.

Industry.	1920	1921	1922	1923	1924	1925	1926	1927	1928
Pitch workers ...	32	24^2	23^1	25^2	23^1	35^9	49	31^1	32
Mule-spinners .	—	—	—	15^1	79^{17}	78^{35}	88^0	121^{31}	101^{26}

The principal figures relate to cases; the raised figures to deaths.

The higher incidence of mortality from cancer of the skin among coal trimmers exposed to coal dust has been pointed out by Collis and Gilchrist. What relationship there is between the disease and this occupation is as yet speculative, but it is significant.

Though the number of cases of skin cancer among workers in arsenic is few, yet the connexion between their exposure to the dust and the disease is, I think, well established, and confirmed by the animal experiments of

Leitch and Kennaway.[15] The occupation chiefly affected is that of the manufacture of arsenical sheep dip.

Of the oldest form of cancer of the skin—namely, that of chimney-sweeps, the number of cases recorded is small, though still occurring. In 1927 two received compensation. The spread of soot on the land has possibly been responsible for cases among agricultural workers. One case which I believe may have been thus caused came to my notice last year.

This brief review will, I hope, give some idea of the extent of the problem of occupational dusts: but the problem does not end when it has been established with certainty that any particular form of dust is a cause of a pathological condition. While once the masters of cure, we are now, or ought to be, the slaves of prevention.

Prevention does not, in the case of disease produced by occupational dusts, rest with the medical profession, although we may be able to assist. The sure and only certain way of preventing dust affecting the worker is to prevent its formation, or, if this is impossible, to secure its removal before reaching the workers. It therefore seems to me that just as there is need for research on the medical side in regard to the effects of dust, the methods by which dust can be eliminated, either by a modification of the process or alternatively by effective removal, call no less for research. Chemists and engineers take so very great a share in the prevention of disease that I look with hopeful anticipation to their efforts. Our own task may be the easier, but though their difficulties be great, they are, I believe, not too great for our colleagues in the other sciences to overcome. A dust-free industry may be ideal, but it should be our goal.

SOME POINTS IN CONNEXION WITH CATARACT EXTRACTION.

BY

R. H. ELLIOT, M.D., F.R.C.S.,

LIEUT.-COLONEL I.M.S. (RET.).

THE advice given to cataract patients in Europe varies so greatly with different surgeons, and is so often opposed to my own practice, which has been founded on many thousands of operations for cataract, that in compliance with requests from various sources that I should restate my views, I desire to do so shortly.

The Stage at Which the Operation Should be Undertaken.

The usual advice given is that a patient must wait until the cataract is mature before undergoing operation, even if the sight in the opposite eye is so defective as to make him or her nearly helpless, or at least partly dependent on others. The first point I would insist on is that the exact date for operation should be decided after a careful consideration of all the factors in each individual case. One cannot lay down a general hard-and-fast rule for the guidance of students. The patient's age, the state of his health, his prospects of life, the condition of the second eye, and a number of other factors must be carefully weighed before giving any definite advice. A few points may be considered with profit.

A patient is frequently told that if the second eye sees well, it is a mistake to have the first one touched. Such advice seems to me eminently unsound in a number of cases.

1. To be blind on one side exposes a man to injury. He runs into people, lamp-posts, etc.; moving objects run into him because he has not sufficient warning of their approach to avoid them. Serious accidents happen in this way, especially from bicycles and trade tricycles ridden by careless young people. It is admitted that one cannot fit up an aphakic eye with a lens and enable it to work accurately together with an unoperated and useful eye on the other side, but this does not mean that an aphakic eye cannot be made a very useful organ. On the contrary, it can, even when uncorrected by glasses, be made to add a large element of safety and security to the patient's life as well as to his comfort and happiness—no unimportant matter.

2. Cataract operations are practically always performed on elderly people, and elderly people go downhill, so far as health and resistance are concerned, at a rate quite disproportionate to that met with in the young or even in the middle-aged. Apart altogether from disease, every year lessens a patient's resistance to operation. He is a better subject at 70 than at 71. This is even more the case between 80 and 81, and so on. A case that will do well one year may easily end in failure a year or two later. The incidence of an attack of influenza, of bronchitis or bronchial pneumonia, of a stroke, or of many another illness, may just make the difference between a patient being a good subject for an operation or a very bad one. The opportunity of successful operation may thus be lost, never to return, with the result that the man is condemned to permanent blindness. All the interest is thus taken out of his life, and he too often sinks to the level of a human cabbage, a burden to himself and to all about him. This does not mean to say that any patient is too old for a cataract operation, provided there are sufficient indications for performing it, but it is a strong argument against putting off operation. Much more depends on the patient's actual state of health than on the number of years he has lived. One man is old and worn out at 55, another is playing games and hunting at 60, or is still robust and leading an active life at 70 or even at 80. I have three times operated at 90 or over. All three patients did well, including an old lady of 96.

3. No patient should be allowed to go blind and to drop his normal activities. With modern methods of operating, any lens can be safely removed, however immature the cataract that darkens its vision. More care is required and the convalescence may be lengthened owing to the need to allow left-behind cortex to be absorbed, but, always provided the operation is skilfully and aseptically carried out, the added risks are, in my experience, so slight as to be almost negligible, and certainly not worth weighing against the serious disadvantages of allowing an elderly person to drop the activities of a lifetime with the risk that he will never take them up again. It is much easier for the old to drop their habits than to take them up again, and few things are more tragic for the relatives than to look on helplessly at the decay of everything which once endeared the patient to them, or brightened the life of one they loved. When a patient reaches the stage in which he can no longer get about comfortably, or in which he cannot read, write, and carry on his usual occupations with moderate comfort, or cannot do either of these things, he should be operated on without delay.

4. The hypermaturity of a cataract may bring in its train definite risks to the eye. These are less appreciated in Europe than they are in India, for in the great majority of cases over here a cataract is removed as soon as it is mature, or very soon after, whereas in India, owing to the ignorance of the people, to the difficulties of obtaining skilled relief, and to other causes, a very large number of patients are allowed to retain their mature cataracts for years, and often indeed up to death. The opportunities for observing the dangers consequent on hypermaturity are therefore much greater in India than in

the West. The two principal sources of risk are secondary glaucoma and a slow form of iritis. In Madras practice we estimated that about 3 per cent. of hypermature cataracts, if left to themselves, develop secondary glaucoma. When account is taken of the small number of cataracts that are allowed to reach hypermaturity in Europe, this may not sound a big risk, but it is an appreciable one, and, together with the form of iritis I have spoken of, it constitutes, to my mind, a distinct argument in favour of operating as soon as a cataract is mature. It remains to add that the type of cataract in which secondary glaucoma is most to be feared is the one in which swelling takes place as the result of inhibition of fluid. Such cataracts have a white, shiny appearance, and often present mother-of-pearl sectors; moreover, they are associated with a shallow anterior chamber owing to the bulging forward of the swollen lens. Other types of cataract in which the lens is large may be complicated by the onset of glaucoma, and a brown lens is not necessarily above suspicion, especially if it appears to bulge forward into the anterior chamber and if it is associated with a shallow chamber. It is obvious that such considerations as the above must be carefully weighed by the surgeon when making up his mind as to the date on which he advises that an extraction should be performed.

5. With regard to the factor of morale in cataract extraction, it is most important that a patient should enter on the ordeal of an extraction with his hopes and courage high; far more depends on this than many surgeons realize. In any case the patient must spend long hours with his eyes bandaged, wondering what the future holds for him, never ceasing to think, while ever trying to pierce the mists of the future. If both eyes are blind, or nearly so, his fears are intensified, for all his future depends on the result of the operation. Before his mind there hovers unceasingly the nightmare possibility that in the event of failure he will never see again. In all our tongue are there any words more dreadful than "never again"? If, on the other hand, he still has some sight in the better eye, he knows that he will at least have the sight he had in the better eye before the operation; this lends him courage and calmness in his hour of trial. As he broods over the possibility of a failure in the surgeon's efforts, his anxiety is at least tempered by the comforting reflection that in any case he still has the better eye to fall back on. I look on this as a factor of great importance, and my own personal choice is always to operate if possible while the second eye is still useful. This leads me on naturally to

The Question of Operating on the Second Eye.

When a patient has a good result in one eye, is it advisable for him to have the other eye operated on or not? I have no hesitation in replying that, unless there is some strong contraindication, the extraction of the second cataract should be proceeded with at an early date. I will give my reasons for this opinion.

1. The question of "morale" just discussed comes in strongly here again, for, however good the result of an extraction may be, it is obvious that the sight of the operated eye may subsequently be lost in a variety of ways. Injury, retinal haemorrhage, glaucoma, and a host of other evils lie in wait for the old patient—and the cataract patient is almost invariably old. One cannot afford to take any risks where sight is concerned—it is too valuable; and therefore I urge every cataract patient to make his margin of safety as wide as possible and to have the second eye operated on at an early date, whilst the sight of the first is still good.

2. Two eyes see better than one, just as two ears hear better than one, or the two sides of the nose smell more acutely than one. Having the second eye operated on usually materially improves the sight for near and far distances; it gives stereoscopic vision, and it greatly widens the visual field. A blind eye on one side is, as previously pointed out, a distinct danger to the patient.

3. There is the question of the coloration of vision after extraction. Many years ago, when I pointed out how frequent blue vision was in Indian practice after extraction, I was told it was a phenomenon rarely if ever observed in Europe; but fifteen years of practice in London has proved to me that it is far from a rare complication here. To some patients it is very annoying. It often persists in some degree as long as the second cataract is left, but it disappears as soon as the second cataract is extracted. This is another argument for the operation on the second eye.

4. There is a last point, already discussed in another connexion—namely, that the patient's resistance fails with each advancing year, and therefore the earlier the operation is done the better.

Once again I would repeat that every case must be given individual consideration, all the pertinent factors being taken into account; for example, it would obviously be foolish and wrong to operate on an old patient who had only a very short time to live, and who had been severely tried by the first extraction. The successful practice of medicine is largely a question of common sense. We must leave it at that.

Precautions and Method of Operating.

It is to be remembered that the safe removal of a cataractous lens is not the affair of waving a wand, like some act of magic; it is rather to be compared to the slow sapping of a military position. An eye, unlike some other parts, gives the surgeon no second chance. He must therefore adopt the safest possible routine. The best ophthalmic surgeon is, like the best general, the man who makes fewest mistakes, especially in the initial stage. To put this in another way, he is the man who takes fewest risks. He must therefore deserve success by the meticulous care of his technique. The teeth must be seen to, and all other sources of auto-intoxication must be excluded; the conjunctiva must be rendered healthy and sterile by careful preparation; then a preliminary iridectomy must be undertaken; a month later the cataract can be extracted; this should be done under a conjunctival bridge. It is true that the presence of such a bridge adds considerably to the difficulty of delivering the lens, but in skilful hands it makes the operation much safer and is a great factor in ensuring a smooth after-course to the case. Colonel Kirkpatrick and I, in common probably with many other surgeons, have been operating under a conjunctival bridge for many years now, and neither of us would think of ever reverting to the old operation incision. With a good bridge, leaking sections have become a thing of the past; even in the aged the section is found soundly healed twenty-four hours after the operation.

Six weeks after the extraction any after-cataract can be dealt with by discission. Even then, a wait of some weeks is necessary before lenses are prescribed for near and distant vision. During all this time it is most important that the patient should have useful vision in the other eye; he should have at least enough to enable him to get about unaided, and if he has enough to read, write, etc., so much the better. This has all to be borne in mind when fixing the best date for operation. I make a point of allowing a patient to use his unoperated eye as soon as possible, and have never had reason to regret doing so. My rule—a common-sense one, I think—is, "Let him do anything that he can do without pain or discomfort, either in the operated eye or in its fellow." What he finds he cannot do to-day he will be able to do in a few days' time. This cuts his limitations down to a minimum and greatly adds to his happiness and comfort, as well as to the peace of mind of the relatives, who are only too apt to hunt him with needless restrictions. He must be a law unto himself, with this proviso—that he must always err on the side of doing too little rather than too much.

Considerations Arising from the Presence of General Disease.

It appears to be the custom of many able surgeons in England to refuse extraction to patients suffering from diabetes or glycosuria, or at least to lay great stress on the risks of operating in such cases. In India quite a large number of cataract cases are found to have sugar in the urine, and experience there shows how good the results usually are after an extraction, when carefully undertaken. I have, in consequence, operated on a number of such cases in England, and with very happy results.

"Provided the patient is in a good state of general health and is not losing weight, the presence of sugar in the urine is not, to my mind, a contraindication to the performance of an operation, so long as diacetic acid and acetone are absent. The wound heals well, and convalescence does not appear to be interfered with. It is an obvious indication to make a careful examination beforehand and to attend to the diet and to the general regimen on such lines as will ensure the patient being in as favourable condition as possible for the ordeal before him."

The above is an extract from my book on *Tropical Ophthalmology*, published in 1920 (p. 502). I would not go back on a word of it. It has always appeared to me that to deny a hope of sight to a patient on the ground that he has sugar in the urine is unnecessary, and often cruel. The same remarks apply to patients suffering from wasting and nervous diseases.

Much stress has been laid on the difficulties of operating on a patient with pathological tremor. Even the presence of a very marked and persistent tremor adds comparatively little to the difficulties, either of the iridectomy or of the extraction, when undertaken by a skilful surgeon, though doubtless it might considerably embarrass a beginner.

The leprotic eye is rare in this country, but I should like to record my conviction, founded on clinical experience, that major operations on the eye, such as iridectomy, extraction, and trephining, do well even in advanced cases of leprosy. The wounds heal with remarkable rapidity, owing, presumably, to the vascularized state of the tissues, and material advantage is often gained, even in cases that appear to offer but little hope. The general condition of the leper must always be attended to first.

Announcement of the Diagnosis of Cataract to a Patient.

I have many times seen a patient who has been shocked, frightened, or made very indignant by the blunt announcement to him or her of the diagnosis of cataract. Sydney Stephenson used to say that the greatest factor in the success of a medical man, and especially of an ophthalmic surgeon, was "human sympathy." I have always agreed most cordially with this dictum. Apart, however, from the sheer folly of handling a man or woman faced with so serious a condition as cataract in the way I have alluded to, there is another point of great importance. The term "cataract," flung in a reckless way at a patient, often conveys a totally erroneous impression to his mind. We as surgeons distinguish between a large number of quite different conditions, all of which we class as cataracts. Some of them are more or less rapidly progressive, and lead to blindness which can only be relieved by operation; others are partial and of very slow progress; indeed, such cataracts often change so slowly that the patient dies many years later with useful sight to the last. To call these "cataracts" is technically correct, but practically very unsound, for it has two results: (1) it frightens the patient and gives him and his relatives years of needless misery whilst a sword of Damocles hangs suspended above their heads; and (2) it drives him to quacks, who charge him large sums of money for dropping harmless solutions in his eye, and who point triumphantly over a series of years to the wonderful effects of their remedies in "delaying" the progress of the disease, "which a surgeon of repute diagnosed and said could only be treated by operation." Medicine is largely a matter of common sense and of the application of common-sense principles by a sane and sympathetic mind. If, in the end, we have to tell a patient that he really has a cataract, of the variety that he understands by the term—the kind of thing his uncle or his father had and was operated on for—it is essential that we should place ourselves in his position and break the news to him as gently and as sympathetically as it can be done. This advice is not at all "the flogging of a dead horse"; many times every year I meet with people who have been "shocked" by the manner in which the diagnosis of cataract has been conveyed to them.

Promises of Results from Operation.

From time to time one meets with a patient who is bitterly disappointed because, according to his statement, a surgeon has promised him a good result and failed to get one. It seems very unlikely that any surgeon would *promise* a good result, but it is most important that in every case the patient should be made to understand clearly that, in such operations as those for cataract, promises are impossible, and that the most a surgeon can do is to state the probabilities. Any other course is dangerous to the surgeon's reputation.

Limitations of a Patient's Activities during the Development of a Cataract.

Whilst a cataract is progressive, ought we to limit the patient's activities. I see a number of people who have been told not to read or write or "strain" their eyes. The idea is to avoid causing the cataract to advance. To my mind, these rules are founded on no solid basis. My rule for cataract patients is, "Go right ahead, live a normal life, forget all these directions, and make your own experience your guiding rule. It is probable, or at least possible, that anything which makes your eyes tired or causes them to ache or gives you headache is bad for you; therefore avoid all such things or cut them down to the point where they do not produce symptoms, but do not go farther in this direction." I believe that if a cataract is going to advance nothing the patient can do will retard it; on the other hand, if it is not advancing or is doing so slowly, I doubt if the ordinary use of the eyes will prejudicially affect the course of the case. I have very frequently released patients from these troublous restrictions which have been put upon them, and I have never found they were any the worse for this freedom. The advance of a cataract appears to be a trophic change, comparable to the wrinkling of the skin or the loss of hair, and the only treatment I have ever found to be of the slightest use has been the exhibition of thyroid gland in suitable cases. This has several times seemed to have been of great value. I do not put the case any stronger than that.

Restraint and Invalidism after Operation.

In the three weeks or longer, after leaving the nursing home between a preliminary iridectomy and an extraction, a patient can usually carry on his ordinary work, always provided that it does not cause pain to either eye, but after extraction it is most inadvisable for him to attempt to do this for at least a month, and even then he must carefully feel his way. When, however, it is a case of using his brain and not his eye, there is no reason in the world to prevent him directing his business as soon as he leaves the home, or even earlier when it can be done by reports read to him and instructions taken down by a stenographer.

A most important thing after operation is to protect the eye from chills, and especially from those due to wind. I insist, for some time afterwards, on the steady use of goggles when the patient is in the open air unless the day is windless and warm. In the house he can wear a shade or his ordinary glasses or his goggles or nothing, according to which seems more comfortable to him.

HUNTINGTON'S CHOREA.

WITH REPORT OF TWO CASES.

BY

C. WORSTER-DROUGHT, M.A., M.D.CAMB., M.R.C.P.LOND.,

PHYSICIAN TO THE WEST END HOSPITAL FOR NERVOUS DISEASES AND TO THE METROPOLITAN HOSPITAL;

AND

I. M. ALLEN, M.D.N.Z., M.R.C.P.LOND.,

SENIOR RESIDENT MEDICAL OFFICER, WEST END HOSPITAL FOR NERVOUS DISEASES.

HUNTINGTON'S chorea is defined as a hereditary disease characterized by irregular movements, disturbance of speech, and progressive mental deterioration. First described by Lyon in 1862 as chronic hereditary chorea, it was further investigated by Huntington and later by Davenport, who found nearly one thousand cases in four great family groups. The salient features of the disease, as determined by Huntington, are heredity, the late onset, and the mental changes.

The cases reported presented certain interesting contrasts which render them worthy of discussion. In the first case the disease ran the usual course of choreiform movements

beginning in early middle life and continuing for some years, followed by the gradual development of dementia. In the second case this order was reversed—an occurrence noted by Davenport during his investigation of the disease, but certainly very uncommon in the history of the condition. Dementia preceded the onset of choreiform movements by nearly four years. The history of the family for three generations has also been investigated, and five further cases of the disease were found. Among them was one case in which choreiform movements were present without the development of dementia. In addition, the manner in which the disease is inherited is considered as far as possible from the material available.

Personal Cases.

CASE I.

This patient, a woman, was first seen in September, 1923, when she was 40 years of age. She then complained of being nervous, of constant twitching movements, and of difficulty in walking. These symptoms had appeared four or five years previously, when she was between 35 and 35 years of age. She became apprehensive in the presence of strangers, was easily startled, and tired on slight exertion. Sleep was good. All other functions were normal. Three years before she had had an operation for removal of the appendix, and had apparently become much worse since then. The family history is dealt with in another section of this paper.

Condition on Examination.—The cranial nerves were all normal. Sensation was normal. Motor power, muscle tone, and the deep reflexes were all normal. The plantar reflexes were flexor. The other organs were healthy. The patient looked ill. She was constantly grimacing, her speech was explosive, and she exhibited movements characteristic of Huntington's chorea. The gait was stiff and awkward, somewhat like that of hemiplegia. At that stage the choreiform movements, the grimaces, the explosive speech, and the gait were all regarded as characteristic of Huntington's chorea, an opinion which was supported by the fact that it was known that the patient's father and paternal grandmother had also suffered from the same condition.

The patient was placed in a nursing home, and there she appeared to be quite happy with her surroundings. Two months later it was reported that she appeared to be unduly exciting herself about her business affairs, and was apparently making herself worse. Her condition was such that it was considered advisable to obtain her admission to a mental hospital as a voluntary boarder.

By March, 1928, the patient was becoming rather excitable from time to time, possibly as a result of the change in her surroundings.

Further Examination (June, 1929).—The choreic manifestations were not materially worse, but there was evidence of some degree of mental deterioration. Generally, she was rational in her behaviour and answered questions correctly, but was inclined to reiterate the answer or an observation several times. For example, she repeated a number of times the sentences: "My only brother looks after all my money affairs," and "Will the chorea die out as I am not married?" Apart from the chorea, her behaviour was rational. Her scholastic attainments were fairly good. She was able to read, but writing was very difficult and slow on account of her motor disability. When trying to write her hand was quite steady, but the head, face, and tongue continued all the choreic movements.

Her social capabilities were normal. Ideation was fair, but some degree of dementia was present. Her intelligence was limited. Perception was also limited. It was necessary to repeat a question several times before it was perceived. Emotionally, she was good tempered, was not depressed, but rather cheerful. Her attention was difficult to hold, and she was inclined to wander off into repetitions of what she had said. Recent memory was poor, but that for remote events was rather good. Orientation in regard to time and space was normal. Her reasoning power and ethical attitude were fair. There were neither hallucinations nor delusions. Sleep was good, nutrition was good.

When walking she constantly assumed attitudes, the hands and arms being thrown out alternately in a gesticulatory fashion, the feet being put down sharply and grotesquely, the wrist rotating and the fingers constantly flexing and extending. The head was carried somewhat forward. The patient continually grimaced, especially with the frontalis muscle, which was in a constant state of elevating the eyebrows. The movements were quieter when the patient was lying in bed.

There was a slight increase in tone in the upper part of the arms, the shoulder girdles, the thighs, and the pelvic girdles. The pupils were moderate in size and reacted normally. The optic discs were normal. There was no nystagmus. The ocular movements were normal. It was impossible to protrude the tongue, probably on account of its frequent choreic movements. The palate moved normally. There were constant facial grimaces. The other cranial nerves were normal. The tendon-jerks in the arms were present and equal. The knee- and ankle-jerks were sluggish and equal, and the plantar reflexes flexor. There was no Rombergism. Co-ordinated movements were performed satisfactorily. No other abnormalities were detected on physical examination.

CASE II.

The elder sister of the above patient came under notice in June, 1924, when she was 45 years of age. She herself complained of nothing except nervousness and a fear of traffic.

History of Present Illness.—Inequality of her pupils had been noticed when examining her sister, whom she accompanied at the time. For three months she had been strange in her manner and had done foolish things, such as selling a house at much below its value. She had become loquacious and unusually silly.

Family History.—She lived apart from her husband. The rest of the family history is dealt with under a separate heading.

Condition on Examination.—The right pupil was slightly larger than the left. Both reacted sluggishly to light and consensual stimulation, but briskly to accommodation. The optic discs were normal. Her speech was "wide" and slightly slurred, but she was able to say "British constitution" correctly. There was no tremor of the tongue or of the lips. The other cranial nerves were normal. Sensation was normal. The upper limbs were normal, and the tendon-jerks present and equal. The lower limbs were normal; the knee-jerks present and equal; the ankle-jerks present and equal; and the plantar reflexes flexor. The abdominal reflexes were very sluggish. There was no tremor of the hands. Co-ordination was fair. The other systems were normal.

The patient was excitable, loquacious, and irritable. She asked childish questions, and was obviously unfit to manage her private affairs. She was dishevelled and slovenly in her appearance, and not fully dressed even in the afternoon, contrary to the custom of her social status. She laughed uproariously, inanely, and frequently at trifles and without due cause. She stated that she was bankrupt, which was not the case. Her conversation was frequently irrelevant and incoherent. She was dirty in her habits. She stated that her brother was an inveterate gambler, which was untrue. Facts observed by others showed that she was frequently abusive, used foul language even in front of her children, and had attempted violence to those about her, so that they were compelled to run away from her.

Cerebro-spinal Fluid.—There was no excess of cells; the Noguchi test resulted in very slight flocculence, the Lange colloidal gold test showed no changes; and the Wassermann reaction was completely negative. The blood Wassermann reaction was also negative. Because of her mental condition the patient was then certified as of unsound mind.

In March, 1925, her mental condition was no better. She had improved as regards her personal appearance and physical condition, probably as a result of the care bestowed upon her. She had more control over her speech and emotions. The mental deterioration was, however, still present.

In October, 1925, the patient was more demented. She was dirty in her habits and slovenly in her appearance. Her speech was slurred. She was very emotional. Maniacal attacks occurred at intervals. On examination slight proptosis of both eyeballs was observed. There was a slight von Graefe sign. The pupils were normal. Slight tremor of the hands was present. The reflexes were all brisk. The knee- and ankle-jerks were present and equal. The plantar reflexes were flexor. No other abnormality was detected. On the whole the mental condition of the patient had deteriorated.

Further Examination (June, 1929).—The patient was re-examined on this date with the following results.

Cranial Nerves.—The pupils were equal and reacted normally. The ocular movements were normal. There was no nystagmus. The face was rather fixed in repose. The other cranial nerves were normal. It was impossible to test the sensation satisfactorily on account of the patient's mental condition.

Upper Limbs.—Motor power was diminished in both arms. Muscle tone in the right arm was slightly increased in the proximal groups of muscles. In the left arm tone was much increased in all groups of muscles, more particularly proximally. The left arm was held flexed across the chest both at rest and when walking, together with partial flexion of the wrist and fingers. The right arm assumed the same position but to a lesser degree. It was impossible to elicit the tendon reflexes on account of the increase in muscle tone.

Lower Limbs.—Motor power was decreased in both legs. Muscle tone in the left leg was increased in all groups of muscles, but more particularly in the proximal groups. In the right leg tone was slightly increased in the proximal groups of muscles. The left leg was extended. There was no wasting. The knee- and ankle-jerks were present and equal. The plantar reflexes were indefinite.

Gait.—The whole body moved *en masse*, with the left arm held flexed across the front of the chest. The right arm was slightly flexed, while the right leg was in an extended position. The left leg was extended and moved stiffly. The arms did not swing.

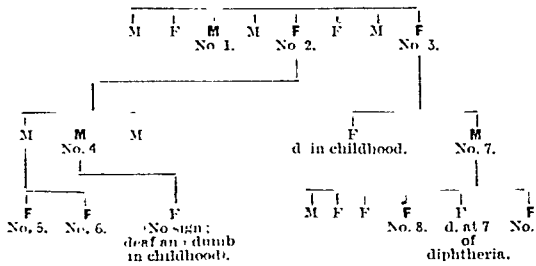
Spontaneous Movements.—There were no movements when the patient was alone or at rest. On attempting to speak or to perform any action typical choreic movements appeared. There was constant grimacing; the tongue was protruded at the right angle of the mouth; the arms were twisted and turned, but their movements were much less pronounced than those in the face. There was occasional and slight twisting of the body.

Co-ordination.—In carrying out the finger-nose test with the right hand, the choreic movements appeared at once, but the patient succeeded in reaching the object although by a roundabout route. With the left hand the choreic movements began at once and the patient desisted.

Mental Condition.—She talked constantly in a loud voice, was quarrelsome, and hit the attendants without warning. Her recent memory was poor, but she remembered how long she had been in the hospital. There was perseveration in both speech and action. Once a line of speech or action was begun, it was repeated several times, during which it was impossible to introduce anything else to her attention.

The Family History.

The subjoined table illustrates the occurrence of a similar condition in several members of the family, the dark letters indicating the members affected or suspected to be affected. In most cases some details of the clinical history were available, so that it has been possible to identify the condition in each case.



Records of three generations of the family are available. In the first generation, the disease appeared in three members of one family—namely, No. 1, the third child, a male; No 2, the fifth child, a female, who married and had a family; and No. 3, the eighth child, a female who also married and had a family. The daughter (No. 2) had three sons, the second of whom suffered from the disease (No. 4). Her elder son had two daughters, each of whom developed choreiform movements between the ages of 10 and 12. These are discussed as No. 5 and No. 6. The third member of the original family affected (No. 3) had a daughter and a son, the former being killed in early childhood and the latter becoming affected in middle life (No. 7). He was the father of the two patients described in this paper (Nos. 8 and 9). These patients were respectively four and sixth in the family, the three eldest children having escaped and the fifth having died of diphtheria at the age of 7. The information available about the affected members of the family is as follows.

No. 1.—Male, the third child of the original family. The condition appeared at the age of 50 years, and the patient died unmarried at the age of 81.

No. 2.—Female, the fifth member of the original family. No information is available except that she developed the disease shortly after the age of 40 years, and died at the age of 86.

No. 3.—Female, the eighth member of the original family. She was born in 1806 and appeared to be a very bad case of the disease. From information given by friends who remember her, it is believed that she developed the disease *about the age of* 50 years, and died at the age of 81.

No. 4.—Male, the second son of the patient (No. 2) described above. The disease appeared at the age of 40 years, and the patient died at the age of 70. He suffered from movements of the face and limbs, but no mental symptoms were present.

No. 5.—Female, the daughter of the eldest brother of No. 4. Movements began at the age of 10 years and continued until her death at the age of 25 in childbirth.

No. 6.—Female, the sister of No. 5. Twitching and movements began between the ages of 10 and 12 years and have continued since, the patient now being 30 years of age and living abroad. It is very doubtful if in either of these sisters the condition is Huntington's chorea; it is quite likely to be one of conversion hysteria. The occurrence of such a release phenomenon in a family, the members of which are subject to Huntington's chorea, however, is worthy of note. It was further ascertained that a member of the same generation, a female, the daughter of No. 4, was deaf and dumb in childhood, but so far has developed no signs of the disease.

No. 7.—Male, the only child of No. 3 who survived to adult life, and the father of the two patients described in this paper. He developed movements at the age of 44 years, coincident with a period of domestic anxiety. He became steadily worse until the age of 49, when he was relieved of his employment, "as his health was unequal to the work." He then became rapidly worse and was soon almost as bad as his mother, who was then 81 years of age and died soon after. He continued in a business of his own until he was 54, but it was always a worry and a trouble to him. He was constantly falling about and hurting himself. Up to the age of 50 he had contortions of the face and limbs, but was not difficult to manage. After that age, however, he had many fits of passion and it was practically impossible to do anything with him. This state of affairs continued for several years. He was continually threatening to commit suicide, and would go away from home on every possible occasion, once being found in a police station and on another occasion falling off a station platform on to a railway line. It was apparent to his relatives that his mind was becoming deranged. He was certified at the age of 57. During the following year he was exceedingly troublesome, but later became quieter. He collapsed suddenly and died at the age of 59.

Clinical Commentary.

In the first patient movements of the face and limbs appeared between the ages of 35 and 36 years, and when the patient came under observation the character of the movements left little doubt that the condition was Huntington's chorea. This opinion was supported by the presence of grimaces, explosive speech, and a grotesque gait, and by the knowledge that the patient's father and paternal grandmother had suffered from the same condition. About five years after the onset slight evidence of mental impairment appeared, in that the patient became unduly excited over trifles. During the next five years the mental condition deteriorated very little. Some degree of dementia, however, supervened during the eleventh year of the illness. The patient's intelligence and perception were limited, her attention was difficult to hold, and her recent memory was poor. An interesting feature of her condition was a tendency to repeat phrases and sentences several times, during which it was impossible to introduce anything else to her attention. This tendency to repetition was apparently of the nature of perseveration rather than the type of word repetition known as palilalia and occurring sometimes in association with post-encephalitic Parkinsonism and bilateral lesions of the pyramidal tracts.

In the second patient the diagnosis was much more difficult, and in fact, apart from the family history, would have been impossible for five years. The patient was first seen at the age of 45 years with symptoms which indicated that a degree of mental deterioration was present, and suggesting a diagnosis of dementia paralytica. This condition, however, was excluded by the negative results of examination of the cerebro-spinal fluid. An involutional psychosis could not be excluded apart from the family history. The patient's mental condition slowly but steadily deteriorated for four years, when grimacing, explosive speech, and rigidity of the limbs appeared and confirmed the diagnosis of Huntington's chorea, in which dementia alone had at first been present. At this stage rigidity of the limbs of the extrapyramidal type was present, more on one side than on the other, and to a greater degree than in the first patient; perseveration of speech and action was even more pronounced. Also, there was present the same exclusion of everything else from the field of attention until the repetition of the word, phrase, or action had ceased.

Davenport has drawn attention to certain "biotypes" of the disease, all of which are comparatively rare. One of these is illustrated by the second patient, in whom dementia alone was present for four years before the choreic movements appeared. Such a variation of the disease may lead to serious difficulties in diagnosis. In the second "biotype" mentioned by Davenport, that in which the movements are present without any dementia, diagnosis is not so difficult. In fact, in many cases, chorea may be present alone for some years before the onset of dementia—a sequence of events which is the usual feature of the disease. In the first patient chorea only was present for five years, and then for a further period of five years

the evidence of mental deterioration was still rather indefinite. A better illustration of the second "biotype" is a member of a previous generation of the family (No. 4). In this patient, a male, movements were present for thirty years—from the age of 40 until death at the age of 70—and no mental symptoms appeared. A third "biotype," that in which the disease appears early in life, might be suggested by two patients in the third generation (Nos. 5 and 6). As, however, it has not been possible to obtain access to these patients, it is difficult to decide whether they had suffered from Sydenham's chorea at the age of 10 and the movements had persisted as a mimesis, whether they suffered from a conversion hysteria as a result of maladaptation due to a slight defect of mentality, or whether they suffered from a true "biotype" of Huntington's chorea. The fact that the latter disease had not affected either of their parents would suggest, however, that one of the former conditions was present.

An anatomical feature common to the two cases recorded was the presence of an extrapyramidal type of rigidity, presumably as a result of the partial release of the postural reflex path from cortical control. In the first patient it was comparatively slight; in the second patient it was extreme on the side on which the choreic movements were most pronounced, and present in lesser degree on the side unaffected by the movements. It would appear, therefore, that although the lesion usually affects the basal structures responsible for the conduction of the afferent impulses controlling voluntary movements, it may affect other basal structures first and produce some degree of extrapyramidal rigidity before the onset of choreic movements and dementia.

Commentary on the Family History.

An investigation of the family history of the patients revealed the presence of five other definite cases of Huntington's chorea in the two previous generations. There was no information available about the history of the family outside the three generations. In the first generation one male and two females were affected. The former died unmarried, while each of the latter transmitted the disease to one son. There was no evidence of the occurrence of the disease in the offspring of the unaffected members of the family, apart from the two doubtful cases (Nos. 5 and 6). In the second generation only two males were affected. The first male (No. 4) did not transmit the disease, but the second male (No. 7) transmitted it to two daughters. It might appear that the disease, which affected both males and females in the first generation, affected only males in the second generation, and only females in the third generation. This observation is, however, invalidated by the fact that in the second generation none of the female offspring of those affected in the first generation survived long enough to develop the disease. It is interesting to note, however, that in one branch of the family an affected female transmitted the disease to a male, whose daughter was deaf and dumb in childhood; while, in another branch, an affected female transmitted it to a male, whose two daughters were later affected. There is some evidence that the disease may predominate alternately in males and females in successive generations. It is reasonable to expect, therefore, that any male children of patient No. 8 might have become affected if a dominant antichoreic factor has not overcome what is possibly a recessive tendency to the disease, as it appears to have done in the other branch of the family. Apart from such speculations in the family studied, there is insufficient evidence upon which to correlate the method of inheritance with the known laws of heredity.

Of the seven definite cases of the disease in this family, the lowest age of onset was 36 years, and the highest 59 years, the age of onset in the other cases varying between these two limits. Of these cases, five followed the usual course of choreic movements upon which dementia eventually supervened; one suffered from movements without dementia, and one suffered from dementia for four years before the onset of choreic movements. The three affected members of the first generation survived to over 80; the two in the second generation died at 70 and 59 years respectively; while the two affected members of the third generation are still alive at 50 and 46 years of age. It is interesting to note that while the tendency to the disease is apparently becoming less in successive generations, probably as a result of the dilution of the strain, the duration of life of those affected is apparently becoming shorter, possibly because of the concentration of the toxic factor in those affected.

Summary and Conclusions.

1. Two cases of Huntington's chorea are described in detail, the clinical course in one approximating to the classical type and in the other characterized by the presence of dementia for some years before the appearance of choreic movements.

2. The family history has been investigated for three generations, and notes on five further cases of the disease added.

3. The clinical features are discussed and attention is drawn to the fact that two important variations of the disease—namely, dementia preceding chorea, and chorea without mental symptoms—have appeared in two generations of this family.

4. The family history is discussed and attention drawn to the following points: (*a*) the transmission of the disease only through affected individuals; (*b*) transmission through both males and females; (*c*) an apparent tendency to the transmission of the disease alternately through males and females; (*d*) the association of a lessened tendency to the disease in successive generations with the appearance of deafness and dumbness in childhood, and what may be psychoneurotic states; and (*e*) an apparent lessened expectation of life in those affected in successive generations.

X-RAY TREATMENT OF THE COMMONER MICROBIC DISEASES OF THE SKIN.*

BY

J. B. HIGGINS, M.B., CH.B., D.M.R.E.,

HONORARY RADIOLOGIST, SALFORD ROYAL HOSPITAL.

In the words of a dermatologist of world-wide reputation, the history of *x*-ray therapy in relation to diseases of the skin may be divided roughly into three eras—namely, the optimistic, the pessimistic, and the realistic. This analysis appears to form an accurate, if somewhat cryptic, description of the progress of *x*-ray treatment since its inception about the year 1896. The results obtained by the earliest workers were regarded at that time as bordering on the miraculous. Then followed a series of mishaps and a few disasters, which soon brought considerable discredit on this new form of treatment. This eventually led to a careful investigation into the effects of *x* rays on the normal and pathological skin, improvement in apparatus, and more reliable methods of dose estimation, until at the present time *x*-ray therapy ranks as one of the most reliable factors in the treatment of many skin diseases.

To-day we are concerned particularly with the *x*-ray treatment of the more common microbic diseases of the skin, and I propose to discuss briefly the methods employed in the *x*-ray department of the Manchester and Salford Hospital for Diseases of the Skin which have produced satisfactory results.

The application of the rays in the group of diseases under discussion varies considerably, and depends chiefly on the nature of the infection and the condition of the skin at the time of treatment. The rays when they are absorbed into the skin produce certain biological changes in each of the individual cells exposed to them. These changes, according to Hertwig, are supposed to be due mainly to molecular dissociation of colloidal albumins by the secondary rays which are generated when the primary rays strike the body cells, the process being analogous to dissociation of gases by means of ionization. Packard, on the other hand, has evolved a theory which states that control of the mechanism of the living cell is carried out by certain substances called enzymes, which are present in every cell, and concerning which we know very little.

* Read in opening a discussion at a joint meeting of the Sections of Dermatology and Radiology and Radio-Therapeutics at the Annual Meeting of the British Medical Association, Manchester, 1929.

Thus a certain dose of the rays will increase the activity of the enzymes and through their agency stimulate the metabolism of the cell. A rather larger dose will inhibit the action of the enzymes and render the cell inactive. Still larger doses cause destruction of the enzymes, thus resulting in the death of the cell. Recently Holzknecht, Caspari, and others have denied that *x* rays have any direct stimulating effect, and prefer to regard any stimulating effects which may occur as due partly to the results of the early changes which precede injury, and partly to the indirect results of the suspension of inhibitory influences in the cell. Whichever view one may take, however, the undeniable fact remains that small doses of *x* rays have a decidedly stimulating effect on certain skin diseases, of which acne vulgaris is a striking example.

The most essential factor in the treatment of microbic skin infections is a thorough appreciation of the degree of sensitivity of the skin in its normal state and in its various pathological conditions. The greater sensitivity of the diseased cells which is invariably present permits an effective dose to be given to them without injury to the surrounding healthy skin. The only effect on the latter will be of a mildly tonic stimulating nature.

In the presence of hyperaemia accompanying the pathological condition, however, such as is found in many cases of sycosis, the question of suitable stimulating doses becomes more complex, as we are dealing with a skin which is no longer normal, but which has become definitely hypersensitive. Thus the margin between stimulation of the affected cells and injury to the surrounding hyperaemic skin becomes considerably narrowed.

The diseases of the skin which come under the heading of "commoner microbic diseases" are as follows: acne vulgaris (and indurata); sycosis vulgaris; paronychia (due to pus-forming organisms); furunculosis (including carbuncles).

ACNE.

The type of acne with which the radiologist most frequently comes into contact is acne vulgaris (including acne indurata). In this so-called microbic infection it is now generally agreed that *x*-ray treatment is the method of choice, in that a satisfactory result can be obtained safely and more rapidly than by purely medical means. It is not, however, suggested that *x* rays are indispensable in the treatment of this condition, as cases of very mild acne are cured without its aid, while some workers prefer the use of ultra-violet radiation.

The apparatus used at the Manchester Skin Hospital consists of a 16-inch coil. The rays are emitted from a Coolidge tube and are of the quality produced by a kilovoltage of approximately 120 and a milliamperage of 3½, or in other words a collection of soft and medium rays at an equivalent spark-gap of 6½ in. Working under these conditions it has been found that an erythema dose estimated by the use of the Sabouraud pastille can be produced in approximately two minutes at an anticathode skin distance of 8 inches.

Dosage has usually consisted of a preliminary course of three or four half skin doses unfiltered, and administered at an interval of seven days between each dose. Following this a similar course has been given, but a filter of 0.5 mm. of aluminium is used. The following table shows the dosage administered in a series of 37 consecutive cases of acne vulgaris (15 males and 22 females) treated recently.

Table showing Number of Treatments in 37 Consecutive Cases of Acne Vulgaris.

Acne of Face.				Generalized Acne.	
Males.		Females.			
No. of Cases.	No. of Treatments.	No. of Cases.	No. of Treatments.	No. of Cases.	No. of Treatments.
1	3	3	3	1	5
2	4	4	4	1	10
1	5	8	5	3	12
2	6	3	8	1	13
1	7	2	10		
3	8				
1	9				

Of these, 31 constituted affections of the face, and 6 generalized acne—that is, involving the face, back, and chest. The average age of the males was 18.3 years, that of the females 22 years.

The total dosage varied between three and ten treatments, each consisting of three or four half skin doses unfiltered, and followed by the remaining doses with the use of a 0.5 mm. aluminium filter. In one case, however, only one-third pastille doses were given, while in two cases a 1 mm. filter was employed following the initial unfiltered dosage. Of the 31 cases of acne of the face the results in 4 were indefinite, though there is no actual record of failure in any of those treated. Two of the 6 cases in which the back and chest were involved showed indefinite results, while one failed to respond satisfactorily after thirteen treatments.

Several methods differing in detail from that just described have been employed by various workers. These constitute differences in the doses administered and in the use of filters. The methods of MacKee on the one hand, and of Arzt and Fuhs on the other, show appreciable differences in their employment of filtration. Both use rays of medium quality and advise the employment of fractional doses, though MacKee uses a quarter skin dose and gives a preliminary course of sixteen treatments at intervals of seven days between each. In stubborn cases, in the absence of erythema or wrinkling of the skin, he considers it permissible to continue treatments for two additional months. If a cure is not effected after six months it is advisable to discontinue *x*-ray treatment. He also states that while it is possible to cure a case of acne vulgaris in one or two treatments by giving at one sitting a quantity sufficient to produce an erythema, such treatment cannot be criticized too severely.

Arzt and Fuhs employ a filter of 1/2 to 1 mm. of aluminium and administer doses of two-fifths of a skin dose. Three or four treatments are given at intervals of ten to fourteen days. After an interval of four weeks the whole cycle may be repeated, and after a further period of eight weeks, still a third cycle, the whole extending over thirty-two weeks. In deep indurated cases they advocate three-fifths skin doses through 2 mm. aluminium from the commencement.

Most dermatologists and radiologists will agree with MacKee that large initial doses in the treatment of acne are both inadvisable and unnecessary. The individual doses used in the present series are certainly larger than those employed by him, but in order to avoid any risk of erythematous changes a 0.5 mm. filter of aluminium is used after the third or fourth treatment.

Comparison with the total dosage administered by MacKee and Arzt and Fuhs shows that the former gives a total of four to six skin doses, while the latter give a total of six to eight skin doses. The present series shows that an average of five to six skin doses in each case is required to produce a cure. Thus it would appear that the curative effects of *x* rays on acne depend not so much on the degree of filtration, or quality of the rays employed, as on the total quantity of the latter which are absorbed by the skin. Any attempt to standardize skin dosage in terms of quantitative absorption, however, is to be deprecated, for the actual amount of absorption required to produce a cure depends on two important factors; these are, the type of skin to be treated, and the interval between treatments. It is a generally accepted fact that the skin of a blond will respond more readily—or, in other words, absorb the rays more readily—than will that of a brunette, and considerably less dosage may be required to obtain the desired result. It should also be remembered that the shorter the interval between treatments the greater will be the cumulative effects of the rays. If there be any advantage in the method of treatment employed in the present series, it lies in the fact that most cases can be cured in approximately seven or eight weeks, with no ill effects.

As previously mentioned, it is believed that fractional doses of *x* rays act on the pathological skin cells through the stimulation of their controlling mechanism, and it has been supposed that in cases of acne the affected cells are stimulated to resist the influence of the infecting

organism, and, in successful cases, to cause its death. On the other hand, it is possible that inhibitory influences appear in the infected cells. In this way the organism becomes deprived if its nutrition and dies.

Whether the rays act directly on the bacillus itself was until recently a matter of considerable controversy. Investigators have varied widely, in that some authors believe there is a good bactericidal action, others note stimulation effects, while still others observe certain biological changes. In 1912 Chambers and Russ succeeded in sterilizing cultures of *Staphylococcus aureus* in suspension. For this purpose they used 0.5 millicurie of radium salt per cubic centimetre of the medium. Kloverkorn in 1925 carried out experiments on the bactericidal and retarding actions of *x* rays on *B. coli* and *Staphylococcus aureus*. Freshly grown cultures on agar were not killed after the administration of 120 skin doses. With 50 skin doses and upwards colonies exhibited biological changes, such as loss of pigment and irregularity in the colony outline, as well as inhibition of growth. The actual death of these organisms, however, was only accomplished in cultures twenty-eight days old, and with 120 skin doses.

In view of these experiments it may be said with safety that the bactericidal action of *x* rays, as used in the treatment of acne, is nil, while any inhibitory effect on the growth of the bacillus which might occur may be regarded as negligible. On the contrary, it has been my experience that doses up to eight skin doses result in stimulation of freshly grown cultures on agar of *Staphylococcus aureus*.

Sycosis.

Sycosis, as the result of a microbic infection (sycosis vulgaris or sycosis pyogenica) is a condition which presents peculiar difficulties in its treatment. As we know, this form of sycosis manifests itself in the appearance of a number of small red papules arising from the hair follicles of the beard. These may remain localized, with comparatively little inflammation around them, or may spread rapidly and become closely aggregated. Coalescence of the papules may result in the formation of crusts, and may be associated with marked hyperaemia. The lesions also vary considerably in their distribution, and may be limited to two or three small patches, or may involve the whole of the hair-bearing area of the face and neck.

The factor of vital importance in the treatment of this condition may be summed up in the one word "hyperaemia." Hyperaemia is almost invariably associated with sycosis, and may vary from a negligible degree to one of generalized acute inflammation. Thus one is dealing with a hypersensitive skin, which will respond to a given dose of *x* rays in proportion to its degree of inflammation. A real difficulty, however, arises in the fact that one cannot determine with certainty the exact degree of the response to be expected. Even normal skins show slight variation in sensitivity to the rays, a feature which becomes considerably magnified in the presence of inflammation.

Three methods of treatment are open to the radiologist: (1) epilation of the beard; (2) stimulation of the affected cells; (3) a combination of these two methods.

It is impossible to lay down any hard-and-fast rule in the choice of method to be employed, as each individual case varies and must be judged on its merits. There are, however, certain general principles which must be observed if one is to avoid disaster. The acutely inflamed skin, such as is found in a mixed infection, should on no account be treated until some successful effort has been made by other means to reduce the hyperaemia, and even then the early administration of a dose sufficient to produce epilation is attended with grave risk. In such cases we are left with the alternative of administering very small stimulating doses—actually not more than a one-third skin dose at weekly intervals. In cases of moderate hyperaemia stimulating doses are again the rule, though, the skin being slightly less sensitive, it is usually safe to administer half skin doses. It is frequently found that cases of the inflammatory type treated by the above methods show very marked improvement. The greatest success from the radiological point of view is obtained in those cases which show practically no hyperaemia. The dosage may be carried to the point of epilation, which appears to constitute the ideal method of treatment. Such cases, if complete epilation is effected, can often be cured rapidly by other means.

A series of 36 consecutive cases of sycosis were examined, but owing to the fact that x-ray treatment formed only a small proportion of the total treatment administered, no very helpful conclusions can be drawn. It is worthy of note, however, that of these 36 patients, 10 received single epilating doses, 9 of whom were cured, while the average total duration of treatment was two months. Of the remaining 26, 15 received half skin doses, and 6 one-third skin doses. In one case epilation was successfully accomplished with a three-quarter skin dose on a mildly hyperaemic skin, while in one other case a two-thirds skin dose failed to produce epilation.

It has been our experience that mild stimulation of the infected beard produces marked improvement in the majority of cases, though as long as the infected hairs remain we cannot hope for a cure through the medium of *x* rays alone. A rather remarkable result was experienced quite recently.

The case was that of a man who had sustained severe burns on the greater part of the face. When first seen, two years later, the latter was a mass of scar tissue, with the exception of the under part of the chin and a small area on the left cheek. These two areas, together with the one eyebrow which still remained, were infected with sycosis. Two small ulcers were present in the scar tissue itself, while the whole face showed an appreciable degree of hyperaemia. Epilation was quite out of the question, and it was eventually decided to give small stimulating doses. Three one-third skin doses were administered, two of which were given through a 0.5 mm. aluminium filter. After a lapse of six weeks, during which time he had carried out medicinal treatment, the patient again reported for inspection, and the response had been remarkable. The ulcers had healed, and there was practically no trace of the previous infection.

This case is of particular interest in that no attempt had been made to produce epilation, yet there appeared to be a vast improvement in the condition.

A case of supposed spontaneous cure has also occurred in my own experience.

The patient, a man of about 35 years of age, was suffering from a mild sycosis of the beard, with practically no hyperaemia. Epilation was attempted, and the patient was again seen one month later. Examination revealed that, in spite of the fact that no epilation had occurred, the condition had cleared up completely, and there has been no recurrence.

We are quite unable to understand this result. It is just possible, however, that this patient had inadvertently received rays from an unduly hard tube, that the majority of the rays, being hard, penetrated the superficial layer of the skin and stimulated only its deeper cells. Owing to the small proportion of soft rays insufficient were absorbed during the time of exposure to produce epilation. This theory, however, is by no means a complete explanation of what must be regarded as a spontaneous cure.

It is our practice to treat sycosis, except in very few cases, without the use of filters, a proceeding which it must be admitted is open to criticism, particularly in those cases which exhibit marked hyperaemia. While no ill effects result from administration of such small stimulating doses, and though considerable improvement may result, it seems quite reasonable to assume that the use of a thin filter—for example, 0.5 mm. of aluminium—would allow the administration of rather larger dosage without fear of untoward results. I have not had the opportunity of comparing the respective merits of these methods, but other workers have long used varying degrees of filtration. Some therapeutists, indeed, go to the length of producing epilation of the beard through a filter of 2 mm. of aluminium. This method does not appear to be entirely satisfactory, requiring as it does considerably larger doses than by the unfiltered method. Moreover, it is liable to result in unpleasant consequences, such as temporary paralysis, and occasionally swelling of the salivary glands.

The results obtained in the treatment of paronychia by *x* rays have not proved very encouraging. Six cases have been treated during the last two years, and of these only two were definitely cured after the administration of eight half skin doses to each. The results of two were indefinite, while two were not cured at the end of seven months and ten months.

I have had practically no experience of the treatment of furunculosis and carbuncles, though other workers seem to have experienced good results, particularly in the former condition.

Schreus has noticed that irradiation of boils in one area (one and one-fifth skin dose with 2 mm. aluminium at 20 cm. anticathode skin distance) has resulted in gradual decrease of the number of fresh ulcers appearing in other parts, until finally the condition has cleared up entirely. He suggests that the changes in the irradiated skin are probably due in the first place to the destruction and absorption of the staphylococci and diseased tissue cells. This tends to result in a form of auto-vaccination, with the production of specific protecting bodies, and the creation of some degree of resistance and immunity. This so-called immunizing action of the rays may be further reinforced by the use of autogenous vaccines.

Supersoft Rays.

In conclusion, the recent work in the treatment of skin diseases by means of supersoft rays is of such importance that this paper would be incomplete without a brief reference to this method of treatment.

Several experiments by Bucky and others have been carried out in this field, dating from 1912, and have culminated in a paper on "Supersoft Röntgen rays in dermatology," by J. J. Eller, which was read before the New York Röntgen Society in 1927. These rays were produced by means of a specially constructed transformer unit and a Müller tube, and were of the length produced by a kilovoltage of 8 and a milliamperage of 8. One unit dose was considered the dose which was necessary to produce a mild erythema within twenty-four hours at an anticathode skin distance of 6 cm. Working under the above conditions this was accomplished in three minutes.

It is claimed that the use of supersoft rays has certain advantages over the rays of shorter wave-length in general use. Supersoft rays are similar to medium x rays in that they produce an erythema, have penetration, may produce pigmentation, and have cumulative effects from successive treatments. They differ from the biological effects of harder rays in that erythema may appear almost instantaneously—that is, within two or three hours, or even less (compare three days to fourteen days with harder rays). Penetration of supersoft rays is much less, hence one or two erythema doses can be given without temporary or permanent epilation.

Following larger doses Schultz reported cases in which actual ulceration occurred. These ulcerations were painless and healed without atrophy of the surrounding skin after fifteen months. No atrophy of the skin, telangiectases, or malignant manifestations have been noticed two years after marked erythema doses, though these, of course, may appear later on.

Among many skin diseases treated, mention is made of acne vulgaris. The results of treatment in this condition were not particularly good, certainly no better than by the present-day methods of treatment. Good results, however, are reported in the case of sycosis, paronychia, and carbuncles.

This method of treatment by supersoft rays is at present in its infancy, but it will—in the opinion of workers in this field—ultimately find an important place in the treatment of dermatological conditions. It is believed, however, that these rays will never replace entirely the medium rays as used at the present day.

RECTAL ETHER-OIL ANAESTHESIA, WITH SPECIAL REFERENCE TO BRAIN SURGERY.*

BY

WINIFRED WOOD, M.B., CH.B.ED.,

EDINBURGH.

It is surprising to find that the administration of ether per rectum was first described as early as 1847. The method employed then and up to about 1910 was that of pumping ether vapour into the bowel, and, though the results were encouraging, the method was acknowledged to be more complex than that of ordinary inhalation anaesthesia.

The properties and action of ether in oil per rectum were first investigated by Dr. Gwathmey of New York, who read a paper on the subject in London in 1913, since when this method of administration has been taken up and proved by many anaesthetists. Dr. Gwathmey himself inspired me to try this method, and during the past two years I have used it in over seventy cases, using a modification of his technique.

The uses of rectal ether-oil in general surgery are very wide, and its very safety has made it the anaesthetic of choice in all bad surgical risks in my hospital practice. But for the lack of time I would use it far more extensively. Of the cases selected for the use of this method I have records of umbilical hernia, cholecystectomy, cholecystostomy, exploratory laparotomy, nephrectomy, appendicectomy, total and subtotal hysterectomy, and breast operations. The method was employed on account of the following conditions: debility, extreme nervousness as in hyperthyroidism, obesity, heart conditions with failing compensation, chronic lung conditions, and anaemia.

It will be seen from the range of operations quoted and the relative seriousness of the conditions which determined the choice of a rectal anaesthetic that this method should have a wide application in operations which impose a prolonged strain on the patient. In looking over a series of more than fifty cases of brain operations I am quite convinced that in this particular branch of surgery rectal anaesthesia is invaluable.

Before going on to a description of the technique used in brain surgery I should like to mention what appear to me to be a few of the advantages of this method. First, in a brain operation access to the patient's face is necessarily difficult owing to the position and towels, etc.; this makes an inhalation anaesthetic difficult to administer, particularly if the patient does not tolerate ether vapour well. Under a rectal anaesthetic it is not necessary to look at the patient's face, if in the original position his airway is quite clear. The quiet even breathing makes it very rarely necessary for the anaesthetist to interfere, as the jaw is not sufficiently relaxed to obstruct the air passages. Secondly, the dose of ether compares very favourably with the amount used by any inhalation method. Six ounces of ether will give a four hours' anaesthesia. I do not know exactly how much ether I have used in giving a similar length of anaesthetic by intrapharyngeal ether vapour, but it is nearer 16 ounces. Thirdly, while the patient is under the influence of rectal ether the anaesthetist has time to take observations and to chart them during operations. In all brain cases I have records of the systolic and diastolic blood pressure, pulse, and respiration taken every ten minutes. The stage of operation is noted and correlated with these. The chart is completed with an account of the induction and all the pre-operative drugs and the amount of anaesthetic. This record forms a very valuable indication of the patient's condition during operation and is a guide as to how far the operation may proceed without undue strain on the patient. Operative shock can be detected in its earliest stages and treated accordingly.

Technique.

The ordinary rectal ether-oil technique has to be adapted to these brain operations, owing to the length of time which the operations take and to the special conditions which exist.

The actual technique of administration of the mixture per rectum is exactly the same for brain work as for general surgery, but for the fact that morphine in any form is strongly contraindicated because it tends to congest the tissues of the head. This unpleasant fact changes the whole picture. It is comparatively simple to give a rectal anaesthetic with morphine, but it is a very difficult matter without it, owing to the varying effect of ether on the individual.

The technique which I am going to describe is fairly constant, and is the outcome of work on over fifty cases.

* A paper read in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

Pre-operative Treatment. The preparation of the patient is almost the same as that of any case for surgical treatment. Two days before operation an aperient is administered. The day before operation the patient is kept on light diet, an enema is given in the morning and a bowel wash-out in the evening. The important point is that all preparation should be done in time to enable the patient to have a good night's rest.

The Day of Operation.—One and a half hours before operation the patient receives the first rectal injection; this consists of chloretone 20 grains, ether ½ oz., paraldehyde 2 to 4 drachms, paraffin 1 oz. Forty-five minutes before operation he receives the second rectal injection; this consists of a 75 per cent. mixture of ether in paraffin. The maximum dose is administered—that is, ether 6 oz., paraffin 2 oz. Atropine is given as a routine in case it is necessary to use any supplementary ether vapour.

The patient is usually drowsy before the time for the second rectal injection; he may even be sound asleep. If this is the case it is a fairly easy matter to run in the mixture, which is generally well tolerated, in about ten minutes. Towards the end of the second injection the patient may complain of the taste of ether; he will be sleepy in twenty minutes from the time of the beginning of the injection, asleep or possibly analgesic in thirty minutes, and anaesthetic in forty minutes. These times vary considerably in different patients.

In patients who have discomfort and even pain and difficulty in retaining the second rectal injection, I find it a good plan to give a few drops of chloroform on a mask at the same time as the ether mixture is being run in. It is surprising how quickly they go to sleep. The ether mixture can then be run in quickly, and the chloroform sleep seems to last till the ether takes effect. There is very rarely any excitement during induction.

It must be understood that rectal anaesthesia is a *controlled anaesthesia.* In suitable cases and wherever possible the rectal injection of ether alone is relied upon to produce sufficient depth of anaesthesia. Ether, like other drugs, affects various individuals differently, and one is never able to tell beforehand whether more anaesthetic will be necessary. It is my custom to supplement the rectal ether with intrapharyngeal ether vapour. There are many other methods of control, but under the conditions obtaining in brain operations this is the most convenient. It is rarely necessary to give the ether vapour throughout the entire operation. The pre-anaesthetic medication, chloretone-paraldehyde, etc., does in one sense control the anaesthetic, or rather tends to intensify the action of ether, and certainly prolongs the post-operative period of sleep.

Type of Anaesthesia.

The anaesthesia produced by the injection of rectal ether is very light; sometimes it amounts only to an analgesia. It has been proved that, whatever the oily vehicle, the rate of absorption of ether is the same, about one and a half to two ounces being absorbed in an hour. This even absorption of ether from the bowel produces a perfectly smooth anaesthesia without danger of overdosage. The patient presents a typical picture. He appears to be sound asleep, the face is slightly flushed, the breathing is quiet but audible, the jaw is seldom so much relaxed that the breathing is obstructed, but an airway is well tolerated. The pupil reacts briskly to light, and the amount of dilatation gives a very good indication of the depth of anaesthesia. The pulse is slower than in an inhalation anaesthetic. Slight movements may occur, but if the relaxation is sufficient for the surgeon's purposes these do not indicate that the patient is too lightly anaesthetized.

Ether given in this way seems to have very little effect on the blood pressure, even after prolonged administration. There is generally a slight rise of the systolic blood pressure when the ether begins to be absorbed, but it tends to remain very steady throughout the many hours of actual operation, provided there is no sudden haemorrhage or pre-existing intracranial tension. If the blood loss is slight and continuous over a long period there will be a gradual fall in pressure till the main part of the operation is done. During the closure of the head, which may take one to two hours, the blood pressure tends to rise, and at the end may be the same as at the beginning. Most of the variations in blood pressure are due to the operative procedure and to existing conditions, such as high intracranial tension. If a patient is troublesome at first, requiring more anaesthetic than is usually necessary, and has a varying systolic blood pressure which tends to be high, it will generally be found that the intracranial pressure is the cause of the difficulty. After tapping the ventricles, cisternal puncture, or opening of the dura he will generally settle down well. It may be necessary to tap the ventricle at an early stage in the operation to obtain a satisfactory state of affairs.

It stands to reason with this method of administration that there is little if any interference with the proportion of oxygen and carbon dioxide in the inspired air. The quiet breathing in itself demonstrates the fact that the carbon dioxide is not increased sufficiently to affect the patient.

It is important that the metabolism of the patient should be disturbed as little as possible in a brain operation, when his staying power is, in some cases, taxed to the uttermost, and I venture to state that a rectal anaesthetic gives rise to less disturbance than an inhalation anaesthetic of a prolonged type. I have no scientific proof to give, but I draw my conclusions from the study of records and from the post-operative condition of the patients.

Post-operative Clinical History.

It is most noticeable in the period immediately succeeding operation that the patient's colour is good, the pulse and general condition are very satisfactory, and the look of exhaustion so often seen after severe operations is not present. There is a period of quiet sleep, which lasts from two to four hours or more, and there is seldom any vomiting. I have never seen any respiratory complications directly attributable to a rectal anaesthetic even in elderly patients. In all the cases of rectal ether that I have done I have seen only one with some irritation of the bowel and slight haemorrhage. Whether this was due to pre-existing disease I do not know. Haemorrhoids are not a definite contraindication to the administration of rectal ether, but they are apt to be painful during the injection of the ether and oil. The preparation by enema and wash-out probably tends to congest the bowel, and therefore makes the haemorrhoids more painful.

To illustrate various points I have made I would like to record two or three cases in which rectal anaesthesia only was employed.

CASE I.

The patient was a woman aged 44

First Operation.—Lateral bone-flap and decompression. Time occupied three and a half hours. The systolic blood pressure, which before operation was 140, after transfusion fell to 115, but at the end of operation had risen to 135.

Second Operation (six days later).—Removal of tumour. Time three and a half hours. At the beginning of operation the systolic blood pressure was 140, during the operation it fell to 110, and at the end was 115. There was no transfusion during this operation. Five hours later the temperature, pulse, and respirations were normal

CASE II.

A woman, aged 53, was operated on for the removal of a meningioma. The time occupied by the operation was six and a half hours. The amount of ether used was 9 ounces. The systolic blood pressure was 140 at the beginning of operation, throughout which there was considerable haemorrhage, so that the patient had to be transfused twice; the blood pressure fell to 102, but at the end of the operation it had risen to 128. Respirations were steady at 28, the pulse was very irregular but never rose above 120. Five hours after operation the temperature was 98.4°, pulse 88, and respirations 22, the systolic blood pressure was 112.

CASE III.

The patient was a man aged 65. Operation consisted of a frontal bone-flap and removal of a suprasellar cyst. The time occupied by the operation was four hours. The patient seemed older than his years and his normal blood pressure was low. At the commencement of operation the systolic blood pressure was 112; it fell to 100, at which it remained at the end. The patient made an uneventful recovery, he was up in ten days, and out of the home in a fortnight.

Conclusion.

I have not attempted to prove anything in this short description, but I hope I have conveyed the impression that rectal ether-oil is a safe and very easily controlled anaesthetic, which through its very safety can be given to bad surgical risks, and will leave the minimum of bad effects in cases involving many hours of operating, and which, above all, gives the anaesthetist a quiet mind.

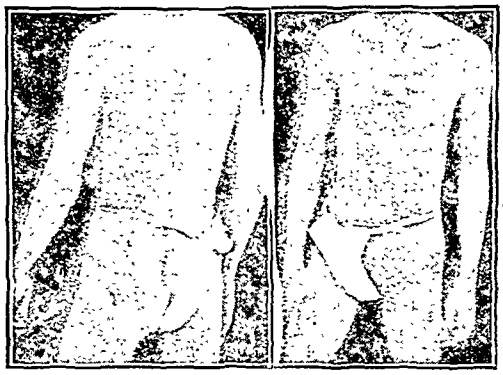
Memoranda:
MEDICAL, SURGICAL, OBSTETRICAL.

COEXISTENT HERPES ZOSTER AND VARICELLA.

RECENTLY attention has been drawn to an apparent connexion between herpes zoster and varicella, and several correspondents have recorded cases in which herpes in one member of a family had occurred almost at the same time as varicella in another member. Although cases of the two diseases coexisting have been described, the onset is as a rule not simultaneous, and therefore I feel that the following notes may be of interest.

A male Chinese, aged 36, was admitted to Tan Tock Seng Hospital on August 5th, complaining of a painful eruption on the left buttock and inguinal region of three days' duration.

On examination he was found to have herpes zoster affecting the above-mentioned sites, the posterior root ganglia of the last



thoracic and first lumbar nerves being implicated. In addition, there were varicella vesicles, in varying stages of development, on the trunk and face. The patient had tried the effect of some Chinese medicine on the buttock, and this has caused several bullae to appear.

The condition is shown in the accompanying illustrations. The vesicles on the trunk were touched with eosin in order to make them stand out more clearly.

Dr. C. C. B. Gilmour of the Middleton Hospital for Infectious Diseases in this city tells me that about six months ago he saw an instance of the coexistence of the two diseases in one patient. In his case the herpes affected the right side of the chest and axilla, while the varicella vesicles were much more numerous than in my patient.

I am indebted to Hon. Dr. A. L. Hoops, principal civil medical officer, Straits Settlements, for permission to record this case.

J. M. A. LOWSON, M.B., Ch.B.St. And.,
Medical Officer in Charge, Tan Tock Seng Hospital, Singapore.

HERNIA OF THE UTERUS IN AN INFANT.

IT is stated in the textbooks that any of the contents of the abdomen may at times be found in a hernial sac, but the following condition is, I believe, sufficiently unusual to be worth placing on record.

A female infant, aged 17 months, was brought to my consulting room at 10.30 p.m. with an irreducible right inguinal hernia about the size of a walnut. The hernia, which had never previously been larger than an almond, had been controlled by a rubber truss for about six months, but this had been left off a few days before owing to excoriation of the skin, and the swelling in the groin had been present since the morning. The child seemed well, had taken her food normally, and had her bowels opened, but had vomited several times during the evening. She did not greatly resent attempts at reduction, but as these failed she was admitted to the Finchley Memorial Hospital, and was operated on by Dr. W. S. Rooke.

After the escape of some fluid from the sac it was seen that the contents were the uterus and adnexa of both sides, the cervix uteri being firmly gripped by the internal abdominal ring. The right ovary was purple, but quickly regained its normal colour on relief of the pressure. The right broad ligament was continuous with the sac wall, and had to be dissected away from it before reduction was possible.

E. MARJORIE ROOKE, M.R.C.S., L.R.C.P.

London, N.12.

Reports of Societies.

HEAD INJURIES AND THEIR TREATMENT.

AT the meeting of the Medical Society of London on December 9th, with Mr. DONALD ARMOUR, president of the society, in the chair, the subject of discussion was "The treatment of head injuries."

Mr. WILFRED TROTTER, in introducing the subject, said that this was a very ancient branch of surgery. The operative opening of the skull was the oldest of known operations, and had been practised for many thousands of years. The subject, as the present surgical generation had received it, was not only founded on an immense body of experience and observation, but encrusted to a considerable extent with traditions which showed a remarkable power of survival. Surgery was thought of as essentially a progressive art. But in surgery ideas which once had a real or supposed validity survived long after the increase of knowledge had made them obsolete. An example might be cited from the junior branch of abdominal surgery. The doctrine that the peritoneum was excessively susceptible to infection was of vital importance in its time, but was superseded and disproved under the antiseptic method; nevertheless it lived on, and for many years ingenious and complicated methods of doing extraperitoneal operations were taught. In the surgery of head injuries one of the chief needs was a resolute overhauling of its inherited ideas. The difficulties of the subject were in any case considerable, and should not be increased by the retention of conceptions which had lost their validity or which involved needless obscurity and complication.

The subject of head injuries, Mr. Trotter continued, had developed in three stages—what might be called the early, middle, and modern periods. The first period extended roughly from the earliest times to the seventies of the last century. The middle period, covering the last quarter of the nineteenth century, was the period during which the subject attracted the attention of the experimental physiologist, and underwent very great advances in consequence. Subsequently there had been no very great extension of knowledge by experimental methods, but a distinct assimilation of the knowledge acquired experimentally with clinical experience. What had surgery inherited from these two earlier periods? The first period was dominated by one idea—that of fracture of the skull. That idea had been superseded by further knowledge and experience, yet it survived to-day, truly in diminished strength among the medical profession, but with unabated vitality in the lay mind, and especially in the legal mind. What, in the light of subsequent knowledge, was the significance of fracture in cases of head injury? The skull, although its most obvious characteristic was its rigidity, was, of course, also flexible and elastic to a considerable extent. When, therefore, violence was applied to it it yielded correspondingly, and in a local or general way according to the manner in which the force was applied. It was this distortion of the skull, as it might be called, which was responsible for intracranial injury. If the distortion was not sufficient to go beyond the limit of the skull's elasticity, the skull recovered its shape when the distorting force was withdrawn, and there was no fracture, although the brain might already have received serious damage. If, on the contrary, the limit of elasticity was exceeded, fracture occurred at the places where the distortion was most marked. When the external force was limited to a small area, the distortion and the fracture were local; when the force was more general, so were the distortion and the fissured fractures which resulted. The presence of a fracture made it probable, though not certain, that considerable distortion of the skull had occurred. It furnished, therefore, some rough measure of the violence to which the brain had been exposed. The absence of fracture was no evidence that the skull had not been considerably distorted and the brain seriously damaged. There was no longer justification in the investigation of head injury for regarding the question of fracture as being of the first importance. The amount of damage the brain had received must always be a matter for inquiry.

The phrase "fracture of the base of the skull" was not the only part of the inherited vocabulary which was open to serious question. Another inherited term was "concussion of the brain." Could there be a better illustration of the danger, when inventing a vocabulary in a progressive subject, of giving explanatory names instead of descriptive ones? The explanatory name might be very good for the time being, but sooner or later it was pretty sure to be superseded. It was always safer to keep to a name which was simply descriptive rather than one which conveyed a theory. The term "concussion" perpetuated the view that this remarkable clinical condition, this instantaneous traumatic paralysis which went by the name of "concussion," was produced by the shaking up of the brain inside the skull, resulting in some mysterious, though hypothetical, detriment. It could be stated categorically that that was untrue. It was known with reasonable certainty that the state of concussion was due to general anaemia of the brain which accompanied a general distortion of the skull. It was time that these inherited ideas were revised.

In the middle period of which he had spoken, when the subject of head injuries attracted the attention of experimental physiologists, a number of distinguished men investigated the problems which previously had chiefly depended upon clinical observation, and they did actually establish the principles of the cerebral circulation and the way in which the brain reacted to injury. Their work had not yet been fully appreciated or assimilated into practical surgery and medicine. That work furnished the essential *facts about the peculiarities* of the cerebral circulation, especially the importance of the venous side of it. Yet it must be admitted that the work had not resulted in as much progress on the clinical side as it seemed to promise. It was *probable* that the failure of the new knowledge on the physiological side to force itself into the clinical field was due to two things: first, to the fact that most of the exposition of the new material was unnecessarily obscure and complicated; secondly, to the domination during the whole of this middle period of the theory of a localized compressing lesion. If a local compressing focus developed in the skull, how did it affect the brain and cause the brain to give rise to abnormal symptoms? The student was apt to get the impression that the localized haemorrhage which lent itself to successful operative treatment was the *usual form* of head injury which he would be called upon to treat. Anybody who had practised considerably in head injuries was aware that that kind of case was very rare. Such cases did exist, and when they were encountered, thanks to the work of the experimental school, they were easily diagnosed, a clear understanding of their symptomatology was available, and they could be dealt with successfully. But they were very rare. For every single case of that kind *fifty cases* of a different type would be met with which *did not lend* themselves to these brilliant results. It was the duty of anybody working on this subject to *discourage* the prevailing *idea* that this condition was a common one.

In conclusion, Mr. Trotter mentioned a few leading characteristics of modern treatment. Modern treatment was no longer dominated by the idea that fracture of the skull was of *first importance*, or by the expectation of often meeting straightforward localized haemorrhages where a simple operation might be done. He thought the attitude of the modern surgeon towards head injuries included the conception that injuries were *produced by* distortion of the skull, and therefore, as anybody might guess, bruising was more common than lesions which produced haemorrhage. The probabilities were that the whole brain had been more or less damaged by bruising; it was possible that the vessels *had been divided and localized haemorrhage* produced, but the chances were that the surgeon's task would be to deal with an extensively bruised brain. The province of urgent operations was, therefore, exceedingly small. Most operations which seemed to be called for within twenty-four hours after an accident were either unnecessary or unsuccessful. The surgeon would realize that as he was faced with what was essentially a condition of extensive and even ultimately fatal bruising of the brain, he must deal with it by methods which were, on the whole, less dangerous than operation, and he would, at any rate primarily, make use of the remarkable series of remedies for increased intracranial tension which modern experience had placed *in his command*—such methods as posture, administration of salines, and lumbar puncture. Only in the last resort would he feel called upon in certain of such cases to operate.

Dr. GRAHAM HODGSON discussed the radiography of the skull *in relation to fractures*. In the *x*-ray examination of the skull many complicated shadows were thrown on to the plane of the film, and unless standard views were taken, in which the skull bore a definite angle and relation to the film, the task of interpretation was extremely difficult. If, as was *done* in the past, a patient was balanced in the nose-chin position or the post-forehead position, the radiogram might be totally different according to the length of the patient's nose or chin or the recession or bulging of his forehead. He thought some definite line should be taken, such as *one from the outer canthus of the eye to* the external auditory meatus, and this made to bear a certain fixed angle to the film. With regard to the number of radiograms which should be taken in a case, if the number were limited to, say, two antero-posterior and one lateral, many fractures of the skull would be missed. A number of standard views ought to be taken—he himself used as many as seven or eight. He showed on the lantern screen a number of radiographs of the skull, illustrating different positions and types of fracture.

Dr. C. P. SYMONDS said that the general picture which Mr. Trotter had drawn of cerebral contusion had enabled *those of them who attempted to follow* in his *footsteps* to recognize what was, after all, a very clean-cut clinical syndrome. The lawyer, as Mr. Trotter had said, looked always for objective evidence. What the lawyer liked to be able to show was an *x*-ray picture of a fracture of the skull. The lawyer had to be taught, not only that severe cerebral injury did occur without fracture of the skull, but that the symptoms of such cerebral injury were quite well defined. The speaker thought the symptoms of cerebral contusion to be quite easily recognizable by anyone who took the trouble to obtain a careful history. They had for a long time suffered under the ill-used label of "traumatic neurasthenia," and this, he thought, was a conception which had to be taken in hand and clarified. It was just as important to get rid of that designation, which usually concealed all that it was intended to cover, as of the notion that a fracture of the skull was the all-important thing in head injury. The difficulty of diagnosis rested largely upon the absence of physical signs. One had to rely upon a *critical analysis of the patient's* symptoms. The symptoms, as a rule, presented themselves under three headings: headache, giddiness, and minor mental disorder. Unfortunately, the symptoms falling into this third category were the most difficult to evaluate because of the complicating picture of the compensation neurosis which was so often superadded to the organic cerebral symptoms. Therefore the other two, the headache and the giddiness, were perhaps of the greater value. One point that struck him as being of importance about the headache in cerebral contusion—though he found it difficult to understand—was the latent interval that occurred so commonly between the accident and the development of the headache. This latent interval might extend to days, or even to weeks. It was, at any rate, a symptom not likely to be invented by the malingerer who sought to make capital out of his head injury. One feature of the headache was its relation to any posture, such as stooping, which was likely to cause intracranial pressure, and to coughing and straining. The association of a particular kind of headache with a particular kind of giddiness provided extremely good clinical evidence. The giddiness of which these patients complained was, as a rule, quite transient, a momentary sense of loss of equilibrium, which was as a rule even more definitely related to posture than was the headache. The giddiness was felt when the patient raised his head after lacing his boots, or turned his head quickly when crossing the street. These two symptoms together constituted a very characteristic picture of a bruised brain. The greater difficulty was to assess the mental symptoms of which the patient complained; but again a critical analysis would often enable a distinction to be made between the mental

symptoms in these patients and in patients suffering from a neurosis. The neurotic patient might complain of inability to concentrate and of excessive fatigability, but at the end of half an hour's examination it was usually the physician who showed more mental fatigue than the patient. The patient with a true cerebral contusion would show the symptoms that one expected in a mental state which depended upon organic cerebral disease—for example, slowing of thought, defective memory, and true mental fatigue, which could be assessed by objective examination, not simply by the statements of the patient. Referring to recent histological work which showed that, following minor injuries to the brain, very slowly developing changes might take place in the neuroglia, leading to vascular displacement and possibly to vascular congestion, Dr. Symonds considered that this might explain the progressive nature of some of these cases, with delayed onset of symptoms.

Dr. G. VILVANDRÉ advocated as a routine practice the taking of stereoscopic views of the skull. The antero-posterior view and the lateral view had a limited value, and no true knowledge of the skull was obtained without stereoscopy. He felt as a radiologist that fracture of the skull was very liable to distract attention from brain injury. He mentioned one or two cases of depressed fracture which were successfully treated without operation.

Sir JAMES DUNDAS-GRANT said that while he was working at the West End Hospital for Nervous Diseases he had the opportunity of seeing a number of cases of vertigo, with a history of injury to the head. In many of these an injury of the internal ear could be traced and in others this was not discoverable, but in quite a number in which, following Erichsen, he gave small doses of perchloride of mercury, there was a gratifying result. The effect of mercury might be more understandable on the supposition that there was a slow, more or less inflammatory, change in the neuroglia.

Dr. GEORGE RIDDOCH said that while it was true that loss of consciousness as the result of concussion was the usual precursor of contusion and contusion headaches, contusion headaches might follow a head injury in which no loss of consciousness had occurred. Dr. Symonds had raised the difficult problem of the mechanism of the production of headaches after a long waiting period. Sometimes such headaches, which might become severe, lost their paroxysmal character, and took on a more or less continuous intensity. He could not help thinking that external changes of a progressive kind in the meninges might also be present. With regard to treatment, he emphasized the importance of keeping patients in bed longer than the few days usually considered necessary. If more attention were paid to the rest period in the early stages fewer contusion headaches would result. How to deal with the more severe cases was a difficult question. In some the replacement of spinal fluid with air had proved successful in curing headaches of a moderately severe sort. Decompression operations in the region of the contusion, which were practised successfully in the war, had not been so successful, in his experience, in dealing with the more general injuries of civil life. He felt sure that much work had still to be done in this most important branch of medicine, which, therapeutically, and diagnostically also, was more within the province of the physician than of the surgeon.

Mr. WILFRED TROTTER, in replying on the discussion, said that one of the mysteries of cerebral pathology was that a patient might enjoy apparently normal health for perceptible periods after the injury, and then suffer from quite disabling headaches. He could not answer the question which Dr. Symonds had asked with regard to this latent period. He had been gratified to hear of Dr. Vilvandré's two cases of depressed fracture which had been treated without operation. He had himself given up the doctrine in which they were all instructed—that, except in a young infant, an operation should always be done in depressed fracture. The reason usually given why a symptomless depressed fracture should be operated on was the risk of epilepsy developing. But he believed that the risk of epilepsy developing from a simple depressed fracture was no greater than the risk of epilepsy following operation which included the incision of the dura mater.

ANAESTHESIA IN RECTAL SURGERY.

AT a meeting of the Section of Anaesthetics of the Royal Society of Medicine on December 6th, Dr. J. K. HASLER opened a discussion on anaesthesia in rectal surgery.

Dr. Hasler classified operations on the rectum into two groups: those in the abdomen and those in the perineum. The former were not markedly different from any other form of abdominal surgery, except that they were often the first of a two-stage operation, and the first anaesthetic had therefore to leave the patient fit for the second operation. Those in the perineum, apart from operations for dealing with cancer, required a short, deep anaesthesia, if a general anaesthetic was given, and for these chloroform was widely condemned. Local and regional anaesthetics were particularly valuable in rectal surgery, and might be classified into three groups: infiltration; extradural, caudal, and sacral; and intradural, spinal, low spinal, and spinocain. Abdominal operations in this type of case were usually done because of malignant disease in connexion with the rectum, and the chief requirements of the anaesthetic were sufficient relaxation of the parts, sufficient anaesthesia for proper visceral exploration, and sufficient duration of anaesthesia to prevent straining while the surgeon was suturing the abdomen. Infiltration round the rectum would permit such operations as removal of piles to be carried out without pain to the patient, but was usually insufficient for operations on fistulae and fissure. Caudal and sacral blocks were sometimes painful, and there was always a percentage of cases in which these methods failed to produce anaesthesia. The foramina were hard to find, and the time occupied in producing anaesthesia was lengthy. Intradural anaesthesia was valuable, especially in cases of cancer of the rectum; it was best accompanied with either a light general anaesthesia or some form of twilight sleep. If necessary, a second injection of scopolamine could be given during the operation. If the operation was likely to last more than an hour, the intradural injection should be combined with a caudal block anaesthesia and would allow of anaesthesia for one and a half hours. For small rectal operations, a low spinal injection of a light solution of stovaine between the fourth and fifth lumbar vertebrae, given very slowly to the patient in the sitting posture, would often allow of two hours' anaesthesia, and a low spinal injection did not affect the bladder. For fistulae, complete anaesthesia was a disadvantage, as it was difficult to recognize the sphincters when relaxation was complete.

Mr. E. T. C. MILLIGAN, speaking as a surgeon, said that relaxation of the sphincters was unimportant in operations for piles, but important in fistula operations where the extent of the fistula was not known. From the point of view of the patient it was important to abolish apprehension before, pain and apprehension during, and pain after operation. Caudal block was unreliable, varying from perfect anaesthesia to absence of anaesthesia. The operator should be the person to administer local anaesthetics. In some patients good results could be obtained from these, but in others they were useless. Gas and oxygen, with preliminary sedative medication, was best for apprehensive patients. Pain after operation was variable and bore no relation to the anaesthetic used.

Dr. A. L. FLEMMING asked what was the specific gravity of the solution used by the opener. He inquired why novocain was not used *vice* stovaine and why the light instead of the heavy solution was recommended. He also wished to know the advantages of a small amount of a strong solution instead of a larger amount of a weaker solution.

Dr. HOWARD JONES also questioned the use of stovaine. He described fully the physical properties of a 10 per cent. solution of novocain, and explained how such a solution got steadily more dilute as it mixed with more and more of the cerebro-spinal fluid. He also described experiments he had made with a new spinal anaesthetic—percain, which had no relation to novocain or cocaine, but was a derivative of quinoline. The drug, which was not yet being produced commercially, gave excellent anaesthesia up to four hours, even when used in very weak solutions such as 1/20 per cent. in normal saline. He intended publishing his results shortly.

whom he was in daily contact. This was, said Dr. Hart, a formidable task, impossible for the doctor alone, so that organized team work had to be employed and was an essential feature of the child guidance work which was slowly gaining ground in this country. The team of a child guidance clinic consisted essentially of a psychiatrist, a psychologist, and a social worker. The psychiatrist acted as head of the clinic and was responsible for the physical and general examination; the psychologist investigated the mental make-up, its stresses and strains; while the social worker, a highly trained person, became acquainted with the whole environment of the child at home, and carried out such "home treatment" as was necessary. While the idea of team work was often repugnant to the clinician, and while it often displaced the delicate relationship between doctor and patient, yet the work could only be carried out in this way, and the social worker's contribution was most valuable.

Dr. H. C. CAMERON commented first upon the absence of a paediatrician from the scheme described by Dr. Hart, and emphasized that the difficult child was often a problem in pure paediatrics without involving the psychiatric side. He then described the physical aspect of the difficult or nervous child, stressing the etiological significance of the metabolic instability underlying its disordered conduct. He showed how unrest, sleeplessness, and all the other symptoms of the difficult child could lead to a metabolic disturbance, and that this disturbance would accentuate metabolic disorders. It was recognized that nervous children were intolerant of fat, and all their energy was derived from a meagre store of carbohydrate. The nervous child quickly depleted its carbohydrate reserve and developed many symptoms of glycopenia. Irritability, apprehension, and confusional states could develop in this way, and such nervous manifestations had to be attacked through the inactive liver, and the metabolic disturbance put right before psychiatry could have much success. A high sugar diet with low fat and the frequent administration of glucose was of great importance. In conclusion, Dr. Cameron again stressed the importance of the pure paediatric outlook in these cases.

Dr. W. MOODIE gave a description of the methods adopted at a child guidance centre. It had been found that most of the problems of the difficult child had to be dealt with from four aspects—physical, temperamental, intellectual, and environmental. The first two were generally dealt with by the psychiatrist, the third by the psychologist, and the last by the social worker, who had to collect a great deal of information in a painstaking manner. The psychologist not only worked out the intelligence quotient, but also got information about the general make-up of the child. When all the reports were ready a "case conference" was held at which interested parties could be present. The psychiatrist decided upon the treatment, which was then carried out by all the workers as required. The disadvantages of the child guidance clinic were more theoretical than real, said Dr. Moodie, and he believed that the child guidance scheme represented a great advance in the study of child problems.

Dr. EMANUEL MILLER dealt with the difficult child who had no demonstrable disease of organs and no metabolic disorders which could be described as primary. His observations were based upon children of 5 to 16 years seen at the child guidance clinic of the Jewish Health Organization. There seemed to be many cases where psychological disturbances could be related to social and environmental errors, but there was a large group in which only an indirect relationship existed. Dr. Miller said that, with the type of child who was an angel in the home and a devil at school, he found it difficult to believe that such differences in behaviour were "poised upon a carbon atom." The task of the social worker was of great importance, but possibly spectacular success might mask the true nature of the problem, which was not directly due to environmental errors. It was important to be able to recognize the type of child in whose treatment social work would be of value.

Miss FILDES suggested ways in which a lay psychologist could be of help in studying the problems of the difficult child. A great deal of time and investigation was necessary if the environment and internal capacity of the difficult child were to be effectively adjusted, and this was especially true of children of differing intellectual capacities. The lay psychologist could investigate the intellectual as well as the emotional state of the child, and while the intelligence quotient was valuable it was not so important as close observation of how the child performed his tests. The lay psychologist was also of great help in dealing with special problems associated with school life.

The PRESIDENT said that the difficult child was easier to describe than to define, and he pointed out that the conduct of a child was viewed differently according to social rank, so that a "difficult" child of the upper classes might be regarded as "high-spirited" and "plucky" among poorer people. The difficult child was usually not mentally backward, but developed a sort of impish malignancy in conduct. He said that he believed firmly in the importance of environmental factors, though it was difficult to get parents nowadays to be more than mere spectators of official activity.

Dr. T. R. HILL described two groups of children with disorders of conduct arising from disease of the central nervous system. One of these diseases was chronic epidemic encephalitis, where a gross exaggeration of emotions occurred, with lack of control. The optic thalamus appeared to be the area of the brain responsible for such crude behaviour, and a drug, bulbocapnine, was of remarkable benefit to these cases. Similar behaviour disturbances also occurred in non-encephalitic dyspituitarism. He thought more study should be devoted to the thalamic region.

Dr. D. W. WINNICOTT thought that the child's unconscious had to be closely studied over a long period, and this could be done partly by watching the child at play.

Miss CHADWICK agreed that excellent diagnostic work was being done by child guidance clinics, but there was a great lack of information about what happened after diagnosis. She asked if the social worker talked to the parents, and to what extent the psychiatrist talked to the child.

Dr. N. H. M. BURKE described some results of work at a child guidance clinic. In a group of 30 cases home conditions were mostly responsible for the problems of the child, and in only two of these did attempts at readjustment completely fail. Completely successful results were obtained in six cases, and fairly successful in nineteen. Dr. Burke described some of the methods adopted, and emphasized the need for observation of cases in institutions.

Dr. J. R. REES said that, while his experience at the Tavistock Clinic was against the value of child analysis, he thought that all doctors dealing with child guidance work should have the analytic point of view. Talk of readjusting environmental conditions was merely "wild and woolly" unless the psychological implications of the situation were realized.

Dr. M. LOWENFELD said that difficulties seemed to arise when children had to return to certain environmental surroundings after improvement had taken place elsewhere. She thought that the analytic outlook was therefore important, and much information could be obtained about the child's unconscious by watching him at play. She recommended *High Wind in Jamaica*, by Richard Hughes, as a clever study of the child's mind.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS.

THE sixth meeting of the Society of British Neurological Surgeons was held in Oxford, on November 22nd and 23rd, under the presidency of Sir PERCY SARGENT. The first day was occupied with papers, commencing with a discussion on Jacksonian epilepsy, the historical background of which was sketched in by Mr. GEOFFREY JEFFERSON.

The PRESIDENT described two cases of compression of the spinal cord by unusual agents, in the first by a mass of septic granulation tissue. Although the infected material was intradural, and *Staphylococcus aureus* was cultured

Dr. HADFIELD said he had heard of percain, but had no personal knowledge of it, though he had read the literature. It was claimed that by flooding the peritoneum with a very weak solution of the drug, intraperitoneal operations could be carried out painlessly and without after-pain. He wished Dr. Hasler could explain how light solutions travelled down, as he said they did, in his low spinal cases. In his own experience they tended to travel up, as if the patient was in the Trendelenburg position. The average duration of anaesthesia was forty-five minutes, and this could not be lengthened by injecting more stovaine—for example, 1 c.cm. in place of 0.6 to 0.7 c.cm.

Dr. F. T. EVANS disagreed with the suggestion that deep anaesthesia was necessary in cases of piles, fissures, and fistulae. Usually gas and oxygen was sufficient, but a little ether could be added if necessary.

OTO-RHINO-LARYNGOLOGY.

AT a meeting of the Section of Laryngology of the Royal Society of Medicine on December 6th, the president, Dr. DAN MCKENZIE, in opening the proceedings, extended a cordial welcome to Dr. Harris Mosher of U.S.A., the Semon Lecturer.

Sir STCLAIR THOMSON showed the larynx of a man upon whom he had operated in 1909. A portion removed at that date, when the patient was 59, showed it to be squamous-celled carcinoma. He died last winter from heart failure, and there was no recurrence anywhere. The patient had written to say he had carried on his profession as schoolmaster ever since, and smoked a great deal. Sir StClair exhibited also four patients to illustrate some points in subglottic cancer of the larynx, and the condition a varying number of years after operation by the laryngo-fissure route. In the first of these there was no recurrence fourteen years after the operation. In the second there was good mobility of the cords, and there had been freedom from recurrence for nearly nine years. In the third there was absence of recurrence and a good voice six years later. In the fourth case the diseased area was removed *en masse*, and four years later there was a remarkably good voice and freedom from recurrence.

Dr. LOGAN TURNER (Edinburgh) spoke of a paper by the Registrar-General for Scotland on the supposed increase of cancer, in which it was shown that there was a definite increase of the mention of cancer on death certificates: but the suggestion was made that this might be due to a greater correctness of diagnosis, rather than to any material increase in the incidence. Another reason for the increased figure was the greater average longevity of people. The returns showed a real increase of cancer among women, and Dr. Logan Turner thought that in many cases classed as laryngeal the cancer of the larynx was secondary to that in the post-cricoid region.

Mr. ARCHER RYLAND showed a girl, aged 9, who presented a fibrous stricture following the swallowing of some lysol five years ago; though the child was now on ordinary diet and was eating well, she was puny for her age. The PRESIDENT exhibited a woman, aged 61, with enchondroma of the larynx. She had no laryngeal symptoms, and the growth was discovered accidentally; evidently it was growing from the cricoid cartilage.

Mr. L. GRAHAM BROWN showed a male patient, aged 34, who had had an osteoma of the frontal sinus. He had removed the bony growth, with part of the floor of the frontal sinus. The wound was treated by the open method, and in a fortnight it was completely closed. Mr. HERBERT TILLEY gave details of a good method of removal of such growths, which was told him by Sir Harold Stiles—namely, to slit alongside the septal cartilage as far back as possible.

Mr. V. E. NEGUS showed two cases. The first was one of haemorrhage following incision into a quinsy. A good deal of blood was lost. Transfusion was done, and a large pack was sewn in, the two pillars of the fauces being united over it. The pathologist reported that the tonsil removed showed evidence of fibrosis and acute inflammation. Mr. Negus's second communication was a report of spontaneous haemorrhage in a boy, aged 13½, whose tonsils had previously been removed. There was a history of fever, vomiting, rhinitis, and some epistaxis; also swelling of neck glands. A throat swab showed pneumococci only. After the development of quinsy the incision of it led to a large outpouring of blood. The external carotid artery was tied, but the patient a week later woke up suddenly from sleep, had a violent haemorrhage, and died. The necropsy showed a large sloughing inflammatory cavity lying under cover of the angle of the mandible, and the ascending pharyngeal artery appeared to go through the cavity and to have burst. In both lungs there was early pneumonia.

Mr. E. WATSON-WILLIAMS showed an epithelioma of the uvula from a patient aged 80. For a month the patient had had severe pain in the throat on swallowing, also at night. He had arterio-sclerosis and albuminuria. There was seen a papillary growth at the end of the uvula; it was ulcerated in the centre, was hard and tender, though there was no manifest change in mobility. No enlarged glands were to be seen. A month later the growth had encircled the base of the uvula like a collar, and the ulceration had left a conical raw tip. Under novocain he removed it with scissors, with the uvula and a small area of soft palate. Two years later the patient died from arterio-sclerosis, without any recurrence of growth. It appeared to be a growth of low malignancy.

Mr. NORMAN PATTERSON showed two patients with carcinoma of the palate, men aged respectively 54 and 71. The first of them had been diagnosed as lupus, but with that he did not agree. The second and older patient was treated with diathermy eleven years ago, followed by a complete block dissection, including removal of the sterno-mastoid and internal jugular vein on the right side, and though the pathological report was squamous-celled carcinoma the patient still remained well. Sir JAMES DUNDAS-GRANT showed a man, aged 35, with lymphadenoma [illegible]. There was a fleshy infiltration of [illegible]ds, and, somewhat less, of the epi- bacilli in the sputum; Wassermann reaction negative. The patient had had several treatments with *x* rays, and said he felt much better. Mr. D. A. CROW showed two useful devices which he had invented: a radium-needle introducer for use in the hypopharynx, and a chromium-plated head-mirror. Mr. J. C. CLAYTON showed a modification of the Davis gag.

THE DIFFICULT CHILD.

AT a meeting of the Section of Psychiatry of the Royal Society of Medicine, held on December 10th, with the president of the Section, Sir ROBERT ARMSTRONG-JONES, in the chair, Dr. BERNARD HART opened a discussion on the difficult child. Members of the Section for the Study of Disease in Children, and of the Child Guidance Council attended by invitation.

Dr. Bernard Hart pointed out that "the difficult child" was a vague term covering a great range of behaviour anomalies, including serious moral delinquencies and a heterogeneous collection of nervous phenomena. In attempting a definition he said that the difficult child was one who presented obstacles in achieving the aim of nurture and education—namely, adaptation to environment. The difficult child had always been a problem to educationist, parent, and doctor, but ideas on the causation of the condition had considerably changed. At first the behaviour of the difficult child was attributed to an extra dose of original sin, to be treated by discipline. Next came the idea of underlying disease or deficiency of the bodily organs, and following on this the view developed that the nervous or difficult child was suffering from a functional nervous disorder. The most modern view was that the fault lay not in any single system or organ, but that the difficult child showed a faulty reaction as a whole, so that psychological as well as physical and metabolic factors had to be taken into account. The modern view considered the difficult child essentially as a problem in behaviour, and hence it was necessary to know a great deal about the child and his environment, his physical and mental make-up, his life at home and school, and the people with

whom he was in daily contact. This was, said Dr. Hart, a formidable task, impossible for the doctor alone, so that organized team work had to be employed and was an essential feature of the child guidance work which was slowly gaining ground in this country. The team of a child guidance clinic consisted essentially of a psychiatrist, a psychologist, and a social worker. The psychiatrist acted as head of the clinic and was responsible for the physical and general examination; the psychologist investigated the mental make-up, its stresses and strains; while the social worker, a highly trained person, became acquainted with the whole environment of the child at home, and carried out such "home treatment" as was necessary. While the idea of team work was often repugnant to the clinician, and while it often displaced the delicate relationship between doctor and patient, yet the work could only be carried out in this way, and the social worker's contribution was most valuable.

Dr. H. C. CAMERON commented first upon the absence of a paediatrician from the scheme described by Dr. Hart, and emphasized that the difficult child was often a problem in pure paediatrics without involving the psychiatric side. He then described the physical aspect of the difficult or nervous child, stressing the etiological significance of the metabolic instability underlying its disordered conduct. He showed how unrest, sleeplessness, and all the other symptoms of the difficult child could lead to a metabolic disturbance, and that this disturbance would accentuate metabolic disorders. It was recognized that nervous children were intolerant of fat, and all their energy was derived from a meagre store of carbohydrate. The nervous child quickly depleted its carbohydrate reserve and developed many symptoms of glycopenia. Irritability, apprehension, and confusional states could develop in this way, and such nervous manifestations had to be attacked through the inactive liver, and the metabolic disturbance put right before psychiatry could have much success. A high sugar diet with low fat and the frequent administration of glucose was of great importance. In conclusion, Dr. Cameron again stressed the importance of the pure paediatric outlook in these cases.

Dr. W. MOODIE gave a description of the methods adopted at a child guidance centre. It had been found that most of the problems of the difficult child had to be dealt with from four aspects—physical, temperamental, intellectual, and environmental. The first two were generally dealt with by the psychiatrist, the third by the psychologist, and the last by the social worker, who had to collect a great deal of information in a painstaking manner. The psychologist not only worked out the intelligence quotient, but also got information about the general make-up of the child. When all the reports were ready a "case conference" was held at which interested parties could be present. The psychiatrist decided upon the treatment, which was then carried out by all the workers as required. The disadvantages of the child guidance clinic were more theoretical than real, said Dr. Moodie, and he believed that the child guidance scheme represented a great advance in the study of child problems.

Dr. EMANUEL MILLER dealt with the difficult child who had no demonstrable disease of organs and no metabolic disorders which could be described as primary. His observations were based upon children of 5 to 16 years seen at the child guidance clinic of the Jewish Health Organization. There seemed to be many cases where psychological disturbances could be related to social and environmental errors, but there was a large group in which only an indirect relationship existed. Dr. Miller said that, with the type of child who was an angel in the home and a devil at school, he found it difficult to believe that such differences in behaviour were "poised upon a carbon atom." The task of the social worker was of great importance, but possibly spectacular success might mask the true nature of the problem, which was not directly due to environmental errors. It was important to be able to recognize the type of child in whose treatment social work would be of value.

Miss FILDES suggested ways in which a lay psychologist could be of help in studying the problems of the difficult child. A great deal of time and investigation was necessary if the environment and internal capacity of the difficult child were to be effectively adjusted, and this was especially true of children of differing intellectual capacities. The lay psychologist could investigate the intellectual as well as the emotional state of the child, and while the intelligence quotient was valuable it was not so important as close observation of how the child performed his tests. The lay psychologist was also of great help in dealing with special problems associated with school life.

The PRESIDENT said that the difficult child was easier to describe than to define, and he pointed out that the conduct of a child was viewed differently according to social rank, so that a "difficult" child of the upper classes might be regarded as "high-spirited" and "plucky" among poorer people. The difficult child was usually not mentally backward, but developed a sort of impish malignancy in conduct. He said that he believed firmly in the importance of environmental factors, though it was difficult to get parents nowadays to be more than mere spectators of official activity.

Dr. T. R. HILL described two groups of children with disorders of conduct arising from disease of the central nervous system. One of these diseases was chronic epidemic encephalitis, where a gross exaggeration of emotions occurred, with lack of control. The optic thalamus appeared to be the area of the brain responsible for such crude behaviour, and a drug, bulbocapnine, was of remarkable benefit to these cases. Similar behaviour disturbances also occurred in non-encephalitic dyspituitarism. He thought more study should be devoted to the thalamic region.

Dr. D. W. WINNICOTT thought that the child's unconscious had to be closely studied over a long period, and this could be done partly by watching the child at play.

Miss CHADWICK agreed that excellent diagnostic work was being done by child guidance clinics, but there was a great lack of information about what happened after diagnosis. She asked if the social worker talked to the parents, and to what extent the psychiatrist talked to the child.

Dr. N. H. M. BURKE described some results of work at a child guidance clinic. In a group of 30 cases home conditions were mostly responsible for the problems of the child, and in only two of these did attempts at readjustment completely fail. Completely successful results were obtained in six cases, and fairly successful in nineteen. Dr. Burke described some of the methods adopted, and emphasized the need for observation of cases in institutions.

Dr. J. R. REES said that, while his experience at the Tavistock Clinic was against the value of child analysis, he thought that all doctors dealing with child guidance work should have the analytic point of view. Talk of readjusting environmental conditions was merely "wild and woolly" unless the psychological implications of the situation were realized.

Dr. M. LOWENFELD said that difficulties seemed to arise when children had to return to certain environmental surroundings after improvement had taken place elsewhere. She thought that the analytic outlook was therefore important, and much information could be obtained about the child's unconscious by watching him at play. She recommended *High Wind in Jamaica*, by Richard Hughes, as a clever study of the child's mind.

SOCIETY OF BRITISH NEUROLOGICAL SURGEONS.

THE sixth meeting of the Society of British Neurological Surgeons was held in Oxford, on November 22nd and 23rd, under the presidency of Sir PERCY SARGENT. The first day was occupied with papers, commencing with a discussion on Jacksonian epilepsy, the historical background of which was sketched in by Mr. GEOFFREY JEFFERSON.

The PRESIDENT described two cases of compression of the spinal cord by unusual agents, in the first by a mass of septic granulation tissue. Although the infected material was intradural, and *Staphylococcus aureus* was cultured

from it, the patient made a good recovery. She had previously had a severe septic infection of the arm. The second case was a large non-syphilitic aneurysm of the anterior spinal artery in a young woman, the subject of congenital aortic stenosis.

Mr. HUGH CAIRNS demonstrated three cases he had operated upon: a woman with a large frontal cyst with a superficial mural nodule that had been easily removed (radon was subsequently inserted); a woman from whom a tumour of the vermis had been removed by electro-surgery at a second session some months after a sub-occipital decompression had relieved her troubles; the third a boy whose vermis was split at operation, but no tumour found.

Mr. DOTT showed the lantern slides of an arterial angioma of the right hemisphere outlined by sodium iodide injected into the internal carotid artery under local anaesthesia. Good pictures were obtained and the internal carotid artery tied. Deep *x*-ray therapy was being continued in this case.

Mr. JEFFERSON showed ventriculograms of a case in which establishment of the fact that the third ventricle was dilated led to the exposure and removal of the tumour.

In the afternoon Sir FARQUHAR BUZZARD, with Dr. GIBSON and Dr. COLLIER, showed a series of cases in which the diagnosis and management of cerebral and spinal conditions were discussed. The first was a young man with severe occasional headache, with no choking of the optic discs. He complained of flashes of light in the left visual field, whilst the only positive finding was absence of the left abdominal reflexes. Sir Farquhar Buzzard was inclined to consider tumour the most probable explanation, and to place the growth in the right temporal area. The question of ventriculography was discussed in relation to this case. A case of paraplegia, occurring in a young woman with a history dating from an injury to the back, was next reviewed. The most probable diagnosis seemed to be meningitis serosa, and the cerebro-spinal fluid changes in this disease were then debated. Dr. Gibson showed a case in which Jacksonian seizures were occurring in the right side of the mouth and in the right hand. The fact that there was no papilloedema was regarded as no evidence that a large tumour might not be present, but the patient refused operation. The help to be obtained from *x* rays, and the possibility of treating the case by deep *x*-ray therapy, were gone into. The last was that of a man who had suffered a parietal wound and then developed epilepsy. Sir Percy Sargent had plated the bone defect, and the epilepsy ceased for some years. On its reappearance some little time ago Mr. Bevers had put in a second plate, with again an improvement. Sir Farquhar Buzzard showed a case of left-sided acoustic neuroma removed by Sir Percy Sargent some time ago, an unusually good result in a type of case that is often disappointing.

The society's dinner was held in Magdalen College on the evening of November 22nd, and the meeting was concluded on November 23rd by a demonstration in Sir Charles Sherrington's laboratories. A fascinating series of addresses and illustrations was given by Dr. J. F. FULTON, Dr. LIDDELL, Miss COOPER, Dr. DENNY-BROWN, and Dr. ECCLES, with comments from Sir CHARLES SHERRINGTON. The demonstrations were most stimulating, and should be fruitful in further clinical observation on cerebellar and spinal lesions in particular. Mr. CAIRNS and Dr. FULTON described the effects of various doses of radon on the normal spinal cord, with a view to arriving at a safe dose for human beings with tumours. Mr. DOTT described the uses of electro-surgery in neurological work, the action of the current, and his experiences with it. He commented on the fact that the line of section was so clean and undamaged that it might recommend itself to experimental work as well. The various machines available and possible improvements were discussed by the members.

THE president and council of the Harveian Society of London have awarded the biennial Buckston Browne prize (£100 and medal) to Dr. C. Bruce Perry for his essay on chronic streptococcal illnesses; proxime accessit, Dr. R. Cove-Smith.

Reviews.

THERAPEUTICS OF NEPHRITIS BASED ON ETIOLOGY.

REPEATED investigation of the exciting causes of the various forms of nephritis is still profitable and necessary, and V. KOLLERT, E. SUCHANEK (a throat and nose surgeon), and S. SINGER (a radiologist), have placed on record, in a monograph[1] of 158 pages, their observations at the Second Medical Clinic in Vienna between 1918 and 1928. In their work they follow broadly the well-known Volhard-Fahr classification of renal disease. Part I of the monograph deals with the role of microbic infection in glomerulonephritis; Part II with methods of investigating the infections by general clinical means and by methods specially appertaining to the otologist, laryngologist, and radiologist; Part III with the treatment of renal disease based on the observations made.

The authors give an interesting list of 80 cases of acute nephritis, which can be separated into three groups—55 in which the influence of a primary infection is without doubt, 21 in which an initial infection can be suspected but is not so certain, and 4 in which there is not any evidence to suggest the cause of the renal damage. Their list of acute infections brings out nothing new, including as it does acute tonsillitis, ear infections, bronchitis, pneumonia, erysipelas, scarlet fever, measles, influenza, and, lastly, the unknown element involved in severe chill due to exposure. The relation of these acute infections to the actual onset of nephritis is very carefully considered, and Kollert finally suggests the following rule, which sets forth a point of view that is not commonly held but is very interesting. *In his opinion the sequence of events is* frequently as follows. First, there occurs in the body a fairly severe microbic infection of short duration, often without any localizing signs whatever, and thereafter follows a pause of several days during which the patient feels well. Then suddenly the first renal symptoms appear, while at the same time, or even slightly earlier, careful examination brings out signs of a microbic infection, generally milder, and now with definite localizing signs. Further, the view is put forward that glomerulonephritis, even in its advanced stages, must not be regarded as the sequel of a microbic infection long since terminated, but as due to the continuing influence of an active microbic cause now strictly localized somewhere in the body, removal of which may materially assist cure. The methods by which the existence and site of the localized infection can be recognized are discussed, including general clinical observations, such as leucocyte counts and records of temperature, and special methods used by the laryngologist and radiologist.

There is nothing perhaps very new in the work described, but it is well done, and the book gives a record of evidence that can be quoted elsewhere.

SURGERY OF THE JAW-JOINTS.

IN his book on the temporo-maxillary joint,[2] Dr. DUFOURMENTEL, professor of maxillo-facial surgery at the Dental School of France, covers ground which is a kind of no-man's-land of surgery, for, as he remarks in his introduction, the surgeon is apt to leave it to the dentist, and the dentist considers that it belongs to the domain of surgery, though troubles of this joint are often made manifest by disarrangement of the teeth. The subject has attracted increased attention since the war, when nearly every sort and extent of injury that is not immediately fatal, to which the human frame can be subjected, came under treatment—often in great numbers.

The temporo-maxillary joint can be considered as one of a pair of twins, neither of which can be damaged without impairing the function of the other. In this respect it is

[1] *Grundlagen der ätiologischen Behandlung der Nierentzundungen.* Von Privatdozent Dr. Viktor Kollert. Mit Beiträgen von Dr. E. Suchanek und Dr. S. Singer. Leipzig und Wien: F. Deuticke. 1929. (6½ × 9½, pp. vi + 158; 3 figures. M.9.)

[2] *Chirurgie de l'Articulation Temporo-Maxillaire.* Par L. Dufourmentel. Préface du Professeur Pierre Sebileau. Paris: Masson et Cie. 1929. (6½ × 9½, pp. x + 228, 69 figures. 40 fr.)

unique in the human body, unless the intervertebral articulations are considered analogous. Professor PIERRE SEBILEAU, who has written the preface, points out the difficulties of approach to the actual joint, the importance of structures—such as the facial nerve—close to it, and the limited field of operation when the joint is reached. Moreover, it is only after considerable experience that the information afforded by radiograms can be properly appreciated, as the many reproductions of them in this book prove.

Dr. Dufourmentel opens his work with an account of arthritis of all kinds, acute and chronic, and goes on to consider trismus, deviations of the mandible brought about by joint troubles, prognathism or underhanging jaw, luxations, and the ankyloses which follow on arthritis or injury; and in relation to each of these conditions he discusses the operations necessary and practicable for their relief. The last chapter treats of fractures involving the joint and their results and treatment.

Each chapter has its own bibliography of references, in which few British names will be found. Except for recent work at Sidcup, the surgery of this region has perhaps not received in this country all the attention it deserves; and stomatology, to which Dr. Dufourmentel assigns his subject, has seemed to most of us to be too minute a division to be accepted as a specialty apart from dentistry. In so far then as the subject may have been neglected in Britain, interest in it should be stimulated by this book, and all who have difficult cases involving the temporo-maxillary joints would do well to consult it.

ENEMIES OF MEDICAL SCIENCE.

PROFESSOR H. W. HAGGARD of Yale University, in his volume entitled *Devils, Drugs, and Doctors*,[3] gives a popular account of the development of medicine and of the manner in which medical science gradually extricated itself from mediaeval superstition and quackery. The author has not attempted to write a formal history of medicine, but has been content to describe the way in which some of the chief advances occurred. The book is written in an easy and readable style, and is profusely illustrated; hence it should possess a considerable popular appeal. One of the most interesting points brought out is the intensity and variety of opposition encountered by every attempt to advance medicine. Most reforms have been vigorously opposed by a die-hard section of the profession. Such resistance is, however, almost inevitable in any profession, because it is never pleasant to admit that the teaching and practice of a lifetime have been erroneous, and there will always be a powerful group who refuse to make such an admission until the evidence has become overwhelming. Professor Haggard does not mention the opposition to Harvey's discoveries, but this is scarcely necessary, because it is never forgotten by anyone who disagrees with the medical profession, and the more blatant the fraud or delusion the more certain is it that the shade of Harvey will be invoked. The tragic story of Semmelweis is, however, told fully, and reference also is made to the opposition encountered by Lister.

Of greater interest than this internal resistance is the mass of more or less gratuitous external hostility that has hindered the advance of medicine. The history of the development of obstetrics illustrates this point. In the classical period midwifery was practised by physicians who used podalic version, and employed abortion when the life of the mother was in danger. Mediaeval prudery abolished the male midwife, while abortion for any reason was banned. As the author says: "No greater crimes were ever committed in the name of civilization, religious faith, and smug ignorance, than the sacrifice of the lives of countless mothers and children in the first fifteen centuries after Christ among civilized mankind." The opposition on religious grounds to Sir James Young Simpson's introduction of anaesthesia in obstetrics is a comparatively recent memory. Professor Haggard has, however, rescued many gems of pulpit rhetoric, and also gives an amusing account of the dexterity and skill with which Simpson fought his adversaries text by text through the Bible.

Popular prejudice has been a constant limiting factor in the development of preventive medicine. The opposition to vaccination is too well known to need description, but it is interesting to learn that the original campaign was supported by the argument "Small-pox is a visitation from God and originates in man, but cow-pox is produced by presumptuous, impious men. The former Heaven ordained, the latter is perhaps a daring and profane violation of our holy order." The history of venereal disease furnishes another example of how preventive medicine was handicapped for centuries by a public opinion that was uncertain whether these diseases ought not to be regarded as a valuable aid in preserving a standard of sexual morality. The conflicts mentioned above are well known, but the author stresses another and less familiar fact—namely, that "faith healing" has been a constant check to the development of scientific medicine. After tracing its appearance through the ages in such diverse forms as the "royal touch" for king's evil, the exorcism of devils, the cures by relics and at healing shrines, he gives an interesting account of the development of faith healing in the United States in the nineteenth century. Andrew Jackson of Poughkeepsie, Francis Schlatter, J. A. Dowie, and Phineas Quimby of Maine all had considerable local success as faith healers, and the last-mentioned had as patient and pupil Mrs. Mary Baker Eddy, who wrote *Science and Health* in 1875 and founded Christian Science. As the author says, "Faith healing, both past and present, has assumed innumerable forms, and there will probably be many more in the future as old methods are revived, renamed, and adjusted to the latest scientific fad." Moreover, there is considerable weight in his suggestion that the vogue of faith cures "conducted by religious sects or by medical charlatans is an expression of the unsympathetic attitude of the medical profession toward minor and imaginary ailments." His general conclusions are summarized in a paragraph that occurs in the last chapter:

> "It is not surprising that rational medicine has opponents. Man's inherent nature is such that he has an almost intuitive belief in primitive medicine, and this intuition can be reformed only by education and reason. Many people with a merely literary or religious education have never learned to think logically in matters of health. They do not understand the principles of science, and are therefore controlled by sentiment and by opinions which are held tenaciously because they are matters of faith. In the same way savages, when brought into contact with civilization, may adopt some of its conveniences and many of its vices, but they do not adopt its religion or its medicine. They wear conventional clothing, eat canned food, and ride in automobiles, but they remain savages at heart."

PRACTICAL DIETETICS.

To judge from current literature, the organized application of medical knowledge in the United States is far in advance of that in this country. Professor MARY S. ROSE's *Laboratory Handbook for Dietetics*,[4] the third edition of which has just appeared, is designed for the instruction in dietetics of large classes of students who are destined, presumably, to apply their knowledge, not merely to the preparation of food for the sick, but to the feeding of institutions, schools, and their own (or other people's) families. Nobody will deny the need for the application of scientific principles to the feeding of large groups of men and women, or of children. The better those responsible for the feeding of schools, or of troops—to name the first examples that come to the mind—understand the principles of dietetics, the more successfully and economically will the work be done. Given common sense and adaptability, everything is to be gained, nothing lost, by a sound education in dietetics. Many of us remember the gruesome ministrations of the company cook, usually an individual who gravitated to the position by a process of elimination, having been a proved failure in every other capacity. The recollection will certainly not prejudice us against the employment of persons properly trained for their duties. More doubts may perhaps be entertained as

[3] *Devils, Drugs, and Doctors.* By Howard W. Haggard, M.D. London: W. Heinemann (Medical Books) Ltd. 1929. (6 × 9¼, pp. xxii + 405; illustrated. 21s. net.)

[4] *A Laboratory Handbook for Dietetics.* By Mary Swartz Rose, Ph.D. Third edition. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1929. (Demy 8vo, pp. xiv + 269. 12s. 6d. net.)

to the advisability of treating family cooking in a too scientific manner. In spite of the prevalence of preserved foods, rational human beings may still be trusted to choose their own diet, from the abundant variety offered by modern civilized markets, without grave risk of error. Admittedly, juvenile feeding needs skilled supervision, but otherwise, except where great poverty seriously limits choice, little direction is needed.

Professor Rose's book consists chiefly of elaborate tables showing caloric value, composition, and price of a very large number of foodstuffs. The tables are arranged to give the maximum of convenience, and the minimum risk of error. In addition, there are height and weight tables, and the Du Bois chart for reading off surface area from data of height and weight. The tables are prefaced by a short introduction, explaining their use and the main dietetic principles which justify them. On the whole this part of the book is clear and concise. The remarks on the association between copper and iron (p. 26) are, however, quite unjustifiable, in the present state of our knowledge of this question. On the following page is a statement that might easily be interpreted in the sense that the body's requirements for sodium and potassium are quantitatively on a par with those for fluorine, manganese, and copper. The remark that "iodine is a very active element and too much may be as deleterious as too little, though not in the same way" (p. 27), seems, to say the least, to lack completeness.

SURGICAL ESSAYS.

SURGICAL reflections,[5] by Dr. ERWIN LIEK of Dantzig, is a collection of miscellaneous essays on surgical subjects reprinted for the most part from recent issues of German surgical journals. Generally speaking, the series is rather dull and pessimistic in tone, and the weaknesses and limitations of the art of surgery are stressed throughout. In somewhat sententious phrascology the author expounds his main theme: that firmer foundations must be laid in human physiology before the superstructure of operative surgery can be extended; and that in the meantime it would be well for each individual surgeon to examine critically his own fundamental knowledge and contribute a solid stone or two to the projected new temple of the art. Ten independent essays are presented, and by far the largest and most readable is the first, which is devoted to a study of the diagnostic and therapeutic pitfalls in the right iliac fossa. An exhaustive survey is made of the conditions which mimic acute appendicitis. This essay is supplemented by another, which deals similarly with chronic appendicular and pseudo-appendicular syndromes. Topics touched upon in succeeding essays are the surgical handling of Graves's disease, the question of gastroptosis, and the surgery of the sympathetic system. There is also a brilliant little essay, recalling in substance and style Moynihan's critical surveys, entitled "Disappointments after biliary operations." This essay is much more than a mere enumeration of the mishaps and failures with which everyone is familiar, but is a plea for a thorough overhaul of the physiology of the biliary tract. Anyone contemplating special research and able to read technical German with ease would do well to consult the appropriate essay in this series.

NOTES ON BOOKS.

THE second edition of *The Nutrition of Healthy and Sick Infants and Children*,[6] by Professor E. NOBEL, C. PIRQUET, and R. WAGNER, has already been reviewed in these columns on May 19th, 1928 (p. 851). The authorized translation by Dr. BENJAMIN M. GASUL has been published, and a much wider public will now be able to study the Pirquet system of nutrition and its clinical applications. The translator seems to have performed his task adequately, and he has wisely retained all the charts and diagrams of the original, despite the German words which appear in them. The schematic representation of Pirquet's system was a valuable feature of the original volume, and, with the help of the short glossary provided, readers ought to be able to follow the meaning of these diagrams. Even for those who do not accept the Pirquet system the book still contains much valuable material on nutritional disorders in early life and their management.

The Prevention of Disease in the Individual[7] is the third edition of Dr. KENELM WINSLOW'S *The Prevention of Disease*, which first appeared in 1916, the insertion of the last three words having rightly been made to distinguish it from works dealing with the prevention of disease in the population as a whole. It has had a large sale, and is now enlarged, and costs 5s. more than in 1916. This is a guide on personal hygiene for lay readers; it is clearly written, generally speaking on sensible lines, though all would not agree with the condemnation of tobacco, or the dictum, "If we are smokers, we must confess ourselves fools to our sons in order that they may improve upon their fathers."

In the course of twenty chapters on clinical opotherapy[8] Dr. SCHEFFLER deals in this connexion with old age and premature senility, cancer, high blood pressure and arteriosclerosis, tuberculosis, anaemia and leukaemia, rheumatism, obesity, cardiac, pulmonary, and gastro-intestinal disorders. The net is thus somewhat widely and enthusiastically spread, and there is a good deal that is speculative rather than established. Probably few would adopt, with any hope of success, the advice that in lymphoid leukaemia treatment with splenic and liver substance should always be tried. On the other hand, the author is on sure ground when describing the treatment of diabetes by insulin.

Dr. H. SOMERVILLE, in *Madness in Shakespearian Tragedy*,[9] presents a very well-balanced account of the more abnormal characters in Shakespeare's tragedies. He does not, however, give us much insight into these conditions when looked at from a Freudian or Jungian viewpoint. He deals in succession with Hamlet, Macbeth, Lady Macbeth, Othello, Lear, Ophelia, Goneril, Brutus, Timon, and Constance. This is an interesting and readable book, which most readers will be content to read without unduly criticizing.

In his monograph on the action of light and of antirachitic substances in living organisms,[10] Dr. CURT FALKENHEIM describes a series of experiments made to determine the mode of formation of vitamin D in the animal body. The author found that if the skin of irradiated rats was transplanted into rachitic rats the latter were healed. He showed also that the liver of irradiated rats possessed an antirachitic action. Observations on cows showed that the milk of irradiated cows had a more powerful antirachitic action than the milk of cows either stall-fed or pasture-fed. Irradiated milk, however, had twice as strong an antirachitic action as the milk of irradiated cows.

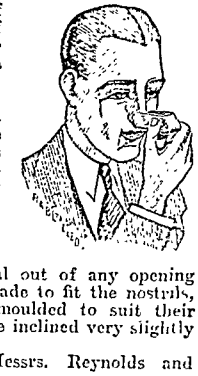
PREPARATIONS AND APPLIANCES.

AN IMPROVED NASAL DOUCHE.

MR. ERNEST E. MADDOX, F.R.C.S.Ed. (consulting ophthalmic surgeon, Royal Victoria and West Hants Hospital, Bournemouth), writes: The douche illustrated, which I devised for ophthalmic practice and which is well adapted to clear the lower opening of the lacrymal duct, may perhaps be of service in general practice also, since it produces a negative instead of a positive pressure in the nasal cavities. With an ordinary nasal douche there is, as we know, a "head of water" above the nose which produces a positive pressure in its passages, and may thus force small septic mucous emboli into the Eustachian canal or into the opening of some nasal sinus. With the improved device, however, the lotion is at a lower level than the nose; since it is drawn up by aspiration the pressure is negative, and would tend rather to draw material out of any opening than to propel anything into it. It is made to fit the nostrils, with *soft metal*, which can be easily moulded to suit their requirement. The patient's head should be inclined very slightly forward, as in the figure.



The douche is manufactured by Messrs. Reynolds and Branson, Leeds.

British Medical Journal.

SATURDAY, DECEMBER 21ST, 1929.

TRAINING OF THE UROLOGIST.

THE education of the medical student of to-day differs as much from that of his forerunner of a century ago as the training of a modern able-bodied seaman does from that of a sailor in the time of Nelson. Methods of teaching surgery which were sufficient in the pre-Listerian epoch would fail utterly to make a modern surgeon, and it is more than likely that a training considered satisfactory to-day will be scrapped as insufficient for the needs of to-morrow. In every country it is probably best that the system of medical education should evolve, as evolve it must, in accordance with its own tradition and the special needs of the people it has to serve. Science and scholarship, indeed, are international, but each nation must cultivate them in its own way, not necessarily—measured by any absolute standard—a better way than that adopted by other nations, but one expressing most nearly its own genius and temperament. The practical application of this principle does not involve a self-imposed cultural isolation; in every field of learning the workers are bound to be influenced by movements and methods outside their own country, and gradually to adapt what they deem to be good in them to their own needs. In the field of medical education three factors have been mainly responsible for determining the evolution of method: the growth of knowledge; the tendency of related facts—whether about a region or a system or a technique—when they have reached a certain saturation, to crystallize out into new specialties; and the increasing number and efficiency of the lines of intercommunication throughout the civilized world.

While science grows with endless profusion, the capacity of the individual man to absorb and make use of its discoveries remains the same. No one, however great his mental capacity and his industry, can make himself master of the whole range of medical knowledge. He may hope to establish a general acquaintance with its basic principles; he may, if he wishes, further devote himself to the task of becoming expert in one of its branches. Whether we like it or not, this tendency to specialization is so far increasing that to-day it has become one of the most significant facts, not only about medical practice, but about medical education. The process, indeed, of so subdividing medicine and medical education has proceeded further in the United States of America than in England; urology, for example, which only now is beginning to establish itself as a specialty in this country, has in America long been recognized as a special branch of practice. Not only has it there its experts and its associations, its journals and its professorial chairs, but it has established its place as a definite subject for study in the curriculum of the medical student and in the post-graduate courses of the qualified practitioner. There can be no doubt that the result, whatever it may have been for the student or the graduate, has been highly favourable to the development of urology itself. The urological school of America has achieved a high reputation throughout the whole world; its leaders and their work are quoted in every textbook; and the facilities for research that have resulted from the gathering together of urological cases and urological data have been the world's as well as America's gain.

The tendency in America to focus interest on special subjects has created a demand for greater facilities for their study. In the *Journal of the American Medical Association* for October 26th (p. 1329), Dr. Joseph McCarthy, who during the last quarter of a century has been continuously engaged in teaching urology to undergraduate and graduate students, and may therefore be regarded as an authority, shows how this demand has been met in the field of his own specialty. The American post-graduate course in urology lasts six months, the membership of classes being limited to ten. The syllabus is comprehensive, and includes lectures and demonstrations, not only in urology, but in related subjects—for example, in proctology, embryology, biochemistry, ophthalmology, and radiography. The teaching is made as practical as possible by means of classes in operative surgery and by bedside demonstrations, followed by discussions on possible errors in diagnosis and treatment. At the end of the six months graduate students who have shown special merit are eligible for the post of intern in the urological department of the hospital at which they took their course. This post, which may be held for two years, provides the practitioner with unrivalled opportunities for acquiring expert knowledge and carrying out research in urological subjects. The scheme outlined by Dr. McCarthy provides also that a promising student who cannot afford the fees may pay them later out of the proceeds of his practice.

In America the immense sums expended on medical education have made possible the adoption of methods which may not be available to smaller and less wealthy nations. It is obvious, however, that if, as appears to be inevitable, medicine is to become more and more differentiated into specialties, better opportunities will have to be provided for their post-graduate study. Our own special hospitals would do well to consider carefully how this change may best be brought about. The English school of urology is young, but among its members it numbers urologists with a world-wide reputation. Closer collaboration between the hospitals devoted to urology and a better system for the post-graduate instruction of practitioners who wish to perfect themselves in its practice would enable this school to take its proper place among the more highly organized urological schools of Europe and America.

THE MENTAL TREATMENT BILL.

THE Mental Treatment Bill, the main provisions of which we discussed in some detail last week, has emerged safely, indeed in a somewhat improved form, from the committee stage in the House of Lords As regards the "voluntary boarder," or, as we (following Lord Dawson) should prefer to call him, the voluntary patient, discussion centred on the proposal to extend treatment on the voluntary basis to adolescents on the sole application of parent or guardian, unsupported by reference to the desires of the patient himself. If full use is to be made of the extended facilities for treatment to be provided under the first part of the bill, it is essential to safeguard the purely voluntary status of the patients to whom they apply, and the original proposal to classify a person of 18, even when unmarried, as a voluntary patient on the strength of an application by any other person was clearly open to grave exception. The requirement of a medical recommendation in connexion with such cases, inserted on the motion of Lord Danesfort, is therefore to be

welcomed, and we may hope that during the report stage the reconsideration of the clause promised by Lord Russell will have resulted in adoption of the proposal to reduce the maximum age of the young person to whom such procedure is applicable without the formal consent of the patient to 16 (as proposed by Lord Cranbrook), and in elimination of the existing exception in favour of married patients. On this matter the special Committee of the British Medical Association on Lunacy and Mental Disorder favours the more drastic reduction of the age limit to the elementary school-leaving age as established at any given date. It may also be found possible to include among the places to be made available for treatment of voluntary patients other establishments, notably training homes, which have proved their value in the treatment of this type of mental disorder but are not at present specified in the bill.

That the proposals for temporary treatment without certification, which are the chief new contribution of the bill to the progress of mental therapy, should meet with determined opposition was perhaps inevitable in view of the Government's courageous departure from the recommendations of the Royal Commission. Decision between the two views—not so much on the merits of the case (for the Royal Commission itself recognized the ultimate objective as the assimilation of the treatment of mental illness to that of physical illness, to a point at which the participation of the magistrate might safely be eliminated), but on the progress already made by public opinion towards a rational appreciation of the requirements of mental treatment—has been postponed until the report stage, in consequence of Lord Brentford's withdrawal of his proposal to substitute the authority of a magistrate for the second medical recommendation required under Clause 5. It is difficult to forecast the result of the promised conference between Lord Russell and Lord Brentford on this matter, for the only practicable compromise between the points of view expressed in the latter's amendment, on the one hand, and in Clause 5 of the bill on the other, would seem to be that which is embodied in the provisional treatment procedure recommended by the Royal Commission—and this has been definitely rejected as ineffective by the promotors of the bill, and, we may add, by responsible medical opinion. For the rest, the adoption of Lord Sandhurst's amendment providing for extensions of the original six months' temporary treatment of non-volitional patients in suitable cases is a definite improvement on the original proposal. The general discussion of this clause will also be of use as serving to define, for the instruction of the public, the exact class of patient to which these provisions are applicable. The definition falls short, perhaps, of what it might usefully have included, and we may hope for the express inclusion, at some later stage in the bill's progress, of persons who do not signify unwillingness for treatment, as well as of persons who are actually for the time being incapable of volition.

So far, then, the bill as amended by the Lords in committee is definitely an improvement on the bill as originally introduced, the full text of which will be found in our *Supplement* of December 7th. It is the more unfortunate that no steps have yet been taken to strengthen it in what, from the point of view of the medical profession, is its weakest part. Lord Sandhurst's proposed amendment of Clause 16 of the bill offered an equitable and, in our opinion, effective measure of protection to persons required to carry out duties under the Lunacy Acts. The absence of adequate protection imposes on the medical practitioner in particular a burden which was recognized by the Royal Commission. The recommendations of the Commission, in this case embodied in the bill by the Government without modification, were recognized by more than one speaker in the course of the debate on the second reading as inadequate, and Lord Sandhurst's amendment, while differing from the proposals put forward by the British Medical Association, and in some respects falling far short of those proposals, seemed to offer a sound and statesmanlike method of strengthening the existing provision. It is therefore with profound disappointment that we find that this amendment disappeared from the order paper of the House of Lords without so much as the tribute of a discussion in committee. It would seem that some other advocate and some other means must be sought for keeping before the legislature and the public the claim of the medical profession for adequate protection. It is surely not too much to ask that those who in fact bear the main burden of the national provision for mental treatment, and whose efforts must determine its success, should be satisfied that they enjoy all reasonable protection in the course of their anxious and difficult work.

THE THANK-OFFERING FUND.

THE Thank-offering Fund for the King's Recovery, for which an appeal was launched on April 29th, immediately after the publication of the King's message to his people, has now been closed, and in a letter to the press, on December 10th, Lord Donoughmore, treasurer of the Fund, announced that the amount collected had reached the total of £689,597. It may be recalled that on April 16th the Chancellor of the Exchequer stated that the Government would contribute out of public money towards the purchase of radium, on a basis of £1 for every £1 otherwise subscribed, up to a limit of £100,000, and a public appeal for a National Radium Fund of £150,000 (making £250,000 in all) was set on foot by the leaders of the medical profession in association with laymen prominently associated with the work of hospitals and cancer research. This appeal, conjointly with a special appeal by King Edward's Hospital Fund in aid of the hospitals in the metropolitan area, was intended to serve as a thank-offering for the King's recovery, and, with Lord Donoughmore as treasurer, the two branches of the appeal were administered in the closest co-operation. So swift and generous was the public response that by May 4th the National Radium Fund had been fully subscribed, and the hospital section, which for its nucleus had the gift of 100,000 guineas offered by "Audax," an anonymous donor, was then extended to include donations for hospitals outside the metropolitan area. After Thanksgiving Day on July 7th, when it was arranged that offerings from congregations might be ear-marked for individual hospitals, no further general effort was made to solicit contributions, but the flow of spontaneous gifts has continued throughout the whole time that the Thank-offering Fund has been open. Out of the £187,000 subscribed to the National Radium Fund a first instalment of £100,000 has been handed over to the National Radium Trustees, to enable them to claim the Government grant of the same amount; a further £50,000 is being held for the trustees, and the balance of £37,000 will be placed at the disposal of the King's Fund for the purchase of radium to be loaned to hospitals in London, subject to the same general conditions as those governing the allocation of the radium bought with the gift of Sir Otto Beit. The 100,000 guineas given by "Audax" will, in accordance with the donor's wishes, be invested and the income used to increase the annual distribution of the King's Fund, which benefits more than 140 hospitals in the London area.

The rest of the money available for the King's Fund will be allocated on the ordinary distribution list of 1929, to promote schemes of extension or improvement at hospitals, or to reduce deficits on schemes of extension or improvement which have recently been carried out. Lord Donoughmore, in his letter announcing the closing of the Fund, expresses the obligation of all concerned to the *Times*, which succeeded in raising the sum required for the National Radium Fund, and has throughout placed its resources at the disposal of the Thank-offering Fund as a whole.

POST-OPERATIVE TETANUS.

A FURTHER report to the Scottish Board of Health has now been made by Dr. T. J. Mackie, Irvine professor of bacteriology in the University of Edinburgh, with reference to post-operative tetanus, as a sequel to his investigation of an outbreak of this infection in an institution; details of his first report appeared in our columns on June 9th, 1928 (p. 987). Professor Mackie, in association with Dr. D. G. S. McLachlan, lecturer in bacteriology at Edinburgh University, and Miss E. J. M. Anderson, has now brought to light certain factors which appear to promote the development of the tetanus bacillus in the tissues. The experiments undertaken illustrate anew the extreme danger of using in certain abdominal and gynaecological operations surgical catgut which has not been sterilized by a method capable of eliminating sporing intestinal bacteria. In the previous report emphasis was laid on the value of iodine in such sterilization, and the relative uselessness of other agents, such as mercury biniodide and heat. The later experiments indicate that the presence of *B. welchii* in a tetanus infection renders this much more grave. Again, it has long been known that the injection into an animal of sterile soil, together with spores of the tetanus bacillus, considerably facilitates the development of a resulting infection. The three investigators have obtained evidence that this effect is not due to any chemical constituents in the soil. The mechanism is, they believe, that the leucocytes ingest the particles of soil, and are thus prevented from ingesting the spores. It was noticed, however, that the injection of other substances, such as Indian ink, which might similarly be expected to "block" the phagocytes, did not do so. Sterile catgut strands by themselves did not promote appreciably the growth of *B. tetani*, but when strands containing these spores in their substance were implanted in the tissues a nidus for germination became available and the development of vegetative forms was assisted; the organisms acquire in this way an anaerobic environment and mechanical protection from phagocytes. Furthermore, the adjuvant influence of *B. welchii* was found to be paralleled in the case of other organisms, including *B. oedematiens*, *Staphylococcus aureus*, and to some extent *B. coli*, but no such predisposing influence was traced in the case of *B. tertius*, *B. sporogenes*, the enterococcus, an organism of the *B. subtilis* group, and *V. septique*. Cold, however, was found to enhance the growth of tetanus in guinea-pigs to a very marked degree, and it is suggested that this may well prove to be a factor of considerable importance; carefully controlled experiments are, however, required before any definite statement can be made. There can be no doubt that a definite and valuable advance has been made; light has been thrown on the whole problem of tetanus infection in general, and of post-operative tetanus in particular. The value of the iodine sterilization of catgut was confirmed in the later experiments. Dr. J. Parlane Kinloch, Chief Medical Officer to the Scottish Department of Health, remarks in a prefatory note to this second report that Professor Mackie and his collaborators, by devising effective standard methods applicable to the sterilization of catgut, have made it practicable to schedule such catgut under the Therapeutic Substances Act, with the result that a small, but tragic, group of post-operative deaths will in future be prevented.

CONTEMPORARY RECOGNITION OF JENNER.

IN the *Canadian Journal of Medicine and Surgery* recently (October, 1929, p. 103) the Right Hon. William Renwick Riddell, Justice of Appeal, Ontario, contributes a short article on the influence of Edward Jenner with foreign potentates. The incident of Jenner's successful mediation with the Emperor Napoleon on behalf of one or more of the *détenus* after the breach of the Peace of Amiens is well known. The incident which Mr. Justice Riddell describes—namely, Jenner's intervention on behalf of the "Canadian pirate"—is less well known. Perhaps the line of demarcation between piracy and filibustering cannot be strictly drawn, but we should be inclined to acquit Jeremiah Powell, the subject of this sketch, of the more sordid crime, and to consider him as a political offender only. Jeremiah was the fourth son of Mr. Justice Powell of Montreal, a Boston loyalist, who, like so many others, had to migrate to Canada after the establishment of the independence of the United States. When only 20 years of age Jeremiah went to Haiti, then under the rule of the negro "Emperor" Dessalines, who had succeeded in driving out the French after the deposition of Toussaint l'Ouverture. His revolutionary ardour led him to join in an attempt to free Venezuela from Spanish rule, and this adventure ended for him in a sentence of ten years' imprisonment at Omoa—a virtual slavery. The King of Spain in 1803 had sent an expedition to his American possessions to introduce and spread the practice of vaccination, and had a high regard for Jenner, whose intercession for young Powell was quickly successful. Jenner wrote not only to the King, but also to Godoy, the powerful, if infamous "Prince of the Peace," and no doubt the message to the latter was the more effective. Mr. Justice Riddell remarks on the contrast between the estimation in which Jenner was held abroad and the treatment he received in England, but we think that too much stress may be laid on the contrast. It is, however, an undoubted fact, as Mr. Justice Riddell says, that the spread of successful vaccination in Britain was largely due to the efforts of non-medical persons such as the Earl of Egremont. The aristocracy in more countries than one have too often been prone to patronize quackery, but on this occasion, though some of their efforts were frustrated, they were on the right side. For instance, in 1800 the Duke of York, then Commander-in-Chief, asked Jenner to vaccinate the 85th Regiment; but unfortunately it was found that the whole regiment, including the men's wives and children, were infected with scabies, and until this should be cured Jenner wisely declined to vaccinate. The disappointing and contradictory results which were obtained at the London Small-pox Hospital are, in view of present-day knowledge, not surprising. That vaccination should have been attempted in such a place seems almost incredible. As we might expect, patients were often inoculated with small-pox as well as or instead of cow-pox, and in any case a susceptible person introduced into a ward full of small-pox cases was likely to catch that disease even before he was vaccinated. There were also small-minded persons who were jealous of Jenner, and only too ready to seize upon any means of attacking him and his procedures. But, after all, these people were not very important. The real leaders of the profession and the men of science quickly did him honour. He won the approbation and support of men like Sir Humphry Davy, Matthew Baillie, Lettsom, and Abernethy. Lettsom, indeed, eulogized Jenner and his discovery before the Medical Society of London, and also defended him

triumphantly when he was decried on other occasions. But the most striking evidence of the honour in which Jenner was ultimately held is to be found in the votes of the House of Commons of sums of £10,000 and £20,000 as rewards and compensation for the loss of practice which the prosecution of his discovery had entailed upon him. It is sometimes forgotten that Jenner was no mean naturalist, and that, perhaps owing to his connexion with John Hunter, he became a Fellow of the Royal Society at the age of 39. He published his first paper on vaccination[1] in 1798, and it was only four years later that the first parliamentary grant was made. The medical officers of the navy had presented him with a gold medal in 1801, and he received the gold medal of the Medical Society of London in 1803. Thus, in five years from the date of his first publication his reputation was secure and his merits publicly acknowledged. Even if we date his public work from his first crucial experiment in 1796, the time taken to overcome prejudice and conservatism in a people so slow to move as the English of 1800 does not seem too great.

LESTER CHINESE HOSPITAL, SHANGHAI.

OVER three million Chinese sick and injured were treated at the hospital on the Shantung Road, Shanghai—the oldest and busiest institution of its kind in China—which was administered by the London Missionary Society for eighty-six years. Some of the buildings had stood for over sixty years, and had thus become ill fitted to meet the requirements of modern scientific treatment. But under the will of the late Mr. H. Lester, a British resident in Shanghai, who died in May, 1926, an adequate sum was provided for their replacement by a well-equipped modern hospital on the same site, and to commemorate this bequest the hospital has been renamed the Lester Chinese Hospital. In the eighty-second annual report it is stated that demolition of the old buildings has been completed, and till 1931, when it is expected that the new hospital will be ready, the work is being carried on in temporary quarters. During the year under review over 60,000 patients came for treatment, between them making a total of 143,517 attendances. The number of casualties due to road traffic is increasing year by year, and in 1928, 1,371 Chinese were injured by motor cars and 288 by trams. Some indication of the failure of many persons to withstand the strain of modern life is afforded by the note that in Shanghai 1,092 persons attempted suicide, the majority being Chinese women who, taking quarrels too seriously, had swallowed opium. The report comments on the need for further restrictions on the opium traffic in Shanghai, and suggests that if the drug was made difficult to obtain those seeking it for purposes of suicide would have time to calm down and change their minds. Confidence in Western medicine and surgery is growing steadily, and there is less difficulty in persuading women to enter the hospital or to undergo surgical operations; some patients, indeed, were so anxious to be subjected to operation that it was necessary to assure them that their illness did not require, and would not yield to, such treatment. The hospital has a busy and well-managed *x*-ray department, and has recently installed various kinds of electrical apparatus for diagnosis and treatment. The devoted work of the British nursing staff in training Chinese pupil nurses is specially commended. Although the hospital concerns itself primarily with the treatment of the Chinese inhabitants in Shanghai and the surrounding district, foreign residents contribute a great deal towards its financial support. The medical superintendent, Dr. J. L. H. Paterson, is assisted by a staff of British and Chinese resident surgeons, and some of the clinics are conducted under the supervision of British practitioners working in Shanghai.

PATHOLOGY THROUGH THE AGES.

DR. ESMOND R. LONG, professor of pathology in the University of Chicago, and already known as a historian of his subject, has lately brought together extracts, many of them concerning veritable milestones in the progress of medical science, from the classical writings of thirty-six fathers in pathology, from Hippocrates to Virchow. This, in a convenient form,[1] provides the student who vaguely knows the names of the describer of a morbid condition—for example, of John Hunter, Richard Bright, or Thomas Addison—with the words in which the accounts of the Hunterian chancre, renal disease, and Addison's disease were originally set out. This chronological arrangement has advantages, and as Professor Long introduces a summary of each author's work before his words are reproduced, the progressive advance of knowledge is well brought out. There are eight British authorities in the list; besides those just mentioned, Thomas Hodgkin of Guy's, Joseph Hodgson of Birmingham and London, whose account of dilatation of the first part of the aortic arch earned for him the eponymic "maladie de Hodgson," Matthew Baillie, Dominic Corrigan, and, of course, William Harvey are drawn upon. Of the three American authorities the first to be quoted is W. E. Horner of Philadelphia, who in 1829 published the first textbook of pathology in America; the second is W. W. Gerhard, also of Philadelphia, who helped to complete the work of his master, P. C. A. Louis of Paris, in distinguishing typhoid from typhus; and the third is S. D. Gross, who, ten years after the appearance of Horner's treatise, wrote a much more elaborate *Elements of Pathological Anatomy*, which Virchow years later showed as one of the treasures of his library. Lancisi (on sudden cardio-vascular death) and Fracastoro (on syphilis or the morbus gallicus) from Italy are accompanied by three less known men: Marcus Aurelio Severino, William of Saliceto, and Antonio Benivieni. The frontispiece shows Morgagni, from whose *De Sedibus et Causis Morborum* a number of extracts are given in the text. France is represented by a galaxy of eight—Jean Fernel, Jean Astruc, Bichat, Corvisart, Laennec, Louis, Cruveilhier, and Andral.

MEDICAL SCIENCE IN HUNGARY.

AFTER the war Hungary found herself deprived by the treaty of Trianon of the more valuable two-thirds of her territory, and sank into a veritable slough of despond, her intellectual life following suit to a large extent. Since the accession of the present energetic Regent (Admiral Horthy) nine years ago, she has, however, resumed her place as an active intellectual force in Eastern Europe. The University of Budapest possesses a very well-equipped medical school, and the standard of the final medical examinations is said to be unusually high. This is attributed to the fact that there is a very large population of well-educated persons who, since the territorial limitations, have been compelled to descend to the ranks of the manual labourer on account of the restrictions upon immigration imposed by other countries, and the fact that there is naturally only a limited number of posts for the brain worker. The University authorities have therefore an unusually wide choice of material. There are in Budapest three medical and surgical teaching units, the director of No. 3 (medical) unit being Professor Koranyi, to whose pioneer work on the physiology and pathology of the kidney we owe the modern renal efficiency test. The city possesses, in addition, fourteen general hospitals, including three for infectious diseases, and a magnificent Institute of Hygiene, which was equipped by the Rockefeller Foundation. Post-graduate medical work is now being organized fairly

extensively on lines similar to those obtaining in Vienna. The majority of the post-graduate students appear, however, to be drawn from France, Germany, and the Eastern countries of Europe. Many of the teachers speak English, although the lectures are delivered mostly in German or French. Much interesting original research is being conducted on the subject of rheumatoid arthritis, since Budapest contains many thermal springs and mud-lakes of proven curative value, and, therefore, large numbers of these cases are always available for investigation. These therapeutic establishments are, moreover, run in close association with the Faculty of Medicine of the University, under the professor of balneology, who is also responsible for the provision of the pathological services in connexion with these centres of investigation and treatment. Hungarian medicine appears at the moment to be in a very interesting state of active development along original, and largely clinical, lines.

THE MEDICAL DIRECTORY, 1930.

OUR old and valued friend the *Medical Directory*[1] makes its reappearance, as usual, shortly before the date inscribed on the cover. The eighty-sixth issue, for the year 1930, will be welcomed by all who need a concise and accurate guide to the members of our profession. Its contents follow the customary arrangement, and at this time of day there is little to be said in general terms about a reference book so well established in the eyes of the medical public. Turning to points of detail, we note that the letterpress has now grown by a further thirty pages, to keep pace with an increase of 391 in the number of entries. The total number of names in the present volume is 54,537, representing an increase of more than 10,000 during the past ten years, as compared with gains of four or five thousand during each of the five previous decades. Since the last edition was published there have been substantial increases in the Provinces and among registered practitioners resident abroad, and London shows a small increase; but the numbers in Scotland and Ireland have diminished somewhat, while Wales and the Services show little change. A useful feature in this year's contents list (to be found at page xxxiv, after the title-page) is the separate entry for medical benevolent societies. Dr. R. Fortescue Fox has revised his descriptive account of the spas of Great Britain and Ireland and New Zealand, and in particular the introduction to his notes on health resorts on the British coasts. The publishers, Messrs. Churchill, are to be complimented on the high standard of accuracy maintained year after year by the *Medical Directory*.

WE regret to announce the death of Mr. John Scott Riddell, C.B.E., consulting surgeon to the Royal Infirmary, Aberdeen. An obituary notice will appear in our next issue.

COSHAM PENSIONS HOSPITAL INQUIRY.

ADMINISTRATION VINDICATED.

AT an inquest, last July, on a patient in the Queen Alexandra Hospital at Cosham, Hampshire—a Ministry of Pensions hospital for severe neurasthenic cases—the jury expressed the view that very grave maladministration existed there, and urged an immediate inquiry. The Portsmouth coroner, Sir Thomas Bramsdon, was stated in the press to have associated himself with this rider, but afterwards declared that he had confined himself to the view that an inquiry was desirable. The Minister of Pensions appointed accordingly a committee of inquiry under the chairmanship of Sir Frederick Willis, lately chairman of the Board of Control; the other members were Mr. Bromley, M.P., Major Cohen, M.P., Mr. Isaac Foot, M.P., Sir Adair Hope, and Dr. E. Mapother, superintendent of Maudsley Hospital. The report of the committee, issued as a White Paper on December 10th, states:

"After carefully considering the whole of the evidence taken by us in public and in private from the patients at the hospital, and also the evidence taken before the coroner, and after fully investigating the conditions at the hospital itself, we are satisfied that there is no ground to justify the finding contained in the rider of the coroner's jury that there is very grave maladministration at the Queen Alexandra Hospital. On the contrary, we find that the hospital is well and properly administered, and we have formed a high opinion of Dr. Paul's capacity as an administrator of this institution."

The Cosham Hospital, which was opened in 1926, consists of eleven wards, with accommodation for 265 patients. The wards are arranged so as to enable treatment of various types of cases to be undertaken in self contained units. The buildings are modern, and beautifully situated, and there are workshops and recreation grounds. The case which led to the inquiry was that of a patient named Gidden, whose death was found to be due to shock caused by perforation of an intestinal ulcer, and according to the jury the shock was brought about by unnecessary violence by a monitor. The monitor was charged with manslaughter, but at the assizes no evidence was offered by the Crown, and the judge, who had studied the depositions, remarked that there would have been no chance of obtaining a conviction.

The committee took publicly the evidence of the medical superintendent (Dr. D. H. Paul), the senior medical officer, the medical officer in charge of the ward where the patient was alleged to have sustained his injury, the matron, three chaplains, and others; fifteen patients were examined at a private session, when most of them spoke in high terms of the care and attention given to them. Public invitation was given to all who had complaints to make to bring them forward. The foreman of the jury was asked to give evidence, but declined, and the Portsmouth Trades Council, which had stated that numerous complaints had reached it as to treatment by orderlies and as to the food of the patients, was also invited, but resolved to take no action. In view of certain comments by the coroner on the omission of the doctor in charge of the ward to examine the patient, the committee states that, as advised by its medical member, Dr. Mapother, in the circumstances the doctor acted according to the general rule of institutions, and was in no way blameworthy. Dr. Mapother, with another member of the committee, at an early stage in the inquiry, visited the hospital, and reported himself satisfied that no charge of maladministration could be sustained. The dietary appeared to consist of the same materials in the case of the patients as in the case of the medical staff; the nursing staff was careful and experienced, and all the provisions and precautions customary in similar hospitals were at a high level at Cosham.

On certain matters of detail the committee makes suggestions. It is of opinion that a larger proportion of the nurses should be women, and, also, that in wards containing patients with more serious mental symptoms, at least one fully certificated male mental nurse should always be present. With regard to allegations of drunkenness among patients (who, it should be noted, are not under any form of certification), the committee recommends that it should be made clear to every patient on admission that in his own interests, as well as in those of his fellow-patients, he should abstain from alcohol, and that the licensed victuallers of the neighbourhood and the police should be asked to co-operate to this end. The committee finds that the medical superintendent fully inquires into complaints by whomsoever made and of whatever nature, and has not hesitated to take disciplinary action when necessary with regard to any member of the staff. Most of the representations made to the committee by the patients were directed to securing more extensive facilities for entertainment, but this is held to be a matter for the discretion of the medical superintendent. The good work done by many patients in the workshops and grounds is the subject of commendation, and it is suggested that some system of payment might be devised by way of encouragement. The committee acknowledges the assistance it has received from Sir Lisle Webb, director-general of the medical services of the Ministry of Pensions, and from the medical superintendent of the hospital and his staff.

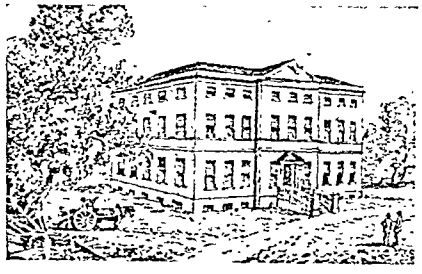
THE GENERAL HOSPITAL, BIRMINGHAM.

150TH ANNIVERSARY CELEBRATION.

WHEN the Birmingham General Hospital struggled into existence 150 years ago its founders displayed pre-eminently three characteristics, which must inevitably command success in the building up of a great medical institution. To a compassionate zeal for the relief of the suffering poor they added an interest in medical research, which was then a rarity, and they brought to the solution of their many difficulties an invincible optimism. In 1765 Dr. John Ash, F.R.S., F.R.C.P., who was practising in Birmingham—a town then of 30,000 inhabitants—drew together a little band of enthusiasts, who determined to found a hospital of 100 beds; £1,000 was subscribed at once, and an annual income of £200 was promised. Difficulties, however, quickly appeared, and the scheme seemed likely to fail; it was not until Michaelmas Day, 1779, that the hospital was eventually opened, and even then it only contained 40 beds, and an urgent appeal had to be made to the nobility and gentry to fulfil their financial promises, since money was urgently needed for administrative purposes. The original staff consisted of four honorary physicians, four honorary surgeons, and a house-apothecary. Associated with Dr. Ash as one of the physicians was Dr. William Withering who, three years before joining the hospital staff, had published his famous work in two volumes on *The Vegetables which Grow in England*, wherein was described the medicinal value of the foxglove, one of the pioneer discoveries in medicine. Five nurses were appointed at an annual salary of four guineas, to which, however, was added an additional guinea for tea and sugar, and a gratuity of one guinea "in case they behave to the approbation of the committee"; evidence is obtainable from the carefully kept minutes that some nurses were unlucky in this respect. There is an ominous note in the 1780 record that the wards were growing rather offensive; two years later the matron was directed to secure the assistance of the patients in cleansing the wards, and so relieving the nurses "whose duty in attending to

DR. JOHN ASH



1779

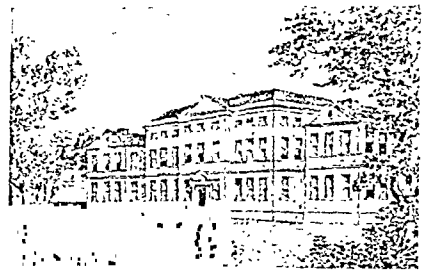
the patients seems to have been neglected in consequence of their doing such business." Even so late as 1816 it was represented to the committee "that it would tend much to the health and comfort of the patients to have the floors of the different wards thoroughly cleansed with soap and sand, and washed with hot water at least once a fortnight." In 1834 it was recommended that the floors of wards be dry rubbed instead of washed, "as there is reason to believe that the latter process is favourable to the extension of erysipelas, which at present prevails in the hospital." An interesting record of the nursing and other difficulties of this era is made public in the recent November issue of the *Nurses' League Journal* of the General Hospital. During the first hundred years of its existence many extensions and developments were required, and forty-five years ago Sir John Jaffray erected a hospital of 40 beds outside the city for the treatment of the more chronic cases which were then blocking the wards of the parent institution. Still further accommodation was soon required, however, and it was determined, in 1891, to found a new hospital; this, the nucleus of the present building, was completed in 1897. It cost just under £22,000, and was opened free from debt thanks to the generosity and the devoted labour of the late Sir John Holder, and of Mr. Barling, now Sir Gilbert Barling, who was then a member of the surgical staff and secretary to the medical committee.

DR. WILLIAM WITHERING.

Commemoration Proceedings.

On September 29th, 1929, the 150th birthday of the General Hospital was commemorated privately by the hospital staff. The more formal celebrations were postponed until December 10th, when the proceedings opened with a midday service in the Cathedral; this was attended by the Lord Mayor, Alderman M. L. Lancaster; the Vice-Chancellor of the University, Sir Charles G. Robertson; Professor J. C. Brash, dean of the faculty of medicine; and representatives of all departments of the hospital administration. The lesson was read by Dr. Stanley Barnes, senior physician to the hospital, and the sermon was preached by the Archdeacon of Ludlow, Dr. Edwin B. Bartleet, son of a former honorary surgeon to the hospital.

In the afternoon a distinguished assembly in the out-patient department was addressed by Professor K. F. Wenckebach, F.R.C.P., of Vienna, and Lord Moynihan, President of the Royal College of Surgeons. The chair was taken by Professor L. G. Parsons, chairman of the medical committee, who expressed the deep regret felt at the enforced absence, through ill health, of Sir Gilbert Barling, senior consulting surgeon, and Pro-Chancellor of the University of Birmingham. Sir Gilbert, who had been actively associated with the hospital for fifty years, had prepared an attractive retrospect of the history of the institution since its foundation; this had been published, and was presented to those taking part in the com-



1795.

memoration proceedings. In it was recalled the part played by various distinguished supporters of this institution, notably Dr. John Ash, Dr. William Withering, and Mr. George Freer, an eighteenth century surgeon renowned for his work on aneurysm, and the first who successfully tied the external iliac artery for the treatment of this condition in the thigh. Another celebrity mentioned was Mr. Joseph Hodgson, for twenty years surgeon to the General Hospital, and in 1864 President of the Royal College of Surgeons.

Professor Wenckebach, who delivered an oration entitled "The use of the foxglove by the bed-side," paid a high

tribute to the pioneer work of Dr. William Withering. The orator recalled the paper on digitalis treatment which he had read before the Section of Pharmacology at the Annual Meeting of the British Medical Association in London in 1910, and emphasized the importance of exact dosage, which, he remarked, must be a matter of careful observation in each individual case. He himself preferred to employ the titrated powdered leaves, and he admitted that on occasion he had had no hesitation in using this remedy in conditions which the textbooks held were unsuitable for it. Particular attention was devoted to various adjuvant drugs which might be associated with the administration of digitalis. Strychnine rendered most valuable help in abolishing extra-systoles, though its influence tended to wane after it had been administered for some time; better results still were obtained when it was combined with quinine. Apart from such regulation of the action of the heart, assistance in correcting disturbances of the vaso-motor system was also important. Clinical cases were cited to support the orator's contentions. Professor Wenckebach maintained that digitalis could be administered on systematic lines for many years, doses being given, for example, on alternate days; the influence of the drug reached its maximum about twenty-four hours after it had been taken.

Lord Moynihan described, with the aid of lantern slides, the growth of surgery through the ages, starting with evidence of the occurrence of myositis ossificans in *Pithecanthropus erectus*. Osteo-arthritis, he demonstrated, was endemic in Egypt in the earliest times, and tuberculous disease of the spine had afflicted Neolithic man. There was evidence of mastoid disease in Peru ten to fifteen thousand years before the Christian era. Other conditions illustrated were gall-bladder disease in ancient Egypt, atheroma of the aorta in Pharaoh Meneptah; evidence that Napoleon had suffered from undulant fever; and small-pox scarring in an Egyptian mummy. Lord Moynihan traced the growth of medical science from Egypt to Greece, and thence through the ages to the present time.

After the two orations tea was served in the board room of the hospital, opportunity being thus given for study of the portrait by Sir Joshua Reynolds of Dr. John Ash, an engraving of Dr. Withering, and the portraits of Mr. George Freer and Mr. Joseph Hodgson.

A dinner, held in the evening at the Grand Hotel, was attended by more than 450 guests, including a large number of those who had had close connexion with the hospital. The chairman was Alderman A. H. James, president of the hospital, and the menu card was adorned with illustrations of this institution from its foundation to the present time. The toast of the City of Birmingham was proposed by Lord Moynihan, who emphasized the great part played by provincial towns in the development of modern surgery. He paid a high tribute to Lawson Tait, whom he described as one of the immortals, and he recalled the great work done by Funneaux Jordan, Priestley Smith, Jordan Lloyd, Sampson Gamgee, Gilbert Barling, and Haslam. The Lord Mayor, who responded, commented on the outlook and municipal ideals of the city, and expressed the pride taken in the General Hospital. Sir John Rose Bradford, P.R.C.P., proposing the toast of "The Birmingham General Hospital," devoted himself largely to the valuable services rendered by laymen in *maintaining the voluntary* hospital system in this country. This had always commanded the services of men who had understood the point of view of the medical profession, and had been able to appreciate the great services that *medicine could* render to the community. He congratulated the hospital on the enthusiastic support it so obviously possessed. Alderman James, who replied, said that if Birmingham was to live up to its motto "Forward" it would be necessary in the very near future to obtain additional accommodation. He alluded to the proposed hospital centre at Edgbaston, and said that the city realized the importance of the undertaking to provide a new hospital, which should be at once a great teaching and research centre, and contain the most modern appliances for treatment. He believed that the appeal for funds would meet with great success. Councillor Miss Bartleet, chairman of the Board of Management, who also acknowledged the toast, gave a racy description of the hospital's life and of its efforts to preserve the highest pitch of efficiency. Dr. Stanley Barnes, senior physician to the hospital—to whose courtesy we are indebted for permission to use the illustrations in this article—proposed the health of the guests, and Professor Wenckebach replied, giving an account of the prominent part taken by Great Britain in the relief of distress in Vienna after the war.

Nova et Vetera.

CHARLES HARRISON BLACKLEY OF MANCHESTER, AND HAY FEVER.*

BY

E. BOSDIN LEECH, M.D., F.R.C.P.,

HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

CHARLES HARRISON BLACKLEY of Manchester has some claim to fame as a pioneer in hay fever research, and for two added reasons attracts attention—first, because he did his work as a general practitioner; secondly, because, like Sydenham with gout, Mark with acromegaly, Thomsen with myotonia, he recorded the symptoms of his own disease, and because he went further and used his own self for experiments made to discover the cause of the trouble and the best methods for its relief. He was willing and able to turn his own physical infirmities to the advantage of medical science.

(*Photograph by A. Reston, Stretford.*)

There must be few diseases where it is so important that the research should be carried on by a sufferer. Blackley himself points out that it is a good disease for experiment, for it is not fatal and it only lasts for part of the year. On the other hand, the experimenter lost a day's work whenever he got a positive result.

Blackley was born at Bolton on April 5th, 1820; he commenced life as a printer and engraver, working at this employment till he was 35 years old. He was from his early days an enthusiastic botanist, microscopist, and chemist. About 1855 he turned to medicine; he qualified in 1858 and practised as a homœopathist in Stretford Road, Manchester. He took a Brussels M.D. in 1874, and finally retired from practice in 1894, going to live at Southport, where he died in 1900. He had, as shown by his picture, a typical Lancashire countenance, with the curtailed beard but clean upper lip then so popular in this county.

From 1859 Blackley conducted one long series of experiments of all sorts, and he has collected the results of his investigations into a book, published in 1873, *Experimental Researches on the Causes and Nature of Catarrhus Aestivus (Hay Fever or Hay Asthma)*. A second edition, and one to which he added his ideas of treatment, was published in 1880 under the title *Hay Fever, its Causes, Treatment, and Effective Prevention*.

His claim to fame lies in the fact that, whilst others had described the disease and had theorized on its cause, he *experimented and proved it* to be due to pollen. Heberden mentions the symptoms, but does not define the disease or suggest a cause. Cullen talks of asthmatic attacks common in summer. The first satisfactory description of the disease is by Bostock, himself a sufferer, in 1819 and 1828. He gives it the name of "catarrhus aestivus," but considers it to be due to heat rather than to grass effluvia. The

* Read in the History of Medicine Section at the Annual Meeting of the British Medical Association, Manchester, 1929.

names "hay fever" and "hay asthma" seem to be due to the laity rather than to the doctors. Gordon in 1829 thought the trouble due to the aroma emitted by the flowers of grass. *Elliotson* in 1831 expressed the view that the disease was not caused by hay but by flowering grass, and probably by the pollen. Several suggestions then had been brought forward by different folk as to the cause of the attacks, the principal of these being that it was due to *ozone, high temperature* combined with dryness, high temperature combined with moisture, dust, and lastly pollen.

W. P. Kirkman appears to have been almost alone in using experiment; for, being a habitual sufferer, and seeing a single plant of *Anthoxanthum odoratum* (sweet-scented vernal grass) in blossom in his hot-house in winter, he plucked it, rubbed the pollen with his hand, sniffed it to his nose, and brought on a typical attack.

Blackley demands attention because of the systematic way in which he set himself to examine the supposed causes, and of the way in which, after proving that pollen alone is the cause of typical hay fever and hay asthma, he worked at numerous other problems connected with the disease. As he himself states, he started out to test by actual experiment the validity of the opinions held on the causes of the disease as well as to collect additional information upon points which were uncertain or doubtful.

The chief problems, then, that he set himself to solve were whether other substances than pollen cause hay fever, and if the property does belong to pollen; whether it belongs to the pollen of grasses only or to that of other plants, and, if so, to which. He also asked himself whether it was due to fresh pollen alone or also to dry pollen, and, further, whether its activity was due to a chemical or a physical agent.

A few only of the investigations he carried out throughout his working medical life whilst busy in a general practice in a big town can be mentioned. He experimented with the air in the town, comparing it with that on the edge of the town and that of the hayfields in the country a few miles outside the town. He tried all sorts of grasses and flowers, choosing certain fields in turn according to the crops growing in them. He says that he experimented with thirty-five different natural orders. He regulated his holidays to sea or country that he might try new areas for his investigations. Then, too, his investigations were carried on both with fresh pollen and with the dry pollen of grasses, with which he impregnated the air of rooms in his house for experimental purposes. Youthful visitors to his house considered him a harmless crank when they were taken from one room to another where different grasses were wafted about. He also experimented with air filtered through layers of muslin impregnated with drugs, living in a room thus protected right in the middle of the country where the air was loaded with pollen. In this he devised apparatus to ensure sufficient passage of purified air through the building. He carried out a similar experiment by breathing air through a box in which a filter sieve was present. He could carry this about with him, and, counting the number of respirations, could judge the amount of air breathed. He devised little silver plugs of the shape of shoes, the soles consisting of fine gauze, which he wore in the nostrils.

To judge the amount of pollen present while he was experimenting thus he devised an apparatus of great ingenuity, by which a sticky surface of definite size was exposed for a fixed time to pollen-carrying winds or atmosphere, and on which he later laboriously counted the pollen granules which were found to adhere. At the same time he often remained in the neighbourhood of his apparatus and kept an accurate diary of the severity of his attacks, comparing the number of pollen granules collected with the amount of catarrh which resulted. In one year these experiments were carried on in the country daily for the whole pollen season, from early April till August. The next year he experimented with the pollen in the town. He even devised a kite some six feet by three in size, which carried his adhesive surface and also a clockwork apparatus to limit the time of exposure, and this kite he flew at various heights so that he might learn the amount of pollen in the upper air.

In testing the effect of pollen on the eye he so arranged his pollen-counting apparatus that the adhesive surface formed part of his glasses; he was thus able to count the granules which would have fallen on the conjunctiva if it had not been protected. To work out the active principle of the pollen he experimented with tinctures and infusions, applying these to the mucous membranes. He also tested the susceptibility of the tongue, lips, and fauces to the pollen. Finally he experimented on the skin, scarifying the surface, rubbing in preparations of the various pollens, and watching the local reactions, much as is done nowadays by specialists in asthma.

In giving his results it is obviously of no value to go step by step through the experiments by which he arrived at them. One wants only to show his ingenuity and his pioneer work.

By his series of experiments with his supposed causal agents he excluded them one by one—dust, ozone, heat, and many others. He took great care to exclude contaminations of one agent with another. Pollen alone, he found, would cause the attack; some other agents might irritate susceptible people, none would cause the typical attack. Then, again, flowering grass, and not hay, was the usual cause. The pollens of all grasses and that of certain other plants were the chief offenders. As he says, plants belonging to the *Graminaceae* have this property to a more marked degree than others; but there are plants belonging to other orders which have it in an equal or almost equal degree.

He comes to the conclusion that the toxicity of the different sorts does not depend on the size or visible characteristics of the granules; and that watery and alcoholic extracts of pollens applied to the nose are not irritant.

Weather influences hay fever insomuch that moisture prevents the spread of pollen, whilst heat, dryness, and wind all help to disseminate it. Dry pollen spreads quickly, but even where there is much dry grass in a room there is little chance of hay fever, because there is no wind to waft it about; it sinks, and but few pollen granules are caught on the sticky surface. On the other hand, as much was found in the higher air as near the ground level. This he proved by his kite experiment.

He showed on himself that the amount of pollen necessary to bring on an attack is very small, but is quite definite. There is, in fact, a threshold of immunity—where the granules caught on his apparatus were below a definite number he was free; so soon as they rose beyond the limit he had an attack, and beyond this toxic point the symptoms were closely related to the number of granules. He also showed that the nose was the most susceptible part; that the eyes were irritable to pollen, but did not start severe attacks; and that inhalation (with nose and eyes protected) caused an asthmatic attack rather than hay fever. His skin reactions were weak or negative, but once when returning from the country he carried flowering rye in his hat and found that he got a severe head rash.

While Blackley devised no apparatus such as could generally be used by sufferers, he did prove that he himself, suitably protected, whether by nose-shoes or by muslin, could live in the midst of hay fields without suffering. He surmises that an immunity can be acquired in early life, since the fewest cases of hay fever occur in a class most likely to come in contact with the cause of the disease—namely, farmers.

It is always difficult to gauge the exact value of a man's work where others are interested in the subject at the same time, but it seems that we can claim that Blackley was the first who brought extensive experimental evidence to show that pollen is the one cause of hay fever and hay asthma, and that though people who are susceptible will be irritated in other circumstances, such as dust and heat, still pollen is the one cause.

In his lifetime, Blackley, like many pioneers, was looked upon as somewhat of a faddist—a man who played with grasses—but he was one of whom England and Manchester may be proud. It is from America that inquiries as to his work and his life history chiefly emanate; he has certainly not been sufficiently recognized in England.

BRITISH COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS.

FIRST GENERAL MEETING.

THE first general meeting of the Fellows and Members of the British College of Obstetricians and Gynaecologists was held in London on December 3rd, with the President, Professor W. BLAIR BELL, in the chair.

In proposing the adoption of the report of council and the balance sheet, the President reminded Fellows and Members that as the College had been incorporated as lately as September 13th the report was very brief, and the balance sheet represented for the most part the financial arrangements prior to incorporation, though it also showed the receipts and outgoings for the first two months after incorporation. While registration receipts for fellowship and membership and the annual subscriptions would be sufficient, perhaps, to keep the College going as it was at present conducted, they would be inadequate to liquidate the expenses when a College building was established in London. Until, however, they had a home and all the appurtenances fitting to their status they would find it hard to create those traditions that surrounded all lofty endeavours and that pride in the College which made for loyalty and prestige. The treasurer hoped, therefore, to establish three special funds—namely, an endowment fund, a house and furnishing fund, and a fund to wipe out the liabilities in connexion with the incorporation and pre-incorporation expenses. The endowment fund, though unlimited, should not be less than £100,000; for the house and furnishing fund they should aim at £30,000; and for the preliminary expenses £1,600. Lord Riddell had generously given £1,000 for general purposes, and other benefactions had been promised. It was hoped that not only Fellows and Members, but others, including the lay public, would assist with contributions, for a College that was working for the good of the community had some claim on the generosity of those interested in maternal welfare.

It seemed, continued the President, that there were still doubts about the structure and functions of the College, and it might be well, therefore, to sketch briefly its constitution and the part it was now playing, and might, it was hoped, play in the future. Incorporation, without the use of the suffix "Limited," was the present legal status of the College, and this gave it certain financial advantages in regard to trusts and other matters. Nevertheless, the present state should be regarded as a stage only in the progress towards the dignity of a Royal Charter; but for the attainment of this the College must prove its worth, not only to obstetrics and gynaecology and to the medical profession, but also to the State. In the oath (*British Medical Journal*, October 5th, p. 632) to which all Members and Fellows subscribed, they expressed their ideals of loyalty, progress, and service.

The council hoped to elect as foundation Fellows of the College practically all the senior obstetricians and gynaecologists in England, Scotland, Wales, Ireland, and the British Dominions; and as foundation Members, who would subsequently become eligible for the Fellowship, the less senior obstetricians and gynaecologists. Already a majority of those approached in Great Britain and Ireland had joined; so far, in regard to their colleagues in the British Dominions, only a preliminary list of names had been drafted. It was not intended to elect as Fellow or Member anyone who was not engaged exclusively in obstetrics and gynaecology, but there would be a certain latitude—for example, in the case of those in the public health service.

Those responsible for founding the College, said Professor Blair Bell, had turned no envious eye on more venerable institutions; they had invited no antagonism from them. Rather they hoped that the College might be permitted, without dispute, to help in a corporate manner those with whom its Fellows and Members had formerly worked as individuals. Though they had made their way through the difficult and devious paths of negotiation on which misunderstandings found fertile soil, they would, he believed, when all the documents had been studied, be held to have conducted their part honourably. Soon the council hoped to discuss with the Royal College of Physicians of London, and the Royal College of Surgeons of England, the details of the granting of a diploma in obstetrics and gynaecology, for the drafting of the regulations for which a committee of the College had been sitting. While the College was still struggling with the difficulties of financial and administrative organization, affairs of State had claimed its attention, and it hoped to place its services at the disposal of the Government, which intended to take action in regard to maternity problems, and had asked the College for assistance and advice.

Finally, the President referred to the necessity under which the College had found itself to devise a machinery which would enable the first steps in its formation to accord with its constitution and with legal procedures generally. The council of signatories which had been developed from the original preliminary committee had no alternative but to elect the first full council, which had then drafted the list of names of those to be invited to become foundation Fellows and Members. While such methods had undoubtedly been proper and necessary, it might be held that the College would not carry full weight until the council had been elected by the vote of the Fellows and Members, and the officers by the same method or by ballot of the council. It was desirable, therefore, to get rid as soon as possible of the disadvantages associated with the existence of a self-elected council. He had suggested—and the members of the council had unanimously agreed—that in the next few months every member of the council should voluntarily resign and offer himself for election, along with others duly nominated. From what he had said it would be clear that if the College was to justify its existence it would need the very active support, based on real interest in its endeavours, of every obstetrician and gynaecologist.

Canada.

[FROM OUR CORRESPONDENT IN MONTREAL.]

The Control of Bovine Tuberculosis.

MUCH progress is being made in dealing with bovine tuberculosis in Canada, and as the scope of the work increases it is found that the demands from the livestock owners become more persistent. One of two plans is followed. Under the "accredited herd" plan the owner receives compensation for cattle showing positive reactions. This plan is limited to herds containing at least ten registered pure-bred cattle of one breed, six of which are over six months of age and one of them a herd sire not less than a year old; the registered cattle must comprise at least one-third of the entire herd. The second plan concerns those owners who cannot qualify for the other one; no remuneration is received for reactors. Since the inception of tuberculosis control policies about 130,000 tuberculous cattle have been slaughtered and the premises on which they were found have been cleansed and disinfected. About one-seventh of the total number of cattle in the Dominion have been tuberculin tested once, and many of them several times, by officers of the Health of Animals Branch. Certain areas have been established as "restricted," and general tests are carried out in these at successive periods. The result has usually been that a progressive lowering of the proportion of infection is revealed. In Prince Edward Island, for example, which was established as a restricted area in 1925, tests then showed 0.59 per cent. of reactors, for which compensation was paid to the extent of 14,194 dollars. The second general test is now being made in this province; it was delayed on account of the low percentage of infection and the natural isolation of the province. The result so far shows 0.16 per cent. of reactors, and 2,976.00 dollars has been paid in compensation. This type of result repeats itself throughout the Dominion wherever these restricted areas exist.

The Hippocratic Oath.

It has recently been pointed out by the secretary of the Medical Faculty of McGill University that, despite a general impression to the contrary, the Hippocratic Oath has never been used as part of the ceremony of graduation of medical students at McGill University. The form of

declaration used by the graduating student has been changed more than once. The first—used in 1833—was a short and simple pledge. In 1842 this was lengthened, and the details of what was required of a medical man were stated rather more formally. Then, the following year, the Faculty of Arts was formally opened, and in that year the Faculty of Medicine put its oath into Latin, although it is not recorded whether the change was made because classical knowledge was now available, or merely in an attempt to sustain and increase dignity! In any case the change was made at about the time that the Medical Faculty of McGill University lengthened its course from three to four years—the first school on the American continent to do so. The form of the oath is based on that of Hippocrates, but it is pointed out that the exact phrasing of the latter cannot be used, since it prohibits the practice of surgery.

Scotland.

Health of Scotland.

THE quarterly return of the Registrar-General for Scotland for the period ending September 30th, 1929, shows that there was a birth rate of 18.7 per 1,000, and a death rate of 10.8 per 1,000. This is the lowest third quarter birth rate yet recorded, the previous lowest being 19.0, which was recorded in 1917 and again in 1927. The death rate is 2.2 less than that of the previous quarter, but approximately the same as that of the third quarter of the preceding year. The infantile mortality rate of the quarter was 62 per 1,000 registered births, which is 14 less than that of the previous quarter, and 7 less than that in the third quarter of last year. The death rates from all forms of tuberculosis and from tuberculosis of the respiratory system were respectively 78 and 54 per 100,000, which are the lowest rates recorded up to this time in Scotland for any quarter. Deaths from malignant disease numbered 1,807—equalling a death rate of 146 per 100,000—and these were 125 more than in the third quarter of last year. With regard to the causes of death, 3.4 per cent. were attributed to the principal epidemic diseases. Epidemic diseases other than those grouped as the principal epidemic diseases were cerebro-spinal meningitis, responsible for 42 deaths, encephalitis lethargica for 29 deaths, erysipelas for 31 deaths, and acute poliomyelitis for 5 deaths. Pneumonia accounted for 5.8 per cent. of the total deaths of the quarter, equalling a death rate of 63 per 100,000, but these deaths were 88 fewer than in the third quarter of last year.

Maternity Service in Scotland.

An address was delivered by Dr. J. Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland, on December 11th, to the Edinburgh Women Citizens' Association. Dr. Kinloch demonstrated by means of charts the high rate of maternal mortality in Scotland as compared with that of other countries. Scotland, he said, was the worst in the world in this respect, for roughly 7 mothers died every year out of every 1,000 who gave birth to children, and for every 1,000 who died, 14,000 developed serious impairment of health. Death was due in one-third of the cases to septic infection contracted at the time of the birth; in another third it was due to toxaemias developing during the later months of pregnancy; and in the remaining third it was due to haemorrhages connected with confinement, most of which were really septic in origin, and to injuries connected with difficult birth. The best conditions for confinement were a healthy home with midwife and doctor in attendance. In a city like Glasgow, however, where 65 per cent. of the million and a quarter inhabitants lived in one- or two-roomed houses, it was impossible to provide the healthy home, and the people must be got into better living conditions. By bacteriological control of the staff and patients of a hospital infection could be prevented, and in this connexion an important experiment was taking place at the Elsie Inglis Maternity Hospital in Edinburgh. If immediate treatment was received when conditions were abnormal, the majority of the mothers could be saved, but this needed careful organization and staffing of maternity institutions. Next in importance was proper ante-natal care, and this could be provided without new legislation; what was necessary was to put into operation already existing machinery.

Edinburgh Public Health Department.

A lecture was delivered under the auspices of the Combe Trust, on December 11th, by Dr. William Robertson, medical officer of health for Edinburgh. The lecturer said that it was regrettable that a public health department was a purely spending concern; nevertheless the continually growing expenditure produced results in the direction of saving life. Although such devastating diseases as typhus, cholera, and typhoid fever had been virtually extinguished, the commoner epidemic diseases still clung to the community, and this was unavoidable because infection was usually spread in schools. Education had done much to induce parents of children to call in medical aid at an early stage. Measles and whooping-cough were the most fatal among the infectious diseases, and this ought to be universally recognized. As evidence of the good results that might be achieved by improving environment, tuberculosis might be cited, and infantile mortality was another condition which had declined owing to the same measures. The furthering of the provision of better housing conditions was at the present time one of the principal activities of the public health department. This work was constantly in progress, because a large staff of officers working under the chief sanitary inspector was daily visiting houses to note their good, bad, or indifferent features. No other community had done so much as Edinburgh during the past six years to provide better houses in sufficient numbers and at sufficient speed. In this period a population of nearly 30,000 had been provided with alternatives to insanitary and undesirable homes. A scheme which was now in prospect was perhaps the largest that had yet been undertaken in Scotland. It would consist in clearing out 1,600 faulty houses in the St. Leonard's district, with the erection of alternative dwellings, and would cost over £800,000. An unfortunate complication of slum clearance at the present time was that unemployment affected many of those who were in need of better accommodation, but who were unable to pay the higher rents for the new municipal houses. The lecturer drew attention to the severity of many of the municipal housing schemes which were to be noticed in various parts of the country, and emphasized the desirability in housing schemes of having shrubberies, open spaces, and a well-studied distribution of trees.

Ireland.

Motor Vehicle and Road Traffic Bill.

THE Northern Ireland Parliament has adopted in the Motor Vehicle and Road Traffic Bill, now under consideration, a new definition of what constitutes "drunkenness" as applied to a person in charge of a motor car. For the words in the former Act "drunk while in charge on any highway or other public place of a motor car," the following have been substituted: "Found when driving or attempting to drive, or when in charge of a motor car on any highway or other place, to be under the influence of drink or drugs to such an extent as to be incapable of having proper control of the vehicle." This new definition carries out the proposal of the British Medical Association's Committee on Tests for Drunkenness that the word drunk should always be taken to mean that the person concerned was "so much under the influence of alcohol as to have lost control of his vehicle to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time," and conforms with the definition adopted in the Road Traffic Bill, introduced by Earl Russell in the House of Lords (*British Medical Journal*, December 7th, p. 1079) in which the phrase used is "under the influence of drink or drugs to such an extent as to be incapable of having proper control of the vehicle." Speaking in support of the new clause the Parliamentary Secretary to the Ministry of Home Affairs, Northern Ireland, said that it was essential

that a man in charge of a motor car should be sober enough to drive it and control it without being a danger to those who had just as good a right to the use of the road. The clause was agreed to on December 6th, and the bill passed through committee.

Treatment of School Children in Northern Ireland.

At the last meeting of the management committee of the Fermanagh County Hospital, in a discussion arising out of Dr. Kidd's refusal to operate on a child sent by the regional committee for treatment (*British Medical Journal*, November 16th, p. 925). Dr. Kidd read the sections of the Education Act dealing with the medical treatment of school children, and said medical treatment schemes were not intended for the children of parents who were able to pay the cost of treatment by a private practitioner. His action in not carrying out this operation was actuated by a desire to impress upon the regional committee that by including such cases in their treatment scheme they were diverting Government grants from the purpose for which they had been intended—namely, to cover the cost of the treatment of children whose parents were unable to pay for treatment in the ordinary way. He submitted that any agreement made between the hospital and the regional committee must be subject to the intentions and requirements of the Act, and one of the first duties of the regional committee was to inquire if the parents were able to provide the treatment required by their inspecting medical officer. Had he accepted the child in question the hospital would have been paid 5s. a day, and if the child came in as a private patient the hospital would have got 10s. a day. After discussion the management committee decided to send a reply to the regional committee, stating that it was quite satisfied that Dr. Kidd had acted in accordance with the terms and intentions of the Education Act (N.I.), 1923, with regard to children attending primary education schools, and particularly in accordance with the requirements of the circular entitled "Education (Medical Inspection and Treatment of School Children) (Northern Ireland) Regulations, 1924," issued by the Ministry of Home Affairs.

Road Accidents and Hospital Finance.

Dr. F. B. Clery, Richmond Hospital, Dublin, in a recent address in Dublin, said that scarcely a day passed without bringing its toll of injured to the hospitals, and in spite of many suggested remedies for that state of affairs the numbers kept on increasing. By the education of motorists and road users much was being done, but there would always be thoughtless people, not to mention children, the aged, and the infirm. Recent agitation in favour of compulsory third-party insurance of motorists had given rise to the question of payment to hospitals for the maintenance of those who were injured in road accidents. It was unjust that hospitals should be expected to treat those cases without payment for maintenance. By the treatment the liability of those responsible for the accidents (or the insurance company) was dimmished; yet the hospital had no claim in law against them. As a result the loss so incurred had to be made up from moneys intended for the relief of the sick poor. The injured party might recover hospital expenses, in addition to other damages, but the hospital bill was often forgotten.

England and Wales.

London School of Medicine for Women: Annual Dinner.

THERE was a very large attendance at the annual dinner of the London (Royal Free Hospital) School of Medicine for Women, held at the Savoy Hotel on December 5th, and presided over by Mr. Joseph Cunning, senior surgeon to the hospital. Lady Emmott, member of the association of the school and of the board of management of the Royal Free Hospital, proposing the toast of "The School and Hospital," said that the school had a wonderful record of successes. The presence of so many distinguished women in that room should be an inspiration to those who were following them. Great gratitude was due to the men of the Royal Free Hospital, who had admitted women as students and who had done so much to further their education in medicine. As one deeply interested in the welfare of women she regretted any setback to their progress, such as the recent decision of several hospitals to refuse admission to women students. It was a very good thing for men and women to be able to work together as they did on the staff of the Royal Free Hospital, and she hoped that in the long run this example would have its effect. Mr. Cunning, on rising to reply, had a most enthusiastic reception. He recalled the names of several of the eminent men connected with the hospital—Mr. Boyce Barrow, who at 82 was still hunting and hoped to breed a Derby winner; Sir James Berry, that most stimulating colleague, who, by dint of asking every three months, for the space of two years, secured operating theatres which were the admiration of all London; Mr. Edmond Ronghton, noted for always calling a spade a spade; Dr. Carr and Dr. Pheat, two great clinical teachers; Sir Farquhar Buzzard; Mr. Alfred Langton, whose magnificent gifts would always be remembered; Lord Riddell, the president of the hospital and chairman of the weekly board, who did invaluable work in both capacities; and Sir Albert Levy, the present most generous honorary treasurer. The Eastman Dental Clinic would give additional space and facilities to the hospital, and the best thing for women to do, instead of trying to gain admission to the men's schools, was to try to increase the number of beds at the Royal Free. The outstanding educational success of the year had been the winning of the University Medal in oto-rhino-laryngology by Miss Mildred Warde, a former student and present member of the school and hospital staff. Dr. Hazel Chodak Gregory who was received with cheers, proposed the toast of "The Guests," among whom were Viscountess Rhondda, the Lady Emmott, Sir Patrick Hastings, K.C., Sir Walter Schroeder, Dr. Chi-holm of the Manchester Babies' Hospital, Dr. Ethel Bentham, M.P., Dr. Deller, the new Principal of the London University, Mr. Rew, secretary of the Conjoint Board, Sir Squire Sprigge, Dr. N. G. Horner, and Dr. McNair Wilson. Sir Patrick Hastings replied for the guests in a very witty speech, and Lady Rhondda, following, made particular mention of the fine piece of co-ordinated research now being done at the Marie Curie Hospital, largely staffed by former students of the Royal Free Hospital. Miss Bolton, senior surgeon to the Elizabeth Garrett Anderson Hospital, proposing the health of the chairman, said that she was glad of this opportunity to tell Mr. Cunning how much all past and present students owed to him. She remembered how skilfully, as senior resident, he had combined care of the patients with excellent teaching of the students, and recalled Saturday afternoon classes before the final examinations, to which many people owed their success. His elegance of poise and finish and his unruffled dealing with any emergency were an inspiration to all who saw them, and she was glad to feel that Mr. Cunning's skill and experience were still available to both students and patients. At the conclusion of the speeches the company adjourned to the dancing hall.

The League of Mercy: Thirtieth Anniversary.

The thirtieth annual meeting of the presidents of the League of Mercy took place at St. James's Palace on December 11th. The Prince of Wales, the Grand President, accompanied by the Lady Grand President, Princess Mary, Countess of Harewood, took the chair. The following message was read from the King: "On the thirtieth anniversary of the foundation of the League of Mercy, the Queen and I congratulate the presidents, vice-presidents, the members, and all who have worked so loyally for its support upon the success of their endeavours, by which a total contribution of £567,000 has been made towards the voluntary hospitals of the country. Such support, coming as it does from all sections of the community, proves that the present generation are as anxious as were the past to maintain the noble traditions and splendid achievements of our voluntary system. It is indeed gratifying to me that the Grand President and Lady Grand President of this inspiring organization are members of my family." The Prince of Wales, after speaking of the new charter under which the league would shortly be working, and which would furnish an opportunity of increasing the numbers of those serving on the

council, went on to address the presidents on the general hospital situation. As a result of recent legislation, said His Royal Highness, the councils of the county and county boroughs were endeavouring to bring all hospitals into closer touch with one another. "It seems clear that authorities generally still recognize the importance of retaining the voluntary system, so that any minor changes which do occur in the organization of voluntary hospitals will be directed towards co-ordinating their work with the other types of hospital administering to the health of the community. It will therefore still be the privilege of the workers of the League of Mercy not only to continue the support they have given in the past, but also to persuade people to open up fresh districts wherever an opportunity offers. It is only by this means that we can successfully compete with the ever-increasing financial demands of modern medicine and surgery. . . . Disinterested service remains our object, and in this spirit I wish you all success in your activities during the coming year." The Prince then made several presentations of the Order of Mercy, and three ladies were invested with the bar to the Order. Lord Marshall, honorary treasurer, said that the income for the year had more than equalled last year's total. The grand total of income was £26,400, compared with £26,143 in 1928. The donation made to King Edward's Hospital Fund was £17,000, and the grants to extra-metropolitan hospitals amounted to £8,399, making a total of £26,399, compared with £25,200 the previous year. Lord Moynihan of Leeds then gave an address, in which he expressed to the members of the league the profound respect and congratulations of the medical profession for all that they had done for the hospitals. There never was a time when hospitals were so well equipped, so well served by members of the medical profession, or held in such high public esteem. The effect of the new Local Government Act would be that the number of beds available for patients would be more than doubled, but Lord Moynihan reminded the company that while the number of beds would be doubled, it was not possible at the same rate to increase the number of officers—physicians and surgeons, and other members of the staff—necessary for carrying on the work. It was therefore essential that progress in connexion with the new hospitals should be slow until sufficient time had elapsed for the training of the necessary personnel. He urged the League of Mercy to extend its excellent efforts. The proceedings closed with a few words by Princess Mary in response to a vote of thanks.

British Institute of Radiology.

The proceedings at the annual meeting of the British Institute of Radiology, held in London from December 4th to 6th, were reported in last week's *Journal* (p. 1117). The congress ended with a dinner at the Trocadero Restaurant, under the chairmanship of Mr. C. Thurstan Holland. In reply to the toast of "The Institute," proposed by Mr. Cuthbert Andrews, who referred wittily to some reforms and innovations, Mr. Thurstan Holland said that the congress had been particularly notable for the lecture given by Professor Forssell, whose careful statement on the relative position of radiotherapy and surgery would do much to correct exaggerated notions in the mind of the public, and also in the mind of the medical profession. Radium would do much for cancer, possibly in many ways more than surgery, but it was not an absolute cure for it, and the way of progress lay in the skilful and well-informed combination of methods to suit the individual case. Major C. E. S. Phillips proposed the health of the several distinguished guests who were present, and replies were forthcoming from Professor S. A. Eddington, who spoke of his interest in the application of the knowledge of *x* rays to stellar phenomena; Mr. Donald J. Armour, president of the Medical Society of London; and Dr. G. W. C. Kaye, superintendent of the physics department of the National Physical Laboratory, and a former president of the Institute. Professor Forssell proposed the health of the president, Mr. Thurstan Holland. Speeches were shortened in order to permit the performance of a very clever skit described as a "radiological drama in about one act," and entitled "Blood and whitewash." The principal characters were Dr. Buryan Hope, a radiologist, Miss Trixie Manners, a very casual young lady who had drifted into the profession of radiography, and Mr. Carver Small, a surgeon. The burlesque, the work of an unknown author, who unites a caustic pen with an intimate acquaintance with radiological experiences, was received by the company with much appreciative laughter.

The Old Epsomian Club.

The fifty-second annual dinner of the Old Epsomian Club was held at the Wharncliffe Rooms, London, on December 12th, and attracted an attendance equal to the record achieved in the preceding year. The chairman, Brigadier-General G. T. Mair, C.M.G., D.S.O., who is president of the club, proposed the toast "Floreat Epsomia," and contributed reminiscences of the earlier days of the school. He contrasted the position then with the great success attained during recent years, and commented on the various structural and other improvements that had been effected. The headmaster, Mr. A. C. Powell, replied, and gave his usual report on the outstanding features of the previous twelve months. Insisting that the club and school were really one organism, he expressed his satisfaction at the excellent growth of the former, and anticipated further expansion in the near future. In a sympathetic tribute to the late president of the school, Lord Rosebery, he remarked that death had removed one who had been a real working president, and whose example seemed likely to be followed by the new president, Lord Burnham. The school had won an exceptional series of successes in all departments, both scholastic and athletic, and a high percentage of passes had been obtained in the preliminary medical and other examinations. The year had been noteworthy for the decision of St. Thomas's, Charing Cross, and Guy's Hospitals to establish special scholarships for Epsom boys. The Officers Training Corps had been awarded a highly laudatory certificate. The cricket season had been very successful, and the present football team was one of the best ever known; indeed, prospects began to appear of founding an Old Epsomian Rugby Club. In his usual inimitable style Mr. A. C. A. Parkinson proposed the health of "The Guests," twitting various of them with what he regarded as their foibles, and Dr. A. Middleton Hewat responded. In the course of the evening Sir Cecil Armitage, who was president two years ago, presented the Old Epsomian golf cup to the winner, Mr. H. G. L. Hughes.

Correspondence.

MEMORIAL TO WILLIAM HARVEY.

SIR,—It is gratifying to know that attention is directed once more towards the ruined tower of Hempstead Church, where lie the remains of William Harvey.

The last lengthy conversation I had with the late Sir Dawson Williams turned on this subject, which lay near his heart. We parted on the understanding that if, after consideration of all the circumstances, he found a fitting opportunity during the year of my presidency of the Association, he would signal to me and I would take occasion to urge the claims which the ruined tower had on the British Medical Association. A day or two later I paid a pilgrimage to Hempstead and was convinced of the propriety of the claim.

As nothing emerged up to the time when Dawson Williams was suddenly called from us, I concluded the proposal would probably mature in connexion with the celebration of Harvey's tercentenary. Sharing the disappointment of many that nothing further transpired publicly, I was pleased to read Dr. Michael Grabham's note in the *Journal* of December 7th (p. 1072), and to learn that a further move has been taken towards the rebuilding of the tower of Hempstead Church.

We are *not* concerned with the repair of a collapsed church tower, but rather with the occasion which the ruined tower over the bones of William Harvey affords us to record our veneration for him, who inspired modern medicine, by ensuring that the church of Hempstead shall remain to all time a fit shrine for the sacred ashes.

The replacement of the fallen tower must appeal convincingly to hundreds of grateful and generous minds within the Association, as indeed it will appeal to the wider circle of doctors and biologists throughout the world. If the claim be properly presented in the proper quarters, I am satisfied it will be met. The British Medical Association is assuredly one of the proper quarters, and the members of the British Medical Association will not fail to respond to the best of their ability.—I am, etc.,

University of Edinburgh, Dec. 9th. R. W. PHILIP.

END-RESULTS OF OPERATION FOR GASTRIC AND DUODENAL ULCER.

SIR,—Before drawing conclusions from Dr. A. P. Luff's interesting analysis of the after-history of gastro-enterostomy, published in your issue of December 7th (p. 1074), attention should be paid to certain fallacies which, though perhaps inevitable in this class of statistical inquiry, yet require careful consideration.

1. It is misleading to assume that, because 66.6 per cent. of the 671 duodenal ulcer patients about whom the necessary information was forthcoming had no pain or discomfort after the operation, the same percentage would hold good for the remaining 324 cases (32.5 per cent.), in 232 (23 per cent.) of which no after-history at all was obtained. These 232 include an unknown, but possibly considerable, number of deaths and ill results. No information would be obtained in a considerable proportion of hospital cases in which death had occurred, as well as in many of those in which the after-results were so bad that the patient could not work and consequently had to leave the neighbourhood.

2. The period of two to nine years which has elapsed since operation is not sufficient to justify the term "end-result" used in your leader, as many jejunal ulcers only develop after several years of freedom from symptoms. In one of my cases perforation of a recurrent duodenal ulcer occurred after fourteen years of freedom from symptoms and a jejunal ulcer perforated three years later. I have had four cases of gastro-jejuno-colic fistula under my care, the fistula having formed six, eleven, twelve, and nineteen years respectively after the gastro-jejunostomy, so that at least three of the four would have escaped tabulation in Dr. Luff's report.

3. It is stated that the incidence of jejunal ulcer is only 2.8 per cent. Apart from the 23 per cent. of patients in whom no after-history was obtained and the possibility that this complication may yet develop in some of those who are still well, it is obviously fallacious to assume, as has been done, that it was only present in the cases in which it was actually found at operation. Almost all of the additional 2.4 per cent. of cases in which haemorrhage occurred between one and seven years after operation, and the 6.1 per cent. of cases with severe pain, must have had a jejunal ulcer, as well as a good many of the 27.3 with temporary or occasional slight pain. The total incidence of jejunal ulcer must therefore be at least 10 per cent., and it is probably considerably higher.

In your leader on the "end-results" the danger of perforation and haemorrhage is greatly exaggerated. It is impossible to draw any reliable conclusions from hospital statistics as to the frequency of perforation, as almost every case of perforation occurring in the neighbourhood of a hospital will be admitted, but only a comparatively small proportion of all cases of ulcer. With regard to haemorrhage Dr. J. J. Conybeare found that only about 2.5 per cent. of patients admitted to Guy's Hospital for severe haemorrhage died. As haemorrhage occurs in about 20 per cent. of ulcer cases, the actual mortality from this cause in ulcer is 0.5 per cent., or only one-fortieth of the estimate given in your leader. It is necessary to add that of the twenty-three fatal cases of haemorrhage in Guy's Hospital between 1911 and 1920, no fewer than ten had previously undergone some operation on their stomachs.—I am, etc.,

Windsor Forest, Dec. 9th. ARTHUR F. HURST.

POST-GRADUATE OPPORTUNITIES IN LONDON.

SIR,—The Fellowship of Medicine and Post-Graduate Medical Association would be grateful if you would publish this letter for the benefit of medical men and women intending to visit England.

We have heard overseas graduates complain that London is so large, and so complicated, that it takes a few weeks to learn the way around; they also say that, unless they come armed with letters of introduction to physicians or surgeons, it is difficult to obtain the facilities they require. The Fellowship of Medicine was founded to overcome these difficulties, and overseas graduates should, as a matter of course, come direct to the Fellowship, where, without any charge, they can obtain information, advice, and assistance. We can—and every day do—save time for overseas graduates who apply to us either before leaving their own country or on arrival in England.

It is frequently mentioned that foreign post-graduate schools are attracting many of our doctors on account of better organization, and we feel sure that this idea is prevalent owing to lack of advertisement of our own activities—hence we are writing this letter to the medical journals in the British Empire. Increased support given to this organization by graduates means added facilities for study.

Perhaps the main point to be realized is that in England the medical year begins in October, and extends through the winter and spring until the end of July; August and September being the vacation months, opportunities for work are naturally somewhat curtailed, though the Fellowship endeavours to provide facilities for doctors who are only free for study during that time. We would add, however, that for overseas doctors their arrival in England in August or September means that they will have ample time to settle down and become acquainted with London before starting work in earnest.

We have been told that the information chiefly desired by overseas practitioners is the dates of the various examinations for degrees and diplomas, and the dates, duration, and opportunities for securing resident positions in London hospitals, as well as the facilities for special courses of instruction. All this information the Fellowship of Medicine is in a position to provide.

As far as the Fellowship itself is concerned, opportunities for clinical work all the year round are provided in the forty London hospitals with which it is associated, as well as the special courses, and also weekly (free) lectures during the winter months, and weekly (free) clinical demonstrations (except during August and September). In addition, the Fellowship publishes monthly the *Post-Graduate Medical Journal* (6s. per annum, post free), containing post-graduate lectures, clinical demonstrations, reports of cases, and information on the various courses of instruction. Above all, however, the Fellowship endeavours to help in every way possible medical practitioners requiring advice and assistance, by acting as a central bureau of information, and, of course, no charge is made for this service. All inquiries should be addressed to the secretary, Fellowship of Medicine, 1, Wimpole Street, London, W.1.—I am, etc.,

H. W. CARSON,
Chairman of Executive Committee,
London, Dec. 4th. Fellowship of Medicine.

THE TREATMENT OF SCOLIOSIS.

SIR,—I have read with great interest Mr. McCrae Aitken's paper on the treatment of scoliosis in your issue of November 23rd (p. 939), and I quite agree that the profession as a whole entirely neglects the rotation element in scoliosis. It appears to regard it as secondary to the lateral bend, and to suppose that all that is needed is attention to the latter, the cure of which will *per se* bring about the cure of the former. Concerning the methods usually in vogue for estimating the degree of scoliosis, this, as ordinarily practised, is quite unscientific. Scoliosis consists of lateral curvature and rotation in combination. It is therefore misleading merely to measure one portion of it—namely, the lateral curve. With the aid of a

torsionometer of my own design[1] I have proved to my satisfaction that apparently similar cases of lateral curvature exhibiting the same amount of lateral deviation can be associated with very large variations indeed as regards the amount of torsion.

Many years ago I came to the conclusion also that a number of so-called lateral curvatures, especially in the lumbar region, have no lateral bend whatever, but are pure malrotations which simulate scoliosis; even skiagrams give this erroneous impression. Also that the cause of these malrotations is in most cases traumatic, due to the subject making a sudden twisting movement of the trunk: this is transmitted down the lumbar spine and is suddenly arrested by the inertia of the pelvis; a malrotation results between the fifth lumbar vertebra and the sacrum, and thus a starting point for the arising of so-called scoliosis is set up. I have already embodied these points in detail in several papers.[2]

There is one point of paramount importance in connexion with the part played by rotations in the etiology of scoliosis on which Mr. McCrae Aitken does not touch. It is this: all malrotations are minor displacements, and most minor displacements can be replaced quite quickly, easily, and painlessly if one possesses the necessary technique; this I should mention takes many months, not to say years, to acquire. I have now replaced several thousands of malrotated vertebrae occurring in so-called scolioses, and have thereby obtained the most gratifying results. As I wrote in 1923:

"In a large number only one single application of treatment, consisting exclusively of preliminary manipulations to cause relaxation of the muscles surrounding the displacement, followed by reposition of the latter, has been completely successful; in others two such applications have been all that has been required. . . . In the event of the muscles surrounding the displacement not being contracted, the treatment can be limited to effecting reposition and thus enable many cases of commencing scoliosis to be cured in half a minute or less."

Since writing that I have had no reason to modify my views.—I am, etc.,

41, Welbeck Street, W.1, Dec. 9th. EDGAR CYRIAX, M.D.Ed.

GIDEON MANTELL'S SPINE.

SIR,—In the leading article on the treatment of scoliosis (November 23rd, p. 969) are two references to Gideon Mantell which puzzle me. He is described as a "celebrated Egyptologist," but although he opened many barrows on the Sussex Downs I know of no evidence that he extended his archaeological investigations so far as Egypt.

It is further stated that the very peculiar condition of his spine "was first correctly diagnosed by Adams, whose diagnosis was confirmed at necropsy." I have been unable to find any evidence that Adams saw the patient before death. Mantell in his will left a sum of ten pounds to Dr. Thomas Hodgkin of Bedford Square, for a post-mortem examination of his body, and instructed his executor that this should be restricted to the spine and right elbow, "in the belief that the abnormal changes which have taken place may be interesting in a pathological point of view; if any parts are worth preserving for examples of morbid changes, let them be sent to the Hunterian collections." Dr. Hodgkin seems to have called upon his young colleague Mr. William Adams, demonstrator of morbid anatomy at St. Thomas's Hospital, to carry out the necropsy. This enabled the latter to discover the actual condition of "rotation" of vertebrae which had baffled all previous attempts at diagnosis. W. Adams at the time considered it to be unique, but learned afterwards that Dr. Dods of Bath, in 1824 (twenty-eight years previously), published *Pathological Observations on the Rotated or Contorted Spine, Commonly Called Lateral Curvature.*

A photograph of Mantell's spine in the Hunterian Museum is reproduced in my account of his life.—I am, etc.,

Lewes, Dec. 10th SIDNEY SPOKES.

*** We much regret that Gideon Mantell's twisted spine should have led us into deviations from the straight road of fact.

[1] *British Medical Journal*, 1924, ii, p. 558.

THE BURDEN OF DEAFNESS.

SIR,—I regret that, owing to absence from home, I have not had an opportunity of seeing whether anyone has taken up the cudgels on behalf of the deaf in reply to Mr. Mortimer Wharry's letter in your issue of November 2nd (p. 832). Perhaps you will allow me, as one of the partially deaf, to answer it even at this late date.

I write from the point of view of one who at times is able to hear any individual who speaks clearly to me in an almost normal voice, and at other times can only hear with a speaking tube. As such, I would like to assure Mr. Wharry that it is not as a rule "self-consciousness" which prevents those who derive no benefit from the many electrical appliances for the deaf from using a tube. The usual *reasons* are the embarrassment of those who are asked to use the tube for speaking to the deaf person, and the impossibility of finding one person in fifty who will use it intelligently. There are many who shout down it as they would if there were no tube, others begin correctly and then repeatedly turn away the head in the middle of a sentence. There are yet others (and amongst them I have known a surgeon) who habitually gesticulate with the free end of the tube!

In the course of my work in a hospital I come across a fair number of deaf people. Occasionally, when I speak loudly to one who is obviously very deaf, I am met by the dull, hopeless look of the incurably deaf. Then I introduce a speaking tube, which I always keep handy, and the joy of hearing the natural voice, sometimes it may be for the first time for many years, is such that I am prompted to give them a tube; but though, with a few, it proves a permanent boon, the majority find "they cannot hear their friends with it."

If the deaf are "self-conscious," are they entirely to blame? Are the blind ridiculed in our theatres, our comic papers, our books, and in conversation? How is it with the deaf? Mr. Mortimer Wharry says that he is not lacking in sympathy; does he know what it means to be constantly misunderstanding and saying and doing the wrong thing? The good Christian will laugh with those who laugh at his mistakes or regard him as half-witted, but sometimes one needs to be a *very* "good Christian" if one is not to be self-conscious.

Lastly, Mr. Mortimer Wharry offers us two pieces of consolation: (1) ". . . deaf people have some advantages which are denied to others; they need not hear if they would rather not, and in a world confronted with the problem of increasing noise this is a blessing." (2) "Furthermore, their very gesture of handing the mouthpiece of a speaking tube to an acquaintance is a request to say something worth hearing." With regard to the first, has he never seen a person popularly described as "born deaf and dumb" start and look pained at a shout or other loud noise? I have, and can sympathize, for I know that loud noises can, if anything, be more painful to many deaf people than to those with normal hearing. With regard to the second crumb of comfort, we know that Mr. Wharry is sympathetic, but has he a sense of humour?—I am, etc.,

Woburn Abbey, Dec. 8th. M. BEDFORD.

SIR,—The National Institute for the Deaf frequently becomes aware of instances in which medical men have advised persons, becoming deaf, not to practise lip-reading on the ground that it will induce them not to use their remaining hearing power fully in the effort to listen. Such advice is opposed to fact, since the visual observations of speech (lip-reading), running *pari passu* with whatever may be heard of it, give focus to the effort of listening, and make it easier and more effective and therefore more likely to be attempted.

In most cases deafness is progressive. If lip-reading is practised in the early stages the patient almost imperceptibly grows to its full and easy use. He is then forearmed against devastating isolation when he can no longer hear. Meantime, he has escaped much that would probably have saddened and discouraged him. He has been more in touch with life than otherwise he would have been. His misunderstandings and disappointments have been fewer. He has not realized his infirmity so

poignantly as he might have done. Life has been brighter and better. These are great advantages worthy of serious consideration by those who advise the deaf.

Completely deaf persons, taking up the study of lip-reading for the first time, are often unnecessarily alarmed by what they wrongly regard as the immensity of the task. By this time they are frequently depressed, nervous, and fearful of effort. Only those strong enough to overcome these handicaps are likely to succeed.

Lip-reading is the most promising remedy for the relief of the social ills of deafness; but, as is the case with every other remedy for human suffering, it should be applied at the right time. That time is at the early stage of the affliction.—I am, etc.,

A. J. STORY,
Secretary.

National Institute for the Deaf,
2, Bloomsbury Street, W.C.1, Dec. 16th.

CREMATION IN GUERNSEY.

SIR,—A crematorium has just been opened in Guernsey by the States, or Government, of the island. The mortuary chapel of the Foulon cemetery has been enlarged for the purpose. The coke furnace has been supplied by Gibbons Brothers, Ltd., of Dudley, and provision is made for a second furnace should circumstances require it in the future. On account of the elevated position of the chapel it has been found to be very efficient, and to heat quickly. A columbarium and "garden of remembrance" have been provided. The beauty of the site, and the way in which the work has been carried out by Mr. T. J. Guilbert, the States surveyor, gave great satisfaction to both official visitors and inhabitants.

The local law, although somewhat on the lines of the English one, has some important modifications, perhaps improvements. Certificates "A" and "B" are identical with it, and so is the wording of "C," but it has to be filled in by the medical referee, who is the States medical officer of health (a whole-time official), or his deputy, instead of a second medical practitioner. Certificate "F," which in England has to be signed by the medical referee, and is the authority to cremate, has to be signed by one of the law officers of the Crown—the Attorney-General or Solicitor-General. These officials have the power to refuse to allow the cremation without stating any reason. If a post-mortem examination is officially ordered, two medical practitioners must be present and supply a joint report, one being the medical referee, the other being appointed by the Crown law officers. At every judicial necropsy in Guernsey two medical men must be present; their fees are paid by the Crown. In the event of a dead body being brought into Guernsey for cremation, Form "A" must be countersigned by a person having authority to administer an oath in the place from which the body came; "B" "C," and "D" must be filled in and properly attested, which means that a necropsy by two doctors must have been made.

The Burial Law of Guernsey is stringent, in that no corpse can be buried except in a burial ground approved by the Royal Court. It is also forbidden to dispose of a corpse except by burial or cremation as regulated by the Ordonnance, without the consent of the Royal Court, who will impose such restrictions as they may consider necessary. If permission were granted, for example, for burial at sea, the formalities required by the Cremation Law would, no doubt, have to be first observed. As regards an exhumation, if the body has been buried in consecrated ground, and it is desired to re-inter it in consecrated ground, the Ecclesiastical Court of the island, which still has great authority, gives the permit if it thinks fit to do so. In other cases the Royal Court of Guernsey would be the authority concerned.—I am, etc.,

HY. DRAPER BISHOP,
States Medical Officer of Health.

Guernsey, Dec. 5th.

GAS-OXYGEN ANAESTHESIA.

SIR,—With reference to the interesting article by Mr. Edmund Boyle regarding gas-oxygen anaesthesia in midwifery (December 7th, p. 1051), I have used this method a limited number of times during the last three years, and have nothing but praise for it. I was particularly struck by some of the points he mentions—namely, that analgesia can be produced at will, often when requested by the patient, and that it need not interfere with the uterine contractions, and has little or no after-effects. In my experience, admittedly small, gas-oxygen is far superior to chloroform in these cases. It has, however, as Mr. Boyle says, the disadvantages of being expensive and requiring special knowledge in administration.—I am, etc.,

E. MOXON BROWNE,
Surgeon Commander R.N.; late Anaesthetist R.N. Hospital, Malta; and Honorary Anaesthetist, King George V Hospital, Malta.

H.M.S. *Malaya*,
Devonport, Dec. 9th.

Obituary.

THE death took place at his residence, Abbey Green, Jedburgh, on November 23rd, of Dr. WILLIAM BLAIR, a well-known practitioner of the Border district. Dr. Blair was born in 1838, and was thus in his ninety-second year. After studying at Glasgow University, he graduated M.D. there in 1863, and afterwards acted as assistant in the Lying-in Hospital of that city. Taking up practice in Jedburgh shortly before 1870, he spent a busy life of over fifty years in the practice of the medical profession in that town and its neighbourhood. He took a great interest in local public affairs, held several friendly society appointments, and was a staunch supporter of the British Medical Association for many years. One of his principal hobbies was photography, and having taken up the study of colour photography soon after its introduction, he had become a recognized expert in this subject. Dr. Blair was a widower, and is survived by two daughters.

Dr. WILLIAM HENRY FRETZ, who was accidentally killed near his residence in Parkstone, Dorset, on November 26th, was born in Ceylon, in 1859. He was the son of an official in the Ceylon Civil Service, and was directly descended from an old Dutch family, who went to that island in the seventeenth century. He received his medical education in Aberdeen, and obtained the diplomas L.R.C.S., L.R.C.P.Ed. in 1880. After practising for a short time in England he obtained a Government appointment in the island of Nevis, British West Indies; he was subsequently appointed to St. Kitts, where he became senior medical officer of the Presidency. He was a member of the executive and legislative councils and, on occasions, was responsible for the government of the colony in the absence of the administrator. Dr. Fretz retired in 1920, after having served for thirty-nine years. He was an active member of the British Medical Association, and at the time of his death was a member of the Bournemouth Division. He leaves a widow and three sons.

Dr. GEORGE CLARK STEWART, who died at his residence in Falkirk, on November 29th, at the age of 60, received his medical education at Glasgow, where he graduated M.B., C.M. in 1891, with high commendation. For a few years subsequently he practised at Stratford-on-Avon, and then went to Falkirk thirty years ago to take over the practice of the late Dr. Allan. Dr. Stewart was medical referee to the East Stirlingshire Pensions Committee and the Employment Department of the Ministry of Labour; he was also medical officer to the Falkirk and District Ironfounders Accident Insurance Company. During the war he held a temporary commission in the Royal Army Medical Corps, being stationed first at Ashton-under-Lyne, and subsequently serving in the Auxiliary Hospital in Falkirk. He was a member of the British Medical Association.

The following well-known foreign medical men have recently died: Professor THEODOR SOMMERFELD of Berlin, an authority on industrial hygiene, aged 69; Dr. ALEXANDER SKUTETZKY, lecturer on medical pathology and treatment at the German University of Prague, aged 61; Dr. PAUL FAIVRE, honorary inspector-general of the French Ministry of the Interior and Commander of the Legion of Honour; and Dr. PAUL SOULIGOUX, honorary surgeon of the French hospitals.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

In the House of Commons this week the Coal Mines Bill was the principal business. Debates were also arranged on unemployment and on a Supplementary Estimate for health administration in Scotland. The House has been asked to sit in Christmas week to debate foreign affairs. It will resume on January 21st, 1930.

In the House of Lords, on December 10th, the Highlands and Islands (Medical Service) Additional Grant Bill was brought up from the Commons and read a first time.

Mental Treatment Bill.

COMMITTEE STAGE IN THE LORDS.

The Mental Treatment Bill was considered in committee of the House of Lords on December 10th. A number of amendments were made, and the bill passed through committee. EARL RUSSELL stated that he hoped to take the report stage on December 17th. (The text of the bill was printed in the *Supplement* to the *British Medical Journal* of December 7th.)

Voluntary Boarders.

Clause 1 (power to receive voluntary boarders) provides that any person suffering from mental disorder who is desirous of voluntarily submitting himself to treatment and makes written application, may be received in an institution as a voluntary boarder without a reception order. Lord SANDHURST moved an amendment to omit the words "suffering from mental disorder," in order to make it as easy as possible for persons suffering from incipient symptoms to become voluntary boarders. He said it should not be necessary for a person to be so far gone in the disorder as the words in the clause implied before submitting himself to treatment. Under the corresponding section of the Lunacy Act, 1890, there was no definition of the voluntary boarder. All that was there necessary was that a person should be desirous of voluntarily submitting himself to treatment. Earl RUSSELL accepted the amendment in a slightly altered form, and it was agreed to, the clause then reading "any person who is desirous of voluntarily submitting himself to treatment for *mental* disorder," etc.

Viscount BRENTFORD moved an amendment to alter from 18 to 21 the age at which any unmarried person suffering from mental disorder, whose parent or guardian was desirous of submitting him to treatment, might, if the parent or guardian made written application, be received as a voluntary boarder. He said it was questionable whether a person of 18 years should be allowed in any circumstances voluntarily to place himself or herself in a mental home. Earl RUSSELL explained that the age of 18 was adopted from an amendment which the House inserted in the Mental Treatment Bill of 1923. He suggested that Lord Brentford should agree to a later amendment by Lord Danesfort, the purpose of which was to accompany the consent by a medical certificate. The amendment was accordingly withdrawn.

The Earl of CRANBROOK moved an amendment to provide that where an unmarried person was not under 16 his consent to the application by the parent or guardian should be given in writing. He said he was moving the amendment on behalf of the London County Council, which had many mental institutions and large experience in dealing with people suffering from mental disorder. The council felt that the age of 18 was too high for the parent to have sole control over a practically grown-up man or woman. Earl RUSSELL replied that it was better not to accept the amendment in view of the one to which he had alluded, which would reinforce the judgement of the parent or guardian by a recommendation by a doctor. The Government proposed to use the word "recommendation" rather than "certificate." They wished to avoid the use of the word "certificate." The Earl of CRANBROOK pointed out that persons of 16 were able to marry, which was a much graver step than going for treatment in a mental hospital. Lord DAWSON said that if they were dealing with people of normal mind he would give his support entirely to the young person having the *right of decision*, but unfortunately nature had decided this matter. Mental disorders, which might easily develop into insanity *properly so-called*, were prone to arise at the ages of 16 or 18. The existence of these mental disorders, slight though they *might* be at that stage, made these young people "difficult." Sometimes it was almost impossible to get them better *in their own homes*. They were, in a sense, antisocial, and therefore did require rather more pressure than those who were normal. Young people with these incipient disorders were to be looked upon as being younger than the normal by two years. If Parliament supported the application of the parents by a medical certificate or medical recommendation—which, he agreed, was a better term—they would safeguard the bill against abuse, as they all desired to do.

Viscount BRENTFORD said that the whole tenor of Lord Dawson's speech made him anxious about the clause. The clause related to the voluntary right of a person to shut himself up. It was not a question of pressure. Under the clause the voluntary judgement of this so-called voluntary patient was to be taken away, and pressure was to be put on him by the parent and the doctor who was prepared to sign the recommendation. Lord BANBURY said he agreed with Lord Dawson that the clause was not a voluntary one, but one which might lead to pressure. The amendment was withdrawn.

Lord DANESFORT moved an amendment to ensure that a young person under 18 might be received as a voluntary boarder only if *the written application of the parent or guardian* were accompanied by a medical recommendation. He said he understood that the Government were prepared to accept the amendment. It was possible that in some cases there might be parents or guardians who would like to lock up a child who might be a little unruly or disagreeable, *and in the interests of the liberty of the subject* it was desirable to have some further protection in the bill. Lord Dawson and others had suggested that this incarceration of a young person should not take place unless there was a medical certificate or recommendation saying that it was desirable for him to be so detained.

Earl RUSSELL said that if it was desired to afford an expression of will to persons between 16 and 18 he would consider the matter before the report stage. Viscount BRENTFORD expressed regret that a young person under 18 could be locked up in any form of home or asylum without judicial proceedings. Under the clause as it was *proposed to be amended*, a young person was to be locked up on the recommendation of one doctor without the *right*, which he had to-day, to go before some kind of judicial officer, even a magistrate. Lord MERRIVALE said it would be a grave invasion of the common law rights of His Majesty's subjects if, instead of the age of 16, which for generations had been known as the age of responsibility, they substituted an arbitrary age without any safeguard except the certificate of one medical man. Earl RUSSELL agreed that this was an invasion of the common law right of personal liberty, but it was recommended in the interests of the patient. The question of the consent of the person of 16 had not been met because the suggestion that he should consent before going in had not been before the Government until that moment. It followed naturally that if the patient over 16 had to consent to go in for this treatment he must continue to consent when he was there. That would be one of the matters which he would consider on the report stage. The amendment was agreed to.

Lord DANESFORT moved a new subsection, *providing that*—

"The medical recommendation referred to in the last subsection shall be signed by a registered medical practitioner, who shall be either the usual medical attendant of the person to whom the application relates, or a person who has been approved for the purpose of making a medical recommendation under this the last subsection either by the Board of Control or by the local authority within whose area the said person then is. Such recommendation shall state the qualifications of the medical practitioner, the date or dates on which he examined the said person, that the said person is likely to be benefited by being received as a voluntary boarder for treatment for mental disorder under this section."

Debate followed, and eventually Lord Danesfort said he would consider the matter before the report stage. He withdrew the amendment.

Clause 2 provides for notice of reception, death, or departure of voluntary boarders, and makes provisions for boarders who become incapable of volition. The third paragraph of the clause provided that if any person received as a voluntary boarder became at any time incapable of volition, he should not be retained as a voluntary boarder for longer than one month, but should, on or before the expiration of that period, be discharged, unless in the meantime he had again become capable of volition or steps had been taken to deal with him either under the principal Act as a person of unsound mind, or under this bill as a person incapable of volition who was likely to benefit by temporary treatment. Lord SANDHURST moved an amendment to provide that the medical superintendent or other person in charge of the institution should decide whether the voluntary boarder had become incapable of volition. He said that somebody should be made responsible for formulating the opinion on the patient's incapacity for volition. Earl RUSSELL accepted the amendment, which was agreed to.

Temporary Treatment Without Certification.

On Clause 5, which makes provision for treatment without certification of persons temporarily incapable of volition, Viscount BRENTFORD moved in Subsection (1) to leave out the words "on a written application duly made in accordance with the provisions of this section, but without a reception order." He desired to raise the question whether these patients who were suffering from mental disorder and were incapable of volition, but likely to benefit by temporary treatment, might be shut up on the decision or certificate of two doctors without judicial authority. The Royal Commission did not take the view which the Government had adopted, and his (Lord Brentford's) amendment embodied the proposal of the Commission. To save expense he

proposed that instead of two doctors there should be only one, but that there should be a magistrate, who should see the patient and his friends if necessary and decide whether it was really desirable in the interests of the patient that his liberty should be taken away. Up to the present Parliament had never allowed that liberty to be interfered with by any advisers except under judicial authority. Lord Brentford said that if the form of judicial authority proposed was objected to he would assent to any form which met with the approval of Lord Russell. A very great alienist had said that the number of wives who came to ask him to certify their husbands was only equalled by the number of husbands who came to ask him to certify their wives. The friend and adviser of the incipient patient should be a judicial authority who was quite independent of those who desired to place the patient under control. The question had nothing to do with the skilled opinions of medical men as against those of the law; it was whether there should be any person unconnected with the patient, unconnected with the medical adviser, to consider if the patient should be locked up or not.

Earl RUSSELL said that neither he nor the Minister of Health had any objection to a judicial authority in itself. The objection unfortunately came from the patient and his relatives. It was true that a judicial authority was recommended by the Royal Commission with reluctance, but it was much better for the patient that the matter should be done in a less formal way. They wanted, under this bill, to treat incipient mental disorder without the stigma of certification. He begged Lord Brentford not to talk about persons being "locked up" and being "put away." Those were the expressions which it was desired to get out of the mind of these patients. They wanted to talk to them about being treated for their health, and to assimilate the treatment as far as possible to the treatment for ordinary illness. Detention might be a necessary part, but it was not the part on which they desired to insist. Could the House suppose that if two competent medical men signed a certificate, giving perfectly clear facts on which they based their conclusion, that a justice would take upon himself in the ordinary way to override that certificate. The most he could do would be to see that everything was regularly done. That was the duty both of the superintendent of the institution to which the patient was taken and of the Board of Control who received the certificate. These were much more competent to perform that duty than the ordinary justice.

Lord DARLING said that Mr. Hugh Macmillan, K.C., who was the chairman of the Royal Commission, was of opinion that what was proposed in the bill was the proper way of dealing with these incipient mental cases. Intervention of justices of the peace would be bad for the patient.

The Earl of ONSLOW suggested that it might be possible to entrust the endorsement of the recommendation of the two medical men to the Commissioner or the Assistant Commissioner of the Board of Control, or at any rate to the authority of that Board rather than to a judicial authority.

Lord MERRIVALE hoped that Lord Russell would consider Lord Onslow's suggestion. In 999 cases out of 1,000 it was desirable that these people should be under treatment, but everyone knew that the odd case occurred, whether through interest or malice or some indirect motive, and produced mischief. The present procedure was really not a safeguard. For a delicate matter of this kind he thought they might have a body of referees nominated in the public interest. There should be a panel of qualified persons in whom medical men and everyone else would have confidence.

Lord HANWORTH said he hoped that the Government would hold to the bill. The same reluctance would be shown to go before a board of referees as to go before a magistrate. The stigma was really the same, and such a step would interfere with the recovery of these patients. So long as the matter was left in the hands of the medical man, and treatment was given by the medical man, there was some hope for them.

The Marquess of SALISBURY said the matter was not a purely medical one. He asked if Lord Russell had considered the difficulty of determining what the actual volition of the patient was, and whether he had exercised it.

Earl RUSSELL said that he did not think that the difficulty would arise in practice. The person was not necessarily comatose —confusional was rather the word. A great many of the confusional cases were so excited and upset by the procedure of certification and by seeing a justice that it often put them back as much as six weeks before they began to make progress in the quiet surroundings of the asylum.

Viscount CECIL OF CHELWOOD suggested that a way out of the difficulty might be to insist that one of the two medical practitioners who were to sign the recommendation for temporary treatment should be a person who had been proposed for the purpose by the Board of Control.

Earl RUSSELL said that that was a valuable suggestion, and he would certainly consider it before the report stage.

Lord DAWSON OF PENN said that the medical profession had no objection to safeguards, provided they were such as would not prejudice the cure of the patients who were ill. They frankly admitted that those patients with which the bill dealt constituted a class that had not hitherto been dealt with by the Legislature. They were people for the most part living in small houses and earning small incomes. The difficulties were much less among the well-to-do. They had large houses, where persons mentally sick might perhaps have two nurses, and where the treatment could be carried out quite easily. The class of patient to which the bill referred was a class that was grievously suffering, or had very little or no opportunity of being relieved. Let them take the case of an out-patient at a hospital who might have influenza or some simple illness. He went there with a feeling of depression, under a power of self-criticism, subject to introspection, and might go step by step down to that absolute suffering which they all knew, and for which they were perfectly powerless to do anything under present conditions. If they wanted to do anything with such patients now they had to be certified. That brought him to the question of certification. The word "certification" conveyed notions of a madman and all the things that had been from generation to generation associated with that name. He admitted that many of the fears entertained were unreasonable, but they were there, and the medical profession, which had to do with the sick, constantly found those difficulties arising. It had to be borne in mind that the patient whom they hoped to help by this bill was very often a sensitive, very impressionable, and sometimes very competent person—someone who was cut a little bit too fine for the environment in which the world had placed him. The nervous system of those people was very easily wounded. They were a class which was increasing with the civilization which we had to-day. They might be very competent in their work, and were very often efficient and capable of being leaders. Doctors had often come across them in the war. Such people might get some toxic condition arising from influenza; or, in the case of a woman, it might be due to childbirth. Under the stress or strain of that, or because of overwork, they would begin the down grade, with which doctors were familiar. They would have a want of confidence, would indulge in self-criticism and self-abasement, and might in the end become insane. No class had to be more carefully handled by medical men or required a greater intuitive insight, tenderness, and sympathy. One false word, and the doctor's influence vanished. Very often one had carried the patients along and convinced them that all their distresses, their sleeplessness, that burden of life which had become a horror to them, was due to overwork, and that by proper treatment they would get better. Then, suddenly, the patients would turn to one and say, "Do you think I am going to lose my reason?" They were so quick in feeling that. Supposing that the patients had reached the stage where one had to put them under treatment, and that at that time one introduced anything like certification—anything that had an association with certification—one got not only their friends, but people who knew them, the social circle in which they moved, entertaining certain feelings towards them. It was a fact that certification was associated with a very grim past. Anything that interfered with the secrecy and the confidential relationship of medical advice was to be avoided, and that was why it was so important that the provisions of this bill should be carried out. They could have precautions if they liked, provided these did not become so cumbersome as to render the measure nugatory. There might be precautions, provided they were careful precautions that would not in any way damage the good effect of these provisions. If these patients once realized that they were thought to be insane they would have been given for the rest of their lives a sense of inferiority. They would constantly say: "I am damaged; I have been insane; I have been locked up." They got the thought that they had done an injustice to their children, and they knew that it prejudiced the chances of the marriage of their children. Their lordships knew how very anxious people were if there was any question of insanity in the family. For those reasons he wished to emphasize the benefits of the bill. The bill would enable the poorer classes to get at any rate some of the benefits now open to the more prosperous and happy classes. Further, it would do what the medical profession and those who had thought upon this matter desired—it would bring about the prevention of insanity. The bill did not deal with insanity, and therefore they asked that it should be kept away from all mention of the machinery of insanity. Its whole object—and he was quite confident that it would be successful in this—was to take these people when they were suffering from mental illness just as one took them when suffering from physical illness, and treat each one according to his need and in the same way as in the case of physical illness. If that were carried out with any precautions that were suitable, provided they did not run counter to the feelings of the people whom they desired to help, he was confident the bill would be of great good to the community. Viscount BRENTFORD said that he would withdraw his amendment and ask the Government to consider the various proposals which had been made to get over the difficulty with regard to the rights of the liberty of the subject. Their object was, as Lord

DAWSON had said, to give every possible security without doing harm to the patient. Earl RUSSELL said that he would be glad to consult with Lord Brentford. The amendment was withdrawn.

An amendment by Lord SANDHURST, to enable the Board of Control to extend the time under which a non-volitional patient would be able to receive treatment to a period not exceeding three months beyond the six months provided in the bill, was agreed to.

Reorganization of Board of Control.

On Clause 11 the Earl of ONSLOW moved an amendment providing that the Board of Control should consist of the chairman and not more than five other Commissioners (instead of four, as provided in the bill). He urged that there should be two medical Commissioners, as they required very urgently that a medical man, with the full authority of the Board, should be available at any moment at the Board of Control. If there was only one medical Commissioner it might be difficult, in the case of his illness, to have his advice and authority. Earl RUSSELL said that he could accept the two medical Commissioners, but not the total of five members in addition to the chairman. The Earl of ONSLOW said that if Earl Russell would tell him that there would always be a medical man, with full authority, that would go a long way to meet the difficulty. Earl RUSSELL said that there was, of course, the possibility of the woman member being a medical person. The Government were very reluctant to increase the number on the Board to five. If Lord Onslow asked if any medical Commissioner would be available under the Assistant Commissioner that would certainly be so. This person would have all the administrative powers, to be exercised in case of emergency, except that of sitting on the Board. The Earl of ONSLOW said that would meet his point, and withdrew the amendment.

Lord SANDHURST had tabled an amendment to Clause 16, to ensure that no civil or criminal proceedings should lie against a person who had signed or carried out a reception order or any other report or certificate under the bill, unless he had acted negligently and without reasonable and probable cause, the question of reasonable or probable cause to be determined by the judge. This safeguard was drafted by Lord Sandhurst as an amendment to the provision in the bill that such a person should not be liable to civil or criminal proceedings unless he had acted in bad faith or without reasonable care. Lord Sandhurst, however, did not move this amendment, and the clause passed without discussion.

An amendment by Viscount BRENTFORD, providing that the rules made under the bill should be subject to the sanction of Parliament, was agreed to.

Vaccination.

On December 12th Mr. FREEMAN asked if Mr. Greenwood could announce any concessions in respect of the Vaccination Acts. Mr. GREENWOOD said he was considering the whole subject of vaccination, including the desirability of further inquiry, but could not then make any announcement. The latest figures available, those for 1927, had shown that in that year just over 40 per cent. of the parents made declarations of conscientious objection to vaccination. Mr. FREEMAN asked if the Minister would consider placing vaccination on a voluntary basis. Mr. GREENWOOD said that would be a matter for examination.

Answering a further question from Mr. Richard Russell on the same date, Mr. GREENWOOD said that the Ministry of Health had information of 100 deaths from encephalitis following vaccination from December, 1922, to September 30th, 1929. As a result of recommendations, published by an expert committee last year, some modifications had been made in the technique which public vaccinators were advised to follow.

Mr. GROVES asked whether Section 8 of the Vaccination Act contemplated revaccination by public vaccinators only where persons applied for it, and why the new regulations issued by the Minister authorized revaccination of children as young as 12 months. Mr. GREENWOOD, replying, said nothing in the Vaccination Order, 1929, conflicted with Section 8 of the Vaccination Act, 1867. In the case of a child, application had to be made by the parent or other person having its custody.

In a reply to Mr. Freeman Mr. GREENWOOD said 35 cases of smallpox occurred in England and Wales as a result of the outbreak of the disease in the ship *Tuscania* last March. Of these, 21 cases were vaccinated, 6 revaccinated, and 6 unvaccinated. The vaccinal condition of one was doubtful, and of one unknown. Of the vaccinated cases, all but two were persons of 19 and upwards who had been vaccinated only in infancy. Among these 35 cases, eleven deaths occurred—three of the 6 unvaccinated cases, seven of the 21 vaccinated cases, and one case in which the vaccinal condition was unknown proving fatal. There were no deaths among persons known to have been revaccinated. He furnished a table showing the districts in which the cases occurred, the ages, and the vaccinal condition.

Care of Mental Defectives.—Mr. GREENWOOD stated, on December 12th, that 28 local authorities in England and Wales had provided institutions for the residential care of mental defectives; 18 had schemes in progress, but 78 had not then made any institutional provision.

Hospitals Supported or Aided by Local Authorities.—Mr. GREENWOOD told Mr. Thos. Griffiths, on December 12th, that one large general hospital with 875 beds and three relatively small accident hospitals had been provided by local authorities in England and Wales. In 1927–28, local authorities subscribed £25,000 in donations to voluntary hospitals under the Public Health Act, 1925, and boards of guardians contributed £44,000 to public hospitals. In the same period local authorities provided 166 hospitals for tuberculosis, with 12,787 beds, and 287 hospitals for acute infectious diseases, with 36,833 beds, of which 2,205 beds were for tuberculosis. They also provided 79 maternity hospitals, with 1,631 beds—not including maternity wards in general hospitals or Poor Law institutions—and 11 babies' hospitals, with 253 beds. Voluntary hospitals aided by local authorities included 138 tuberculosis hospitals, with 9,202 beds, 164 general hospitals used in tuberculosis schemes, 130 used in venereal disease schemes, and 22 hospitals used in maternity and child welfare schemes; also 65 maternity hospitals, with 1,323 beds, and 12 babies' hospitals, with 347 beds. In grants to general voluntary hospitals and tuberculosis voluntary hospitals in 1927–28, local authorities in England and Wales expended £825,000, and for maternity and child welfare hospitals £78,000.

Doctors and Trade Unions.—Dr. VERNON DAVIES, speaking on December 6th, during the debate on the Industrial and Provident Societies (Amendment) Bill, said doctors had no trade union. They would have much greater power if they possessed one. There was not a single medical man in the House who was subsidized or paid or helped by the medical profession. Could that be said of miners or co-operators?

Mental Nurses and Registration.—Miss LAWRENCE, on December 10th, told Mr. Remer that the Minister of Health was not empowered to issue any Order to ensure that mental nurses who possessed the Royal Medico-Psychological Association's certificates received admission to the register kept under the Nurses Registration Act, 1919.

Emission of Smoke from Buildings.—On December 10th Mr. GREENWOOD told Mr. Somerville Hastings that a model by-law had been issued to assist local authorities in regulating the emission of smoke from buildings. Seventy-three local authorities had made by-laws under this section.

Navy, Army, and Air Force Insurance Fund.—In an answer to Sir Kingsley Wood, on December 12th, Mr. GREENWOOD stated that if members of the Navy, Army, and Air Force Insurance Fund continued their membership after discharge from the forces they were entitled to increases on the normal rates by 4s. a week sickness benefit, 2s. a week disablement benefit, and 8s. maternity benefit, besides payment of the whole cost of dental treatment, ophthalmic treatment, and the provision of dentures, spectacles, and medical and surgical appliances.

Graduates Holding Indian Medical Degrees.—Major GRAHAM POLE asked Mr. Wedgwood Benn, on December 12th, whether he had been notified by the General Medical Council as to its decision in respect of the position in this country of graduates holding Indian medical degrees. Mr. WEDGWOOD BENN replied that, as matters stood, the recognition of Indian medical degrees was governed by the resolution of the General Medical Council of July 22nd last. There had been no later decision by the General Medical Council, but he understood that the situation which had since arisen would be considered by the Executive Committee at its next meeting in February.

Position of Medical Officers of Local Authorities.—Dr. VERNON DAVIES asked Mr. Greenwood, on December 12th, if he had considered, in relation to the recommendations of the Royal Commission on Local Government, the case of medical officers of local authorities, such as a public vaccinator, a district medical officer under the guardians, and a medical officer of health to an urban or rural district council; and whether he would issue a statement to local authorities on the position of such officers in respect of membership of local authorities. Mr. GREENWOOD said the recommendations of the Commission were under his consideration, and he did not think a special statement to local authorities on the matter was required at present.

Asbestosis.—Mr. THORNE asked the Home Secretary, on December 12th, if his attention had been drawn to an inquest held at Ilford on an employee of an asbestos firm at Barking who died from asbestos poisoning; if he was aware that asbestosis was prevalent in asbestos factories, especially at Barking; and whether he was prepared to schedule this disease under the Dangerous Diseases Act. Mr. CLYNES said he had received a report from the Factory Department on this case. A medical inspector of factories had recently made a comprehensive investigation into the occurrence of this disease among asbestos workers generally. Mr. Clynes said he was considering the report of this inspector, both as regards the preventive measures to be taken and the question of bringing the disease under the Workmen's Compensation Act. The investigation did not disclose any special incidence of the disease at the Barking works. There the exhaust ventilation, which was the chief means of prevention, was quite up to the usual standard and was being constantly improved.

Notes in Brief.

Under the Widows and Old Age Pensions Act, 1929, about 10,000 persons in lunatic asylums or Poor Law infirmaries will cease to be disqualified from receiving pensions.

In 1928 the infant mortality rate for the borough of West Ham was 49 per 1,000, for North Kensington 93, and for the Norland ward of the borough of Kensington 115.

The Preservatives Regulations of the Ministry of Health prohibit the importation of fruit, other than dried fruit, which is preserved with sulphur dioxide, unless it is intended for conversion into jam or cured fruit.

During the twelve months ended September 30th, 1929, work was in progress on ninety-seven slum clearance schemes in England and Wales.

UNIVERSITY OF BIRMINGHAM.

THE following candidates have been approved at the examinations indicated:

M.D.—J. W. Field (with honours), C. J. Polson.
M.B., Ch.B.—T. A. Cooper, G. J. Garratt, I. B. Gumede, R. H. Hucknall, E. J. Kerr, D. J. Mann, P. H. Methu, A. Monib, J. D. W. Shedden, Mary A. Tomlinson.

UNIVERSITY OF DURHAM.

ON the nomination of the Senate, Sir Thomas Oliver, M.D., LL.D., has been appointed Pro-Vice-Chancellor of the University.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

AT the earlier winter commencements, held on December 8th, the following medical degrees and licence were conferred:

M.D.—R. W. T. H. Stewart.
M.Ch.—J. C. Fouché.
M.B., B.Ch., B.A.O.—G. R. Beare, Josephine M. Enright, G. C. Graham, W. B. Hamilton, W. R. Johnston, W. A. Y. Knight, J. F. K. MacCarthy-Mortogh, F. S. Mackenna, J. N. U. Russell, Lilla M. Spiller, A. B. Thrift, Frances E. Wilson, E. J. M. Bam, A. G. Garde.
LIC.MED. AND S.—M. E. Kirwan.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Council of the Royal College of Surgeons was held on December 12th, when Lord Moynihan, the President, was in the chair.

The death, on November 17th, of Mr. T. H. Openshaw, past Member of the Council, was reported, and a vote of condolence was passed.

Fellowship.

The Fellowship of the College was conferred upon the following:

M. S. K. Joshi, R. M. Dannatt, D. L. Jones, G. J. Griffiths, E. F. King, J. L. Griffiths, A. J. King, N. E. Laurence, H. V. Wells, A. S. Gough, J. F. E. Gilham, H. L. Peake, F. W. Law, Beatrice G. Smith, J. McN. Milloy, J. G. Wigley, W. P. Greenwood, A. W. L. Row, E. McLellan, W. C. W. Nixon, R. E. Norrish, S. F. Russell, S. Shalaby, W. E. Underwood, P. Forte, M. Y. P. Peiris, W. J. H. M. Beattie, M. V. Modi, H. S. Waters, M. C. Rous, H. T. Simmons, P. Wiles, J. O. Smith, J. Dawson, D. N. Epstein, A. L. Johnston, A. J. Mason, A. R. Mowlem, L. A. Riddell, A. L. Webb, F. E. Webster.

Membership.

Diplomas of Membership were granted to E. Marks and Alison J. Rae.

Recognition of Hospitals for Final Fellowship Examination.

A recommendation from the Court of Examiners "that the Blackburn and East Lancashire Royal Infirmary and the Hampstead General and North-West London Hospital be recognized for the twelve months' surgical practice required of non-members before admission to the Final Fellowship Examination," was approved and adopted.

Appointments.

Lord Moynihan was elected the representative of the College on the Court of the University of Birmingham for three years from January 1st, 1930. Mr. C. H. Howkins of Birmingham was re-elected a member of the board of examiners in dental surgery, subject to the provisions of the Charters.

Demonstrations.

The President reported that Sir Frank Colyer had, upon the invitation of the Council, undertaken to give two demonstrations on the odontological collection on March 12th and 19th, 1930.

Annual Report.

A report from the committee on the annual report of the Council was read and the following reply to the resolution carried at the annual meeting on November 21st was approved and adopted: "No evidence has been submitted to the Council that the change in the constitution of the College advocated in the resolution is desired by any considerable number of Members of the College, and the Council is therefore not prepared to reopen the question at the present time."

Medical News.

THE House and Library of the Royal Society of Medicine will be closed from Monday, December 23rd, to Saturday, December 28th, both days inclusive.

A meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, January 14th, at 4 p.m., Dr. William Brown, Wilde reader in mental philosophy in the University of Oxford, will open a discussion on "The role of psychotherapy in the prevention and treatment of alcoholism and other drug addictions."

THE annual dinner of the Medico-Legal Society was held at the Holborn Restaurant on December 13th, with the president, Lord Riddell, in the chair. In proposing the toast of "Medicine and Law" Dr. Nathan Raw referred to the social revolution that had been brought about, directly or indirectly, by the work of such men as Harvey, Lister, Jenner, and Ross. It was difficult to believe, he said, that only a century ago two-thirds of the people of this country were disfigured by small-pox, a disease which, owing to Jenner's great discovery, had, in its severer forms, almost disappeared from England. The medical profession was proud of Lord Dawson and his team of skilled workers, who together had undoubtedly saved the life of the King. Medicine and the Law were united in supporting the Mental Treatment Bill now before Parliament, and their joint efforts would secure a greater advance than any that had hitherto been made in the treatment of persons suffering from early mental disorder. Lieut.-Colonel C. T. Samman, Master of the Society of Apothecaries, replying for Medicine, said that the doctor of the future would depend for his success not on mere empiricism, but to an increasing extent on the established sciences of biochemistry and bacteriology. He and the lawyer together would promote the public health by formulating and incorporating into the law of the land wise enactments designed to secure the prevention of disease. Replying for the Law, Mr. A. E. Mitchell-Innes, vice-chairman of the General Council of the Bar, said that sooner or later the joint wisdom of the medical and legal professions would bring about a change in the conception of what constituted insanity, and by their efforts the definition of insanity now acted on by His Majesty's judges would be brought into line with modern views on psychology. Lord Greenwood proposed the toast of "The Medico-Legal Society," and Lord Riddell, in responding, said that the value of the society to the lawyer and the doctor was that it provided them with an excellent resort in which they could spend "a business holiday." Replying to the toast of "The Guests," which had been proposed by Sir John Collie, the Attorney-General (Sir William Jowitt) referred to the criticisms which had lately been directed against the English system of coroners' inquests; he could imagine, he said, no greater tribute to the coroners of this country or to the system which they administered, than the fact that although about 30,000 inquests were held each year only one or two had been made the basis of adverse criticism. Mr. Donald Armour, also replying, said that the Medico-Legal Society could play a great part in the education of the two professions; the doctor had to learn to answer questions on matters about which he knew everything, and the lawyer to ask questions on matters about which he knew nothing.

AT a meeting of the Central Midwives Board for England and Wales, held on December 5th, a letter was read from the Ministry of Health stating that the existing rules of the Board were approved for a further period of one year, as from December 31st. Approval was given to a scheme of lectures to be delivered at Hull submitted by the medical officer of health.

THE Minister of Health received, on December 5th, a deputation from the Standing Joint Committee of Industrial Women's Organizations. The deputation was introduced by Dr. Marion Phillips, M.P. and the speakers drew attention to the acute

distress prevailing in South Wales, Durham, Northumberland, Staffordshire, and other necessitous areas, and stressed in particular the need for further financial help to enable boots and clothing to be provided for children. The deputation urged that further help was imperative and should be given through a public fund administered by public bodies. Distress should be the sole criterion for relief, and the areas to be assisted should not be fixed arbitrarily. The Minister said, in reply, that on the general question of relief to distressed areas there seemed to be some conflict of evidence. A full report had recently been obtained which appeared to show that the Lord Mayor's Fund was meeting the distress in the coalfields. The deputation had, however, suggested that that was not the case. Any further Government assistance was a matter upon which he would have to consult the Cabinet, and before he could submit any proposals he would require definite evidence that the Lord Mayor's Fund was not meeting the need. Dr. Phillips promised to submit further evidence, and pointed out that the need was not confined to areas in which the Lord Mayor's Fund operated, but was quite as great in some other necessitous districts. The Minister promised to give full consideration to that point.

AT the annual meeting of the British Dental Hospital, held in the Battersea Town Hall on December 5th, the president, Sir Harry Baldwin, made a presentation to Mr. George Thomson, L.D.S., who founded this institution in 1911. It was announced that the hospital now comprises five chief treatment centres, eight maternity and child welfare clinics, eight tuberculosis clinics, one insurance society clinic, one full-time school clinic, one special clinic for children under the age of 5, and also a centre for treatment of minor ailments and disorders of the ear, nose, and throat. The staff numbers two medical practitioners, thirty-nine dental surgeons, and twelve anaesthetists.

THE Joint Advisory Committee on River Pollution, which was appointed to "consider, and from time to time to report on, the position with regard to the pollution of rivers and streams, and on any legislative administration or other measures which appear to be desirable for reducing such pollution," met on December 12th and 13th at the Ministry of Health. The committee is at present addressing itself to the question of the access of trade and manufacturing waste liquids to the sewers of local authorities.

THE issue of *Schweizerische medizinische Wochenschrift* for November 30th is devoted to the proceedings of the thirteenth annual meeting of the Swiss Society of Dermatology and Venereology, held at Geneva on June 29th and 30th, under the presidency of Professor C. Du Bois.

THE Royal College of Physicians of London will be closed for the Christmas vacation from Tuesday, December 24th, to Monday, December 30th, both days inclusive.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*, telephone 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TRAIN SICKNESS.

"J. T. M." asks for advice in treating a healthy girl aged 9 years, who has attacks of nausea, culminating in vomiting, when she travels in a train, bus, or tram.

DIET AFTER JEJUNOSTOMY.

"A. J. A." asks for advice as regards the feeding of a man, aged 59, on whom a jejunostomy has been performed. Eleven years ago he was treated for duodenal ulcer by a posterior gastro-enterostomy; a large gastro-jejunal ulcer subsequently developed at the site of anastomosis, and, owing to the condition of the patient, the only possible operation was a jejunostomy below the site of the old anastomosis. The patient is now being fed through the new stoma with peptonized milk, butter, glucose, soups, and eggs (not peptonized); his digestion is good. Can any surgeon with experience of similar cases recommend anything else as regards food?

CHRONIC URTICARIA.

DR. H. S. BURNELL-JONES (London, N.W.) recommends "X. Y." (December 7th, p. 1093) to try autohaemotherapy for chronic urticaria of unknown causation. He writes: Withdraw 3 c.cm. of the patient's blood in a syringe and, without removing it from the syringe, inject it into the gluteal muscles. Gradually increase the volume of blood up to 10 c.cm., and give one injection every week.

DR. L. A. FRANCIS (Uxbridge) writes: A lady patient of mine was a sufferer from urticaria for many months, and was treated by diet and stomachics, by bromides and other nerve sedatives, by an autogenous vaccine, and by innumerable external remedies. She saw many physicians. Nothing did her any good till she took collosol calcium one teaspoonful in water thrice a day. She improved at once, and has remained well for several weeks.

LETTERS, NOTES, ETC.

COTARNINE HYDROCHLORIDE IN HAEMORRHAGE FROM THE PROSTATE.

DR. J. R. LOGAN (Liverpool) writes: I think it is worth while to put on record the very distinct success which I have had in the treatment of prostatic haemorrhage by the administration of cotarnine. If I remember aright the prostate is regarded as the anatomical homologue of the uterus, and therefore it was that I resolved to try whether the remarkable effect which cotarnine has in causing uterine contraction might be paralleled if I used it in treating cases suffering from haemorrhage from the prostate. In the past five or six years I have had the opportunity of trying the treatment on quite a dozen occasions and, I am pleased to be able to say, with phenomenal success. The bleeding always stopped in a few days, seldom persisting as long as a week. I have no doubt there are disorders of the gland in which this drug can be of but little, if any, use, but in simple cases I believe
[illegible] in checking bleeding, and also in
[illegible]ze of the prostate. I have ordered
[illegible]ain as a tabloid thrice daily.

TUBERCULOSIS AND THE ROYAL SOCIETY OF MEDICINE.

DR. G. GREGORY KAYNE (Denbigh, N. Wales) writes: It is hardly necessary to emphasize the benefits derived by the medical profession from the various Sections of the Royal Society of Medicine. Would it not be possible to organize a separate Section for tuberculosis? Tuberculosis takes an enormous toll in human death and illness, and well deserves special attention. Such a Section would bring together the men interested in the problem in its various aspects (for the disease still remains very much a problem), and perhaps prevent the periodical apathy into which the medical profession (as a whole) falls with regard to the disease. Moreover, the Society would attract many men who, occupied purely with tuberculosis, find it difficult to take an interest in a Society which hardly "caters" for them at present. It would be interesting to hear what other medical men specializing in tuberculosis think of this matter.

EXTRA-ARTICULAR FIXATION OF THE SACRO-ILIAC JOINT.

IN the abstract of the article on this subject by W. M. Phelps and M. K. Lindsay (*Epitome*, December 7th, para. 5091) it should have been mentioned that the procedure they employed was devised by Mr. P. Jenner Verrall, F.R.C.S., and published by him in the *Journal of Bone and Joint Surgery* in July, 1926. Messrs. Phelps and Lindsay in their article made it quite clear that they had been using Mr. Verrall's method.

THE CANCER PROBLEM.

IN the course of a letter Dr. A. W. CRAWFORD (Bolton) disagrees with the assertion of Dr. A. T. Brand on December 7th (p. 1094) that cancer has been demonstrated to be due to an extrinsic pathogenic micro-organism. He adds that the association of an organism with a lesion is no evidence of an etiological connexion, and that convincing proof of the microbic causation of spontaneous cancer is lacking.

PERCAIN.

WITH reference to the local anaesthetic percain, of which an account appeared on December 14th (p. 1114), we are now informed that it is not necessary to order supplies of it from the makers at Basle; it may be obtained from the Clayton Aniline Company, Ltd. (Pharmaceutical Department), 40, Southwark Street, London, S.E.1.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts not filled in the advertisement columns appears in the *Supplement* at page *268*.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

547. Hyperthyroidism as a Cause of Cardiac Disability.

D. K. BACON (*Minnesota Med.*, November, 1929, p. 659) remarks that the cardiac lesions resulting from hyperactivity of the thyroid gland are less characteristic than those due to the commoner causes, such as rheumatism, syphilis, and hypertension. He recalls the pathological findings of Goodall and Rogers, who detected, on microscopic examination of thyrotoxic hearts, an interstitial myocarditis, with evidence of hyaline degeneration and necrosis of muscle bundles; these observers also demonstrated electrocardiographic changes indicating myocardial damage. Regarding symptomatology, functional disturbances of the heart are very frequent as a result of thyroid disorders, and may occur intermittently at an early stage of the disease. These manifestations are, principally, simple or paroxysmal tachycardia, auricular fibrillation and flutter, extra-systoles, and delayed conductivity. Many patients with varying degrees of hyperthyroidism complain of purely cardiac symptoms, and if there are few signs of thyroid defect diagnosis may be difficult. The author describes seven such cases to illustrate certain principles in diagnosis and treatment. He finds determination of the basal metabolic rate a useful guide, but believes that this may not be raised during phases of inactivity, or in slight degrees of hyperthyroidism. The administration of iodine is another valuable diagnostic measure: if slowing of the heart, greater regularity, and loss of nervousness and tremor are produced, and if these symptoms return on withdrawal of the drug, the likelihood of thyroid disorder becomes very strong. Where hyperthyroidism is easily diagnosable, iodine should only be given as a pre-operative measure, thyroidectomy being performed before the secondary reaction sets in. From his cases, all of which showed improvement or cure after thyroidectomy, the author deduces that the absence of tremor, glandular enlargement, or eye signs does not necessarily exclude a diagnosis of hyperthyroidism. He also concludes that, in the absence of a definite etiological factor in a case of cardiac disease, no examination is complete that does not thoroughly investigate the activity of the thyroid gland.

548. Spontaneous Recoveries from Diphtheria.

ACCORDING to F. HAMBURGER and J. SIEGL (*Munch. med. Woch.*, September 13th, 1929, p. 1537), during the last five years 20 cases of mild faucial or nasal diphtheria, confirmed by bacteriological examination, have been treated in the Graz University Children's Clinic without antitoxin; all made an uncomplicated recovery, with the exception of one child, in whom the nature of the acute attack had not been recognized, who developed paralysis. Of the 20 cases, 15 were Schick positive shortly after recovery, and in 11 the reaction was examined again from four to twenty-three months later. Among 8 originally Schick-positive, 6 were still positive and 2 had become negative. Of the remaining 3 who were originally negative, 2 were unchanged, but one had become positive. In only one case was an estimate of the amount of antitoxin in the blood made, the amount being less than 0.004 unit per c.cm. The authors conclude that in a large number of cases of spontaneous recovery from diphtheria free antitoxin is not to be found in the blood, and therefore that in addition to antitoxin other antibodies must be responsible for recovery from the disease. Comparatively few persons contract diphtheria; Schick-positive carriers often escape, while Schick-negative individuals, less frequently, may contract the disease or become Schick-positive again. The authors are inclined to regard wholesale immunization against diphtheria as premature, and consider that the question requires further study.

549. Hospital Epidemic of Erythema Infectiosum.

A. SIWE (*Monats. f. Kinderheilk.*, October, 1929, p. 152) records an epidemic of twelve cases of erythema infectiosum which occurred in the University Children's Hospital at Lund. The ages of the patients ranged from 2 to 11 years, and the incubation period ranged from seven to twelve days. In most of the cases the temperature rose to more than 102.2° without any complications being observed. The disease proved contagious in 30 per cent. Prodromes in the form of headache, somnolence, and anorexia were noticed in a few cases. The general condition was good throughout, and the duration of the disease was from six hours to seven days or more. The blood picture showed no pronounced changes. In several patients there was a recurrence of the eruption at irregular intervals, but the recurrences did not necessarily exhibit the same appearance or distribution as the primary eruption. In only two cases did the erythema present the typical circinate appearance; in the others it was more like scarlet fever or measles. One child had extensive oedema, and considerable cutaneous and subcutaneous haemorrhages. Sensitiveness to tuberculin appeared to be distinctly increased in several cases after the disease had terminated.

550. Acute Leukaemia.

S. L. WARREN (*Amer. Journ. Med. Sci.*, October, 1929, p. 490) comes to the following conclusions from a study of 113 cases of acute leukaemia, 85 of which have been reported in the literature since 1917 and 28 have come to necropsy within the last ten years at the allied hospitals of the Harvard Medical School and the Strong Memorial Hospital of Rochester. Acute leukaemia is not a rare disease. The constancy of its history, course, clinical indications, and blood and tissue findings is remarkable both in myelogenous and in lymphatic leukaemia. Acute leukaemia is essentially a disease of infants and young adult males, but in the fourth decade females are more frequently attacked. The duration of the disease is short: 84 of the 113 patients died within two months of the onset. Acute myelogenous leukaemia is frequently incorrectly diagnosed as lymphogenous in type because the primitive bone marrow cells are mistaken for lymphocytes.

551. Prophylaxis by B.C.G. Inoculation.

J. HEIMBECK (*Presse Méd.*, October 26th, 1929, p. 1391) publishes the results of inoculating with B.C.G. vaccine a series of hospital students; the injections were limited to those who gave a negative Pirquet reaction, since it was found that they were more likely to develop tuberculous trouble than those whose reaction was positive. The students were kept under constant observation for over three years. It was found that those who had received the injections showed a decided immunity to tuberculous developments: thus, out of 44 vaccinated in 1927 only one had a slight pleurisy, while 28 out of 100 non-vaccinated students contracted various forms of tuberculosis. Comparing the tuberculous morbidity between the vaccinated and non-vaccinated, it was found that 41 per cent. of the non-vaccinated developed tuberculous troubles (erythema nodosum, pulmonary infiltration, and pleurisy), while of 136 vaccinated only 3 developed slight pleurisy.

552. Gastric Response to Tobacco Smoking.

I. GRAY (*Amer. Journ. of Surg.*, October, 1929, p. 489) records the results of an investigation made in 100 cases of male adults between the ages of 20 and 40 who had gastric complaints with an associated history of smoking for at least five years. It was found that 50 patients with functional gastric symptoms showed variations in secretory and motor findings. Those who had heartburn, duodenal ulcer symptom-complex, or pylorospasm showed a hypersecretion and a distinct hyperacidity when smoking was allowed on a fasting stomach or two hours after a test meal; gastric secretion was also increased, with hypoacidity, in gastritis patients who smoked either before or after a test meal. In these patients peristaltic activity was decreased and the emptying time increased, while in the remainder peristalsis was increased and the evacuation slightly delayed. In cases of hyperacidity peristalsis was either normal or increased, with normal emptying time; in those who had hypoacidity or anacidity peristalsis was decreased and emptying time increased. The remaining 50 patients were those in whom a positive diagnosis of duodenal ulcer had been made with a history of periodicity and chronicity of ulcer symptoms for several years. These showed an increase in acidity and gastric secretion with smoking on a fasting stomach or two hours after a test meal; a few, however, showed a decrease in acidity after smoking. Smoking before the barium meal produced marked hyperperistalsis, whereas smoking fifteen minutes after showed a slight increase in peristalsis. The emptying time in these cases was practically normal. Five patients who were excessive smokers and showed no improvement of clinical symptoms were tested with the denicotinized products, and it was found that there was little change in the secretory or motor response as compared with the test when the usual nicotine product was used. There was no allergic reaction to tobacco extract in any of these patients upon skin tests, and it was found that the proteolytic action of pepsin was uniformly the same in all except four patients who showed a subacidity.

Surgery.

553. Spina Bifida Cystica.

J. LEVEUF (*Bull. et Mém. Soc. Nat. de Chir.*, October 26th, 1929, p. 1080) reports fourteen cases of *spina bifida cystica* recorded by Yovichitch of Belgrade, and describes the technique employed by the latter in the operative treatment of these cases. In each case the method of treatment was as follows: careful dissection of the sac; ligature and division of the pedicle; closing of the aperture by drawing together the neighbouring muscles; and suture of the skin. Of the fourteen cases operated on four patients died; in three cases the result was excellent, with uninterrupted convalescence, and the patients were found to be in good health three and a half years, two years, and eight months after operation. In three other cases incontinence of urine and faeces persists owing to weakness of the sphincter muscles; in one other case a slight hydrocephalus developed at the end of a year. Leveuf divides spina bifida into the variety which is not closed, and that which is covered with epidermis or skin. Out of fourteen cases of the first form, only one patient, who was operated on when only three hours old, was known to be alive and well eight months later, although suffering from muscular weakness of the lower limbs. Out of sixteen cases of spina bifida which were covered with skin, thirteen were operated on, and, of these, six recovered completely without any resultant disability; four recovered, but were left with incontinence or weakness of the leg muscles; two died from hydrocephalus, and one at the time of operation.

554. Rupture of the Bladder.

M. F. CAMPBELL (*Surg., Gynecol. and Obstet.*, October, 1929, p. 540) records his observations on 55 cases of ruptured bladder, with 35 deaths, which occurred at the Bellevue Hospital, New York, between January 1st, 1914, and July 1st, 1928, among slightly over 300,000 surgical cases. The majority of the patients were adult males, although the youngest was a girl aged 3 years. He remarks that the condition is due to trauma, and is favoured by vesical distension, alcoholism, which was present in 19 cases, and pre-existing disease of the vesical walls, such as tuberculosis. One-third of the cases were injured in or by a motor car, 23 were assignable to industrial accidents, and in 11 instances rupture followed a fall. In most cases shock follows the injury. Involvement of the urinary tract is suggested by intense bladder tenderness, dysuria, haematuria, or absolute inability to pass urine. If an intraperitoneal rupture has occurred the early symptoms of peritonitis may be present. In most cases the diagnosis is not easy, and an early and speedy operation is imperative. Free suprapubic bladder drainage is of the utmost importance. If intraperitoneal rupture has not occurred the prognosis is twice as good as when such a rupture is present. The chances of recovery are greatly increased when the patient has survived the first week.

555. Treatment of Acute Gastric Haemorrhage.

H. BOCK (*Zentralbl. f. Chir.*, October 12th, 1929, p. 2575) suggests that the mortality following haemorrhage from gastric or duodenal ulcer would be considerably reduced if patients were treated surgically at an earlier stage—that is, as soon as possible after a severe haemorrhage, without awaiting under medical treatment a recurrence of the bleeding and the consequent deterioration in the patient's condition. He advocates operation immediately after a large transfusion has been given. He considers that the patient's recovery from the loss of blood is thus accelerated; moreover, there is less risk of secondary septic infection, consequent on the prolonged restricted diet necessitated by medical treatment and the lowered general resistance. In illustration of this point he records two cases in which transfusion alone was performed; the patients succumbed to suppurating parotitis and multiple pulmonary abscesses respectively. In addition to transfusion, the operative technique advocated is resection, if practicable under local anaesthesia of the abdominal wall combined with splanchnic anaesthesia; where this is impossible Bock recommends posterior retrocolic gastro-enterostomy.

556. Movable Bodies in the Hip-Joint.

E. POLACCO (*Arch. Ital. di Chir.*, October, 1929, p. 671) records three illustrative cases in women, aged 35, 42, and 23 respectively, of movable bodies in the hip-joint secondary to osteo-arthritis deformans. In only one of the three cases was the etiology of the arthritis known—namely, gonococcal infection. Although Polacco's cases occurred exclusively in women, the male sex is usually more affected than the female by movable bodies in the joints. Age has no special influence on their occurrence. The larger joints are most frequently involved—namely, the knee, elbow, shoulder, in order of frequency—affection of the hip-joint being relatively rare. The number, weight, and consistency of these bodies vary considerably. They may occur singly or in very large numbers, range in weight from a few centigrams to 15 to 20 grams or more, while their consistency may be soft, fibrous, or bony. The predominating symptoms in Polacco's cases were those of arthritis deformans. An excellent result was obtained by operation in each case.

Therapeutics.

557. Desiccated Stomach in the Treatment of Pernicious Anaemia.

FOLLOWING the demonstration by Castle that the stomach of normal persons secreted a substance which could extract a blood-maturing principle from meat, Sharp concluded that the feeding of stomach should have the same effect in pernicious anaemia as liver. A preparation was accordingly made by desiccating whole hog stomach so that 30 grams of the dried substance represented 190 grams of the fresh tissue. In later experiments the fat was removed by petroleum benzine, so that 30 grams of the final material represented 218 grams of fresh tissue. The latter was found to be a great improvement, since it had very little odour and practically no taste. C. C. STURGIS and H. ISAACS (*Journ. Amer. Med. Assoc.*, September 7th, 1929, p. 747) report the effect of the administration of this residue in three cases of pernicious anaemia. Daily feedings of from 15 to 30 grams in suspension in water were given. In all the cases there was a prompt and very active response, characterized by an increase in the percentage of reticulated red blood cells, which was comparable with, if not greater than, the increase in the reticulocytic percentage induced by liver extract. One suggestion as to the origin of the active principle in desiccated stomach is that an enzyme or similar substance is present which may act on the protein in the stomach tissue. Another is that there may be a supply of the active hematopoietic principle itself present in the stomach wall, as it apparently is in kidney and liver.

558. E. A. SHARP (ibid., p. 749) agrees that desiccated whole hog stomach contains an anti-anaemic factor, and that it produces a symptomatic response as vigorous and effective as that obtained from liver or liver extract. The deficient element in pernicious anaemia is apparently unrelated to fat digestion and assimilation, as is evidenced by the maintenance of weight and good assimilative ability of the organism during severe crises. Achlorhydria, persistent in the disease, is probably existent in the predisposed person for several years before full development of the hematopoietic syndrome. Persistent achlorhydria, anaemia, and liver treatment are possibly correlated, and it appears rational to assume that liver or liver extracts supply an essential substance, readily synthesized from ordinary food in normal gastric conditions, but imperfectly or scantily converted in achylous digestion. If the achlorhydria is caused by an acquired or congenital defect of the glandular portion of the gastric mucosa, it seems reasonable to believe that tissues of the stomach might be therapeutically applicable from the standpoint of organ specificity.

559. Ovarian Hormone Therapy.

IN the opinion of E. L. SEVRINGHAUS and J. S. EVANS (*Amer. Journ. Med. Sci.*, November, 1929, p. 658) the belief that the ovary produces a hormone has become a certainty with the demonstration by Allen and Doisy of the active preparations from the Graafian follicle. The therapeutic effect of amniotin, an ovarian hormone, has been studied in a series of 25 women who were suffering from menopausal and menstrual disturbances. The cases were arranged in five groups. Group 1 included those who had ceased to menstruate, or were doing so irregularly; Group 2 those in which a menopause was suspected because of menstrual changes; Group 3 those showing an association of a known menopause with a psychosis; Group 4 those presenting an association of angio-neurotic oedema with ovarian disturbance; and Group 5 included only those infantile cases with no apparent involvement of the thyroid or pituitary glands. Amniotin, a preparation of the Allen and Doisy hormone obtained from the amniotic liquor of cattle, is an aqueous solution, prepared for subcutaneous injection in a concentration of 10 rat units per c.cm. Though much larger doses are recommended by the manufacturers, the authors consider that doses of about 10 units daily are adequate, and may occasionally be excessive; 50 units is said definitely to be too large. Pessaries containing 10 units per gram were successfully used in seven

cases. This series of patients indicated that amniotin produces an active therapeutic effect on women. It gave very satisfactory relief in the hot flashes, insomnia, nervous instability, and headaches attributable to the menopause, artificial or spontaneous; moreover, the improvement noted in angioneurotic oedema associated with a partial menopause confirmed this view. Most convincing of all is said to be the development promoted in the "infantile type" as the result of its administration. The authors believe that the relief experienced by some of the patients from the use of lutein was largely due to its follicular content.

560. L. G. DITTEL and F. RAAB (*Wien. klin. Woch.*, October 24th, 1929, p. 1374) remark that, despite Allen and Doisy's attempt to standardize ovarian extract by the injection of castrated mice, the conclusions as to its value are still contradictory. Clinical benefit does not follow *per passu* with number of "mouse units" injected; this may be due to the prompt excretion of the greater part of a large dose. Many cases of amenorrhoea have, however, been benefited; two cases are cited of young women who had not menstruated for a year, after which the injection of 300 mouse units twice weekly gave them a normal period after courses lasting three and five weeks respectively. A young nervous woman was treated unsuccessfully on psychotherapeutic lines for delayed and weak menstruation; after about ten daily injections, each of 100 units, menstruation appeared, but eight days prematurely. Menorrhagia and metrorrhagia were often benefited, according to the authors. A girl suffering from menstrual haemorrhage lasting three weeks had been treated unsuccessfully with many remedies; intravenous injections of ovarian extract were started and proved to be successful for the time being. The authors report that many cases of dysmenorrhoea were improved, and a woman medical practitioner was cured after a few injections of 100 units; this case is considered important as it presumably eliminates the factor of suggestion. Menopausal malaise was sometimes cured by injections of only 24 units twice weekly. An artificial menopause often proved amenable to this treatment, but the authors admit that in this condition and in the menopause occurring naturally it sometimes fails completely, or needs as adjuvants drugs and psychotherapy. To demonstrate the wide possibilities of the application of ovarian extract therapy three cases are cited respectively of universal pruritus, Quincke's oedema, and repeated abortion. The first case was complicated by dysmenorrhoea; in the second patient the oedema developed only at menstruation. Each of the three patients was cured by ovarian injections. The authors give the warning that since the causes of disturbed ovarian function are not always known it cannot be expected that every case will respond to ovarian extract; the cause is often extra-ovarian, as, for instance, a pituitary lesion.

Neurology and Psychology.

551. A Pelvic Crossed Reflex.

Two reflexes which may be of use in diagnosing medullary lesions of the upper part of the dorsal segment of the cord are discussed by A. BROCKAERT (*Presse Méd.*, November 6th, 1929, p. 1440), of which one, the periosteal or medio-pubic reflex, was previously described by Guillain and Alajouanine. The other reflex has been named by Brockaert "the crossed reflex of the pelvis." The medio-pubic reflex is obtained by placing the subject extended on the back with the legs raised and bent and the knees somewhat apart, as in the gynaecological position. Percussion over the symphysis pubis then elicits a double response: a contraction of both the left and right adductors, while the thighs are adducted and exceptionally drawn towards the pelvis by contraction of the flexors; and a contraction of the abdominal muscles. The reflex depends, however, on the adipose tissue not being too great, and the abdominal wall possessing normal tone. It may be exaggerated in various bilateral pyramidal affections (scleroses and medullary compressions), when contractions of the pectoralis major, platysma, and small facial muscles can also be noted. It may also be exaggerated on one side only in certain paraplegias, and especially in unilateral pyramidal changes with hemiplegia. It is absent in chronic polyneuritis, acute anterior poliomyelitis, and in medullary compressions of the dorsal segment of the cord. The crossed reflex, which occurs in the same diseases as the medio-pubic, is obtained by percussing over the anterior superior iliac spine with the patient in the position previously described. The response consists in a contraction of the adductors of the opposite limb, while the knee of this side is drawn inwards. Discussing its evolution, Brockaert enumerates the ventral muscles of the thigh, and states that the afferent passage of the reflex comprises a "receptor" (the ilium), an intermediate mass consisting of the lower lumbar vertebrae and sacrum, and the sensory neuron of the posterior horns of the cord from the second lumbar to the second sacral. The efferent path commences in the neuron of the anterior horns of the opposite side, follows the lumbar plexus (more especially the obturator nerve), and terminates in the energized group of the thigh muscles, which is, phylogenetically, of ventral origin. This, however, Brockaert admits, does not explain the selection of intermediary neurons in the conduction of the impulse to the opposite (contralateral) side.

562. Epidemic Encephalitis with Cerebellar Symptoms.

A. JENKINS (*Arch. Neurol. and Psychiat.*, September, 1929, p. 469), who records two illustrative cases in men aged 18 and 56, states that though numerous cases of epidemic encephalitis with involvement of the vestibular connexions have been reported, a predominance of cerebellar symptoms is less frequent. In most cases the cerebellar symptoms, when present, are overshadowed by the Parkinsonian syndrome. In Jenkins's first case the typical symptoms of epidemic encephalitis—namely, drowsiness, headache, diplopia, and impaired convergence—were associated with a cerebellar gait, staggering, hypotonia, and dysmetria in the extremities of the left side. In the second case the cerebellar symptoms were still more pronounced. Jenkins has collected five other cases from the literature in which the cerebellar syndrome was present in encephalitis, as well as another seven with merely isolated cerebellar signs. Cell changes in all parts of the cerebellum have been found after death in cases of encephalitis in which cerebellar symptoms did not occur or were not prominent.

563. Unusual Symptoms of Intracranial Tumours.

C. O. HAWTHORNE (*Clin. Journ.*, October 30th, 1929, p. 517) points out that one or all of the cardinal symptoms of intracranial tumours—namely, headache, vomiting, and optic neuritis—may be absent, and that their manifestation, even when present, is not necessarily continuous. There may be periods of complete freedom from headache; vomiting may yield to rest and lead to an erroneous diagnosis of gastric catarrh, etc.; while optic neuritis often fails to be observed owing to lack of use of the ophthalmoscope. Doubtless the cause of the variation in the symptoms is alteration in the intracranial conditions, the symptoms being due to secondary consequences such as congestion, oedema, inflammation, and haemorrhage, rather than directly to the tumour. Certain symptoms which do not suggest the existence of a growth may be present; among these are abnormal sleepiness and neuralgia. Two series of cases, in which no distinctive evidence of tumour was noted, are reported to illustrate this statement. In the first series of three cases the predominant symptom was an abnormal sleepiness; necropsies revealed tumours in the right optic thalamus in one case, and in the right temporo-sphenoidal lobe in another, while, in the third, all the symptoms disappeared under tonic and rest treatment, indicating that occasionally morbid sleepiness may occur apart from intracranial tumour. In the second group, also of three cases, pain was the conspicuous symptom; this was not described as headache or pain in the head, but as neuralgia. A necropsy was not allowed in one case, but in the other two this procedure revealed tumours on or related to the deep surface of the great wing of the sphenoid with thickening of the neighbouring membranes. In this way a complete explanation was obtained of the neuralgic pain in the peripheral distribution of the fifth cranial nerve in one case, and in the other of neuralgia which had previously been attributed to carious teeth. Hawthorne emphasizes the importance in such cases of careful and repeated ophthalmoscopic examinations, the performance of tests for syphilis, and the preparation of special skiagrams.

Obstetrics and Gynaecology.

564. Treatment of Salpingitis.

C. E. FARR and R. T. FINDLAY (*Surg., Gynecol. and Obstet.*, November, 1929, p. 647) state that salpingitis is a definite clinical entity; although it simulates and is simulated by other conditions, it possesses many characteristic features. A detailed study of 541 cases treated in the New York Hospital is given, and the importance of diagnosis, differential diagnosis, and proper treatment is emphasized. It is important that care should be taken to obtain a very accurate and complete history, and to make a thorough physical examination in salpingitis in order to avoid diagnostic errors; moreover, thoroughness and accuracy are essential, as the disease must not be treated by routine or without deliberation. In this series of cases the following, in the order of their incidence, were the most frequent and most important conditions to require differentiation: appendicitis, ectopic gestation,

cystoma of the ovary, uterine fibromyoma, retroversion of the uterus, endometritis, and ureteral colic. Various other conditions encountered are enumerated. In discussing complications the authors state that, although diseases of the appendix, uterus, and ovaries are most often associated with salpingitis, there are many other conditions which complicate it. While each case must be treated individually, the following general rules as to operation are advanced. Acute cases should never be operated upon; even an acute fulminating salpingitis with general peritonitis should not receive surgical treatment if the diagnosis is reasonably certain, since the operation frequently causes spread of the peritonitis with resulting death. When there is a reasonable doubt whether salpingitis or acute appendicitis is present, an operation should be advised. When the abdomen is opened on another diagnosis and acute salpingitis is found, removal of the tubes, except in young girls, is usually advisable. No operation should be performed during an acute exacerbation, since it would probably result in spreading of the infection to the peritoneum and surrounding tissues. In chronic salpingitis the tubes should be removed if they are not patent; if they are, removal is not advisable. Tubes in acute salpingitis and in exacerbations of a chronic tuberculous salpingitis should be allowed to subside. All ovarian tissue not definitely grossly diseased should be left in the body.

565. Pregnancy after Tubal Insufflation.

O. DAUWE (*Le Scalpel*, November 9th, 1929, p. 1221) reports a series of 150 consecutive cases of sterility on which he performed insufflation. In most instances the presence of imperforate tubes was the principal cause of the sterility, although stenosis of the cervix and uterine deviation or displacement were sometimes associated. The duration of the sterility was from three to seven years. Of the 150 cases only 40 had been definitely followed up at the time of the report. Of these, 17 patients had been definitely benefited, 3 having given birth to two children, 8 to one child, while 3 were then pregnant and 3 had aborted; 23 remained sterile up to the time of reporting. The author first examines the vaginal secretions bacteriologically because, even with antiseptic precautions during the operation, a case had occurred in which a small collection of pus appeared in the pouch of Douglas after insufflation. After freeing the vagina from infective organisms, insufflation is performed about eight days after the menses, oxygen purified by passage through a Woulfe bottle containing ether being employed, and a Bouffite manometer being connected with the rubber tube leading from the Woulfe bottle to the uterus. After disinfecting the vagina with iodized ether a blunt metal cannula attached to the tubing is passed into the uterus; in cases of impermeability the needle of the manometer remains at a pressure of 22-23 cm. of mercury, but this diminishes rapidly if the tubes are free. Simultaneous suprapubic auscultation alters the special souffle caused by the passage of the oxygen into the abdomen to be heard, and insufflation is then stopped, 10 to 12 c.mm. of lipiodol being then injected through the same cannula. After several seconds a radiographic plate is taken; if no lipiodol is seen in the peritoneal cavity another plate is taken after six to twelve hours. If the tubes are patent free lipiodol becomes visible in the peritoneal cavity.

566. Sympathectomy of the Hypogastric Artery.

C. CHIANELLO (*Arch. Ital. di Chir.*, August, 1929, p. 365) records the effect of sympathectomy of the hypogastric artery on the ovaries and uterus of dogs. He found that the ovary on the operated side was more developed, contained more follicles, and matured earlier; the muscular part of the uterine horns was not much affected, but the mucosa was definitely thickened and the glandular tubules were fuller. The blood vessels showed no appreciable alteration in calibre. The therapeutic bearing of these experiments is the remedying of certain uterine maldevelopments, and the correlated pelvic pain. The author suggests that the beneficial effect sometimes observed after dilatation of the cervix may perhaps be partly due to disturbance of the sympathetic nerves round the cervix. Drawings of the histological appearance of the ovary after operation and a bibliography of recent literature are supplied.

567. Diagnosis of Tuberculosis of the Uterine Appendages.

J. WITLOCH (*Zentralbl. f. Gynak.*, October 26th, 1929, p. 2737) points out that although it has been shown that in 50 per cent. of cases of tuberculous disease of the adnexa the endometrium is also involved, diagnostic curettage is undesirable because it carries with it the risk of miliary spread of the disease; moreover, it is unsatisfactory, since tubercles may not be visible in the scrapings on account of their sparse and patchy distribution. If small nodules are palpable in the pouch of Douglas the author prefers to excise one of these for diagnosis. Exploratory laparotomy he considers unjustifiable in this condition; he advocates, however, exploratory puncture as the most satisfactory method of differentiating tumours of the appendages preliminary to the conservative treatment of subacute and chronic swellings, and particularly of tuberculosis in this region. For cystic swellings a long hollow needle is used; for solid tumours a modification has been constructed. Microscopic examination of the fluid is generally sufficient, but, for the diagnosis of tuberculosis, injection of the aspirated matter into a guinea-pig is frequently necessary. The danger of the puncture method of diagnosis is no greater than that of examination under anaesthesia, and the risk of injury to the bladder or intestine is considered to be negligible with careful technique, since in a long series of diagnostic punctures he has had no case of injury or infection.

Pathology.

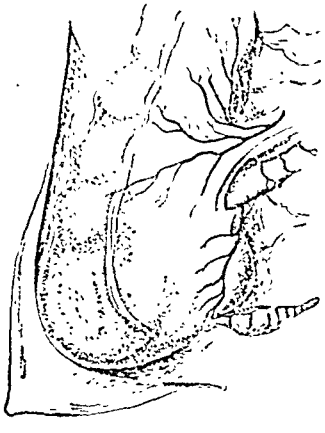
568. The Skin as a Portal of Entry in Br. abortus Infections.

A. V. HARDY, MARGARET G. HUDSON, and C. F. JORDAN (*Journ. Infect. Dis.*, October, 1929, p. 271) adduce evidence that *Br. abortus* frequently gains access to the body through the skin. In their experiments two strains of this organism were used; both were isolated from human cases of undulant fever, but one was typed as a bovine, the other as a porcine strain. The growth from a forty-eight-hour agar slope was washed off with saline solution, and standardized by opacity to a strength of about 2,000 million organisms per c.cm.; 0.1 c.cm. of this suspension was then rubbed gently on to the abdominal skin of different series of guinea-pigs, and to another series the same dose was given by the mouth. Agglutination tests were made at intervals up to eight weeks; positive reactions were regarded as indicating that infection had occurred. The results were as follows. Of 21 guinea-pigs inoculated on the shaved and superficially abraded skin, all developed infection; of 31 inoculated on the shaved but not abraded skin, 28 developed infection; of 32 inoculated on the unshaven, unabraded skin (the hair had merely been clipped), 25 developed infection; and of 18 fed by the mouth, 4 developed infection. It would appear, therefore, that in the dosage used the organisms gain access to the body more readily by the skin than by the mouth. In another series of experiments it was found that if massive doses—ranging from 1,000 million organisms to half of a forty-eight-hour agar slope—were given by the mouth, 17 out of 19 animals became infected. An epidemiological survey was then made of the employees in a packing-house plant dealing with the fresh tissues of hogs. Of 118 employees engaged in killing the animals and cutting up the carcasses, 21 per cent. agglutinated *Br. abortus* to 1 in 80 or higher; of 49 engaged in trimming the edible portions, 8 per cent. showed agglutinins; while of 50 having little or no direct contact with the carcasses, only 2 per cent. contained agglutinins. Of 25 employees with a titre of 1 in 80 or higher whose histories were investigated 14 gave a definite history of undulant fever or a history suggestive of this condition. The authors conclude that both in experimental animals and in man *Br. abortus* frequently gains access to the tissues through the skin.

569. The Nature of Alastrim.

H. ALDERSHOFF and A. W. POT (*Nederl. Tijdschr. v. Geneesk.*, September 14th, 1929, p. 4232), like Leake and Force, Blaxall, and Green, and unlike Baujean, succeeded after direct cutaneous inoculation of apes with alastrim in obtaining a vesicular eruption which lasted for weeks. In subsequent passages through apes the eruption was not confined to the site of inoculation, but became generalized, the rash not appearing all at once. In this last respect the alastrim shows a point of resemblance to chicken-pox and differs from variola. The present authors agree with other investigators that the virus of alastrim resembles that of variola, and that the relation is closer than with the vaccine virus. Whether this resemblance is due to a close relationship and nothing more, or whether the alastrim virus is derived from the variola virus, is not yet known. Gins's view that the alastrim virus is a form of variola virus which has undergone passage several times through immune persons is improbable, since alastrim did not first develop in countries with a well-vaccinated population, but in such countries as the Cameroons or Samoa, where well-vaccinated persons are scarce. It seems more probable that the animal and not the human being is responsible. Since variola virus may be converted into vaccine virus by passage through a cow, it is not surprising that by passage through another, and so far unknown, animal an alastrim virus may arise which differs less from the virus of variola than from that of vaccine virus.

Among the Results of Constipation



Distended and sagging cæcum compressing and obstructing blood supply of vermiform appendix.

are not only the grave toxæmias of which much has been learned in recent years, but also conditions arising from mechanical factors, due to displacement of the viscera or pressure exerted by the distended bowel.

AGAROL Brand Compound, combining three essential actions: lubrication of the intestinal tract, restoration of the peristaltic force, and softening of the impacted fæces, generally aids in overcoming the effects of constipation. Gentle but forceful in action, Agarol Brand Compound assists the organism back to regular normal evacuation by restoring *peristaltic function*.

The dependability of Agarol Brand Compound has definitely enlisted the interest of the medical profession, who in most cases of acute or chronic constipation, successfully prescribe Agarol Brand Compound — one tablespoonful on retiring.

A Liberal Quantity For Trial To Physicians

FRANCIS NEWBERY & SONS, LTD.
31-33 BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion with Phenolphthalein and has these advantages: Perfect emulsification; stability; pleasant taste without artificial flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

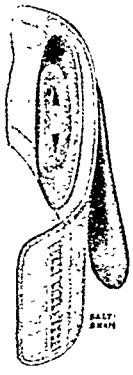
SALIENT POINTS

of

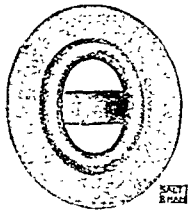
SALT'S (Patent) COLOSTOMY BELT

1. Detachable receiver sterilizable by boiling.
2. Mouth of bag kept open for free entry of fæces.
3. Easy removal and cleaning of Bag, without removal of Belt.
4. No crevices to hold fæces, and therefore little odour.
5. Less bulk, greater comfort, and more sanitary than any other.
6. Rubber portions far more durable than in the old style belt.

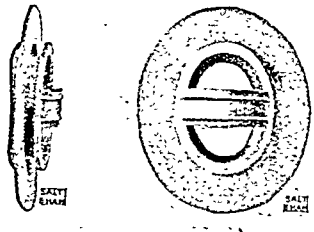


Showing attachment of receiver and bag to belt.

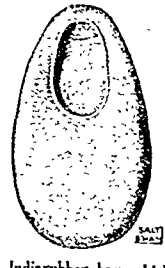
Details of Receiver and Bag
STERILIZABLE BY BOILING



Showing rubber receiver with pad fitting next to body and rubber flange to prevent belt becoming soiled.



Showing other views of receiver. See groove over which aperture in bag is stretched and curved bridge to hold open mouth of bag.



Indiarubber bag which can be detached at will for cleaning.

Showing bag attached to receiver.

Full Particulars on Request.

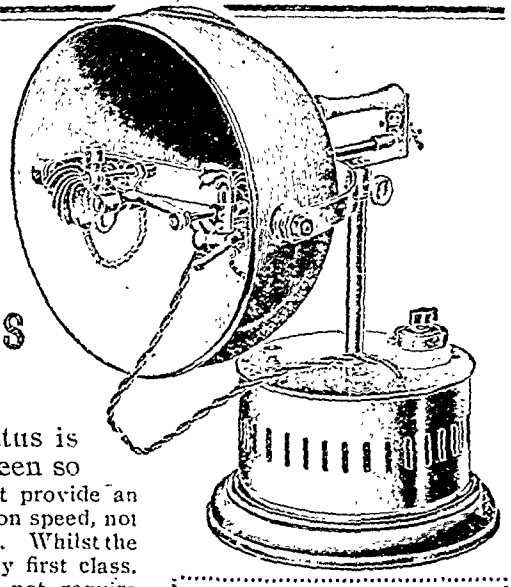
HAVE YOU fully realized the therapeutic value of Actino-Therapy and its wide range of application in YOUR PRACTICE?

THOUSANDS OF TREATMENTS ARE ADMINISTERED DAILY



"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.

Specification :

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: 30 TREATMENTS 3d.

Price:

For use on Direct Current ... £12
For use on Alternating Current £18

THIRTY OTHER TYPES.

Ask for Catalogue No. 142.

HIRE.—Where required Ultra-Violet Light Apparatus may be hired for individual cases.

NORVIC Reg'd

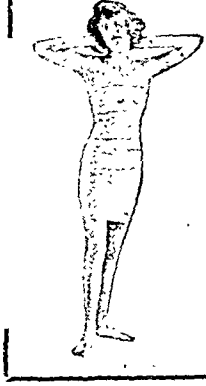
Abdominal Crêpe Binders

Their flexible yet firm support is essential in surgical cases and invaluable in maternity. Elasticity easily restored by washing. Fully guaranteed.

As used by leading Hospitals

PRICES:—6 in. width, 4/6: 8 in. width, 6/-; 11 in. width, 8/3.

Stocked by all the leading Chemists and Druggists, BOOTS 800 branches; TIMOTHY WHITE Ltd.; TAYLORS DRUG STORES; and PARKES CHEMISTS Ltd.



FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Recommended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reports on request.

An ACHIEVEMENT

IN SCIENTIFIC CONSTRUCTION

"EMESAY POPULAR" MODEL OPERATING TABLE

£45

100% BRITISH.

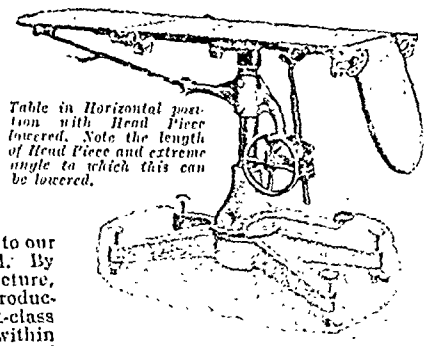

Table in Horizontal position with Head Piece lowered. Note the length of Head Piece and extreme angle to which this can be lowered.

ESSENTIALLY similar in design to our well-known "Universal" Model. By the experience gained in its manufacture, and the use of modern methods of production, we are able to offer a first-class heavy and stable Table at a price within the reach of the smaller Hospitals and Nursing Homes.

Its range of movements makes it suitable for any operation required by Modern Surgery.

The perfection of its design has been proved by the unqualified commendation expressed by users of the original model of which the Popular Model is an offspring.

SEND FOR DESCRIPTIVE BOOKLET (B) or call at any of our Showrooms for demonstration.

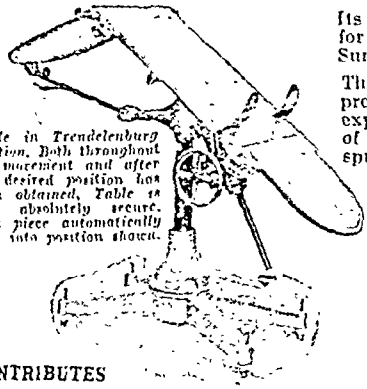

Table in Trendelenburg Position. Both throughout the movement and after the desired position has been obtained, Table is held absolutely secure. Foot piece automatically falls into position shown.

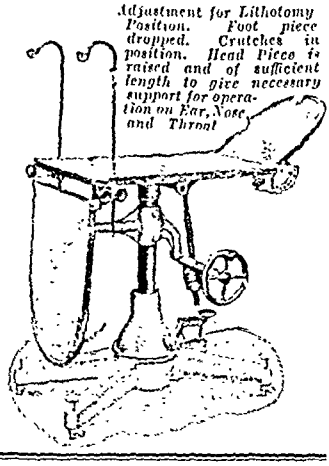

Adjustment for Lithotomy Position. Foot piece dropped. Crutches in position. Head Piece is raised and of sufficient length to give necessary support for operation on Ear, Nose and Throat

ASTHMA

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 39B.

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given *hypodermically*, and its action is short lived. Vapo Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 10 8 bottles.

FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel.: Langham 1166.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) CH.M.EDINBURGH. M.C.GA.&TAB.
F.R.C.S.EDINBURGH. M.S.LONDON.
And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.
¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.
¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.
¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

Applications, stating age, nationality, qualifications, and experience, accompanied by copies of not more than three recent testimonials, to be sent to the Secretary as soon as possible.

December 11th, 1929.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes, to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank	Service in Rank	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
Lieut		500	150	1st
			150	2nd
Capt			150	3rd
	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years service as Major	1250		
Lieut Col	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1750		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum £
After 17 years' service for pension ...	... 400
,, 18 ,, ,, ,, ...	... 430
,, 19 ,, ,, ,, ...	... 460
,, 20 ,, ,, ,, ...	... 500
,, 21 ,, ,, ,, ...	... 540
,, 22 ,, ,, ,, ...	... 580
,, 23 ,, ,, ,, ...	... 620
,, 24 ,, ,, ,, ...	... 660
,, 25 ,, ,, ,, ...	... 700
,, 26 ,, ,, ,, ...	... 750
,, 27 ,, ,, ,, ...	... 800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in January to make nominations, and the selected candidates will be required to attend a course of instruction commencing on or about the 1st February, 1930.

APPOINTMENTS.—Contd.

City and County of Bristol.

ASSISTANT RESIDENT MEDICAL OFFICER.

The Bristol Health Committee invite applications for the post of Assistant Resident Medical Officer, HAM GREEN FEVER HOSPITAL AND SANATORIUM. Salary £300 per annum, with board, residence, and attendance. Candidates should have held a resident appointment.

The salary will be subject to a percentage deduction in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the selected candidate must undergo medical examination.

The appointment is for one year and the selected candidate will be required to remain for that period.

Canvassing members of the Council will disqualify.

Applications to be made not later than December 30th, on special form to be obtained from the Medical Officer of Health, 40, Prince Street, Bristol.

The Royal Infirmary, Bradford.

RESIDENT SURGICAL OFFICER (male) required to supervise the work of four House Surgeons and be generally responsible for the surgical work of the Hospital.

Candidates must be single and legally qualified, have had previous Hospital experience, and be prepared to enter on duty at the beginning of February, 1930. Salary £250 per annum, with board, residence, and washing. There are 215 beds and six resident officers. Applications, stating age, qualifications, and previous experience, with copies of not more than three recent testimonials, to be received by the undersigned not later than Tuesday, December 31st.

J. J. BARRON, Secretar. Supt.

The London Female Lock HOSPITAL,
283, Harrow Road, W.9. (Founded 1746.)

HON. OBSTETRIC SURGEON.

The Board of Management invite applications for the above appointment. Copies of the laws relating to this appointment can be obtained from the Secretary. Applications, enclosing copies of not more than three testimonials, should be lodged with the undersigned on or before January 6th, 1930.

The appointment will be made at a special Court of Governors on January 9th, 1930.

By Order of the Board,
H. J. EASON, Secretary.

Rochdale Infirmary and DISPENSARY. (110 Beds.)

Wanted, JUNIOR HOUSE SURGEON (male). Salary £175 p.a., including board, residence, and laundry. Applications, stating age, nationality, etc., together with copies of three recent testimonials, to be sent to the Secretary, endorsed "House Surgeon." Conditions of appointment may be had on application to the Secretary.

Infirmary Office, Rochdale. W. WYNNE, Secretary.

Westminster Hospital,
Broad Sanctuary, S.W.1.

There is a vacancy for a HOUSE ANÆSTHETIST. The appointment is a whole-time one, and is of three or six months' duration. Salary £100 per annum (non resident).

Applications should be submitted to the undersigned not later than Saturday, January 4th, 1930.

CHARLES M. POWER, Secretary.

Birmingham Union.
SELLY OAK HOSPITAL.

TWO CASUALTY OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for the appointments of Casualty Officers (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 540 beds divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children, and Infectious Sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-therapeutic, Massage, and Sunlight Departments. Over 2,200 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time.

The officers appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to them by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointments is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointments may be obtained from the Medical Superintendent, Mr. R. P. STANLEY KELMAN, M.B., F.R.C.S. (Eng. & Edin.) at the Selly Oak Hospital.

Applications, *stating age, experience, and qualifications*, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Wednesday, January 8th, 1930.

Union Offices, Birmingham. December 12th, 1929. C. P. BEECH, Clerk to the Guardians.

City of Manchester.
PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM (333 Beds).

ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Preference will be given to applicants with previous Hospital experience; some experience of bacteriology or radiology is desirable.

Salary £300 per annum, with board, residence, and laundry in addition.

The appointment is made in the first instance for a period of twelve months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope, "Medical Officer, Baguley Sanatorium," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must reach him not later than Monday, January 6th, 1930.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of the office, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service. Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
F. E. WARBRECK HOWELL,
Town Clerk.
Town Hall, Manchester. December 6th, 1929.

Tunbridge Wells and Counties
GENERAL HOSPITAL.

Applications are invited for the post of SECRETARY of the above Hospital. Salary £350, rising by yearly increments of £10 to £400. Hospital or institutional experience a recommendation. For forms of application and terms and conditions of appointment, apply to the Secretary (pro. tem.), General Hospital, Tunbridge Wells, enclosing stamped addressed envelope for reply.

The Kidderminster and District
GENERAL HOSPITAL. (120 Beds.)

HOUSE SURGEON required.

Salary £150 per annum, with residence, board and laundry. Applications, with not more than three testimonials, to be sent to the Assistant Secretary, Miss SUSAN SMITH, South Cliff, Kidderminster, on or before Wednesday, January 1st, 1930.

Hartlepool Union.
ASSISTANT RESIDENT MEDICAL OFFICER.

The Guardians invite applications from fully qualified ladies for the appointment of Assistant Medical Officer at HOWBECK INFIRMARY, containing 300 patients, including 90 imbeciles. Salary £500 per annum inclusive, with furnished rooms, washing, and rations.

The appointment is subject to the approval of the Minister of Health and to the provisions of the Poor Law Officers Superannuation Act, 1896, and the lady appointed will be required to devote her whole time to the service of the Guardians, undertake to give Lectures in Surgical and Medical Nursing to Probationer Nurses, and carry out the instructions of the Superintendent Medical Officer.

Applications, stating qualifications, age, and previous experience, should be accompanied by copies of three testimonials, and delivered to the undersigned on or before noon on Friday, December 27th.

By Order,
Union Offices, Hart Road, West Hartlepool. N. JEFFRIES, Clerk to the Guardians.

Durham County Mental Hospital

wanted, a JUNIOR MALE ASSISTANT MEDICAL OFFICER, with a sound knowledge of *Bacteriology and Pathology*, competent to take charge of Laboratory. Age not over 30 years, unmarried. Must be fully qualified and duly registered.

Commencing salary £350 per annum, rising by annual increments of £25 to £450 (if in possession of D.P.M. an additional £50), with board, lodging, washing, and attendance.

The appointment will be made under the provisions of the Asylum Officers Superannuation Act, 1909, and for this purpose the emoluments are valued at £135 per annum.

Applications, stating age, qualifications, etc., with copies of three recent testimonials, will be received up to the 31st instant, and should be addressed to the MEDICAL SUPERINTENDENT, Winterton, Stockton-on-Tees, Co. Durham.

December 14th, 1929.

Manchester Royal Infirmary.
CENTRAL BRANCH, ROBY STREET, MANCHESTER.

JUNIOR HOUSE SURGEON AND CASUALTY OFFICER (LADY).

The Board of Management of the Manchester Royal Infirmary invite applications for the above appointment.

Applicants must be registered and hold a Medical and Surgical qualification.

The appointment is subject to one month's notice, in writing, from or to the Board, and is tenable for an indefinite period from January 12th, 1930. Commencing salary £100 per annum, together with board and allowance for laundry.

Applicants must state age and qualifications and send twelve copies of their application and testimonials to the undersigned by Thursday, January 2nd, 1930.

By Order,
FRANK G. HAZELL,
December 13th, 1929. Gen. Supt. & Sec.

Manchester Royal Infirmary.

Remuneration is at the rate of £250 per annum, with board and residence.

Applicants must state age, and send twelve copies of their application and testimonials to the undersigned by Thursday, January 2nd, 1930.

By Order,
FRANK G. HAZELL,
December 13th, 1929. Gen. Supt & Sec.

Royal Albert Hospital and Eye
INFIRMARY, DEVONPORT.

The post of SENIOR HOUSE SURGEON will be vacant on January 1st, 1930. Applicants must be fully qualified, registered, and unmarried. Salary £150 per annum, with apartments, board, and laundry free.

Applications, together with copies of not more than three testimonials (which will not be returned), addressed to the "Chairman of the Selection Committee," must reach the undersigned not later than first post Tuesday, December 31st.

FRANK ROWE,
December 13th, 1929. Secretary.

Borough of Walthamstow.
EDUCATION COMMITTEE.

APPOINTMENT OF SCHOOL DENTIST (Man or Woman).

The Education Committee invite applications for the position of School Dentist at a commencing salary of £500 per annum, rising by annual increments of £25 to £650 per annum.

Candidates must be registered and qualified Dentists, and preference will be given to applicants who also possess qualifications in Medicine and Surgery. *Age must not exceed* 40 years.

The successful candidate must devote the whole of his or her time to the duties of the office, and will be required to pass a medical examination by the School Medical Officer, under whose general supervision he or she will act.

The Local Government and Other Officers Superannuation Act, 1922, will come into operation on April 1st, 1930.

Applications, stating age, with particulars of training, experience, and qualifications, and accompanied by copies of *three recent testimonials*, must reach the undersigned not later than Friday, December 27th.

Education Offices, 263, High St., E.17. December 9th, 1929. S. W. BURNELL, Director of Education.

Parish of Coventry.
ASSISTANT MEDICAL OFFICER.

The Guardians of the Parish of Coventry invite applications for the appointment of Assistant Medical Officer at the GULSON ROAD HOSPITAL and LONDON ROAD INSTITUTION, COVENTRY.

The salary will be at the rate of £200 per annum, and until residential accommodation can be provided at the Hospital an additional residential allowance of £150 per annum will be paid. For the present, the candidate appointed will be required to reside outside but within reasonable proximity to the Hospital, and subject to the approval of the Guardians.

Candidates must be single men, and the candidate appointed will be required to devote the whole of his time to the duties of the office, and to act under the directions of the Resident Medical Officer.

The appointment will be subject to the *approval of the Minister of Health* and to the provisions of the Poor Law Officers Superannuation Act, 1896.

Forms of application may be obtained from the undersigned, and completed applications should be returned as early as possible.

Guardians' Offices, *13, Little Park St.*, Coventry. December 11th, 1929. E. A. EVANS, Clerk to the Guardians.

Bolton Union.

The salary will be at the rate of £225 per annum, and rations, furnished apartments, attendance, washing, etc.

The Hospital has accommodation for 350 patients, is a recognized training school for nurses, and has a Medical Superintendent and three resident Assistant Medical Officers.

Forms of application, together with conditions of appointment (for which a stamped addressed foolscap envelope *must be enclosed*), may be obtained from me.

Last day for applications January 6th, 1930.
28, *Mawdsley St.*, Bolton. December 13th, 1929. *H. I. COOPER*, Clerk to the Guardians.

The London Female Lock
HOSPITAL,
283, Harrow Road, London, W.9.

The Board of Management invite applications for the appointment of HOUSE SURGEON (male or female) at the Female Lock Hospital. Salary at the rate of £150 per annum, with furnished rooms, full board, and washing. Candidates, who must be doubly qualified and duly registered, should *send in their applications* by January 6th, 1930, accompanied by copies of three recent testimonials, to the Secretary, from whom further particulars can be obtained. The appointment is for six months commencing February 12th.

Lowestoft and North Suffolk
HOSPITAL, LOWESTOFT.

JUNIOR HOUSE SURGEON (male) required. Salary £120 per annum, with board, residence, and laundry. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

Nottinghamshire County Council
EAST RETFORD CORPORATION.
EAST RETFORD RURAL DISTRICT COUNCIL.

APPOINTMENT OF JOINT MEDICAL OFFICER.

The Nottinghamshire County Council, the East Retford Corporation, and the East Retford Rural District Council jointly invite applications from duly qualified and registered Medical Practitioners for the whole-time appointment of a Medical Officer to act as—

(*a*) ASSISTANT MEDICAL OFFICER of the County Council;

(*b*) MEDICAL OFFICER OF HEALTH, SCHOOL MEDICAL OFFICER, and CERTIFYING OFFICER for the purposes of Section 55 of the Education Act, 1921 (Defective and Epileptic Children), and Section 31 (1) of the Mental Deficiency Act, 1913, of the Corporation of East Retford;

(*c*) MEDICAL OFFICER OF HEALTH to the East Retford Rural District Council.

The salary attaching to the position will be £750 per annum (with reasonable travelling and subsistence allowances), rising after two years' satisfactory service by two annual increments of £25 each to a maximum of £800 per annum; and the person appointed will be required to reside within a radius of two miles from the Market Square, East Retford.

Applicants must have had at least three years' professional experience since qualifying, be conversant by experience in the duties of a Medical Officer of Health and School Medical Officer, and also possess a Diploma in Public Health. Experience in Refraction Work and the examination of Defective Children is essential.

The appointment will be terminable on three months' notice, and be subject to the approval of the Ministry of Health and the Board of Education, and also to the provisions of the Sanitary Officers Order, 1926.

Form of application and conditions of appointment can be obtained at my office, and must be forwarded to me not later than December 30th, 1929.

K. TWEEDALE MEARY,
Clerk of the Nottinghamshire
Shire Hall, County Council.
Nottingham, Dec., 1929.

County Borough of Great YARMOUTH.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT TUBERCULOSIS OFFICER.

Applications are invited for the position of Assistant Medical Officer of Health and Assistant Tuberculosis Officer. Salary £600 per annum.

The gentleman appointed will be required to devote the whole of his time to the service of the Corporation, and in addition to acting as Assistant Tuberculosis Officer will be required to assist in the general work of the Health Department, working for all purposes directly under the Medical Officer of Health, who is also Tuberculosis Officer.

Candidates must have had at least three years' experience of their profession since qualification; be able to show special experience in the diagnosis and treatment of tuberculosis; and should hold a Diploma in Public Health.

The appointment is subject to the approval of the Ministry of Health and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, stating age, marital state, qualifications, tuberculosis experience, and general experience together with not more than three recent testimonials, should be delivered to the Medical Officer of Health, Town Hall, Great Yarmouth marked "Assistant Medical Officer," not later than January 4th, 1930.

Dated this twelfth day of December, 1929.

Town Hall, W. EDGAR STEPHENS,
Great Yarmouth. Town Clerk.

The General Hospital, BIRMINGHAM.

Applications are invited for the following resident appointments from January 15th, 1930:

HOUSE PHYSICIAN. Salary £70 per annum.

HOUSE SURGEONS (Three). Salary £70 per annum.

Applications, giving full details of qualifications and accompanied by testimonials (if desired), should reach the undersigned by December 30th.

A. H. LEANEY, House Governor.

West Suffolk General Hospital, BURY ST. EDMUND'S. (108 Beds.)

Applications are invited for the post of HOUSE SURGEON (male), which will be vacant early in January. Salary £150 per annum, with board, residence, and laundry. Applicants must be fully qualified and registered.

Applications, giving particulars of experience and enclosing three recent testimonials, to be sent to the undersigned.

E. E. HARDWICKE,
December 9th, 1929. Secretary.

Lancashire County Council.
SCHOOL MEDICAL AND CHILD WELFARE DEPARTMENT.

APPOINTMENT OF ASSISTANT COUNTY MEDICAL OFFICER.

The Lancashire County Council invites applications from registered Medical Practitioners for the post of Assistant County Medical Officer.

Applicants must not be over 35 years of age, and must possess the Diploma of Public Health.

The duties of the post include the Medical Inspection of School Children; work under the Maternity and Child Welfare Acts; general Public Health work; and such other duties as may from time to time be imposed by the County Council.

The person appointed will be required to devote his whole time to the service of the County Council. The salary will be £830 a year, rising (subject to satisfactory service) by annual increments of £50 to a maximum of £1,030 a year, together with first-class railway fares and other reasonable expenses.

The person appointed will be required to pass a medical examination, and to contribute to the Council's Superannuation Fund.

Applications must be made upon a form which can be obtained, together with further particulars, from the County Medical Officer of Health, School Medical and Child Welfare Department, *County Offices, Preston, to whom* the completed forms should be returned not later than Tuesday, December 31st, 1929. All communications must be endorsed "Assistant County Medical Officer."

Any form of canvassing is strictly forbidden, and will disqualify.

GEORGE ETHERTON,
Clerk of the County Council.
County Offices, Preston,
December, 1929.

Wilts County Council.

APPOINTMENT OF ASSISTANT SCHOOL DENTIST.

The Wilts County Council invite applications for the appointment of an Assistant School Dentist, to work in the Department of the County School Medical Officer, at a salary of £450 per annum.

Subsistence allowance in accordance with the County scale will be paid.

The officer appointed must be duly qualified and registered, and will be required to reside in or near Trowbridge.

The appointment will be made subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, and accompanied by copies of not more than three recent testimonials, must be delivered in envelopes marked "School Dentist," not later than the first post on Friday, January 3rd, 1930.

Canvassing, either directly or indirectly, will disqualify.

County Offices, W. L. BOWN,
Trowbridge, Wilts. Clerk of the
December 10th, 1929. Council.

Swansea County Borough.

MALE ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite applications from duly qualified Medical Practitioners for the post of Male Assistant Medical Officer to assist with the Medical Services of the Corporation.

Hospital resident and special experience of refraction and ear, nose, and throat work, school medical service, and maternity and child welfare experience, are desirable; the D.P.H. qualification, if additional to the foregoing, is also desirable. Salary £60 per annum, subject to the approval of the Board of Education and the Ministry of Health.

Applications on special forms, which can be obtained from Dr. Thomas Evans, Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than December 31st.

Victoria Hospital, Burnley.

Wanted, HOUSE SURGEON (male), fully qualified. Appointment, six months. Salary £125 per annum, with board, lodgings, and washing. Applications may be sent in at once to F. A. HARGREAVES, Hon. Secretary, 7, Grimshaw Street, Burnley.

N.B.—This Hospital is approved by the London University for the M.B. and M.S. Examinations.

Birkenhead & Wirral Children's HOSPITAL, Woodchurch Road.

HON. DENTAL SURGEON. There is a vacancy at the above Hospital. Applications, together with copies of testimonials, to be sent addressed to the Secretary, at the Hospital, not later than December 31st.

Manchester Union.

ASSISTANT MEDICAL OFFICER.

The Guardians of the Manchester Union invite applications from Medical Practitioners, who have had previous resident Hospital experience, for the following appointments:

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER at the WITHINGTON HOSPITALS (1,200 beds) and INSTITUTION (1,150 beds), Nell Lane, West Didsbury, Manchester; and

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER at the CRUMPSALL INFIRMARY (1,300 beds) and INSTITUTION (1,600 beds, including 600 beds for Mental Patients), Crescent Road, Crumpsall, Manchester.

The Hospitals and the Infirmary are recognised Training Schools for Nurses and are equipped with all modern Hospital requirements.

The appointments are entirely separate and the salary for each will be at the rate of £275 per annum, with rations and furnished apartments, subject to the usual deductions under the Poor Law Officers Superannuation Act, 1896.

The successful candidates will be required to commence duty on March 1st, 1930.

Applications, endorsed "Medical Appointment," stating at which establishment—*Withington or Crumpsall*—an appointment is desired, accompanied by not less than three testimonials, must reach me not later than Tuesday, December 31st instant.

Candidates desiring to apply for more than one appointment must send in a separate application in respect of each Hospital.

By Order,
Union Offices, F. W. GREENHALGH,
All Saints, Clerk to the
Manchester. Guardians.
December 12th, 1929.

Manchester Union.
BOOTH HALL INFIRMARY FOR CHILDREN.

ASSISTANT MEDICAL OFFICERS.

The Guardians of the Manchester Union invite applications from Medical Practitioners, who have had previous resident Hospital experience, for the appointments of Junior Resident Assistant Medical Officers (Third and Fourth) at the Booth Hall Infirmary for Children (750 beds), Charlestown Road, Blackley, Manchester.

The Hospital is a recognised Training School for Nurses and is equipped with all modern Hospital requirements.

The salary for one appointment is at the rate of £275 per annum, and for the other at the rate of £250 per annum, with rations and furnished apartments, subject to the usual deductions under the Poor Law Officers Superannuation Act, 1896.

The successful candidates will be required to commence duty about February 1st next.

Applications, endorsed "Medical Appointment," Booth Hall Infirmary," accompanied by not less than three testimonials, must reach me not later than Tuesday, December 31st inst.

By Order,
Union Offices, F. W. GREENHALGH,
All Saints, Clerk to the
Manchester. Guardians.
December 12th, 1929.

WATFORD HERTS

AN ANTITOXIN OF OUTSTANDING MERIT

Streptococcus Antitoxin (Scarlatina)

PARKE, DAVIS & CO.

Scarlet Fever Streptococcus Antitoxin, Concentrated (Globulin), P., D. & Co.

THIS antitoxin, prepared according to a method perfected in the Research Laboratories of Parke, Davis & Co., is independently tested by the Drs. Dick (by arrangement with the Scarlet Fever Committee of America), and the strength of the antitoxin is expressed in terms of the unit formulated by them.

¶ In the manufacture of the P., D. & Co. product an attempt is made to render it actively antibacterial as well as antitoxic. The object is to obtain a preparation that will not only be capable of neutralising the toxæmia but will also exert a direct action on the infectious processes.

¶ In the treatment of scarlet fever the contents of one bulb (a therapeutic dose) of Streptococcus Antitoxin (Scarlatina), P., D. & Co., is generally sufficient to bring about a marked drop in temperature and pulse rate, and only in rare instances does it appear to be necessary to administer a second dose. Provided the antitoxin is administered within the first three or four days of the disease the results are said to be even more dramatic than those effected with diphtheria antitoxin in the treatment of diphtheria.

Supplied in bulbs containing one therapeutic dose or one prophylactic dose (for temporary immunity). Further details of this preparation and of Scarlet Fever Streptococcus Toxin, for preventive immunization, will be sent on application.

BRAND

SANDOZ

Felamine, an association of the most powerful cholagogue — pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, provides a rational and effective treatment of biliary lithiasis, cholangitis, hepatitis, icterus, and all the symptoms of biliary insufficiency.

Felamine contains no accessory drugs. The cholagogic active principle (cholic acid) is present in an absolutely pure state, free from useless and harmful bile substances.

Indications.

Cholangitis, Cholecystitis, Hepatic Insufficiency, Hepatic Congestion, Jaundice, Chronic Constipation.

Felamine is supplied in Bottles of 50 and 250 Tablets at **5**/- *and* **20**/-

PUBLISHED DURING 1929

SAUNDERS BOOKS

PUBLISHED DURING 1929

DISEASES OF NOSE, THROAT, AND EAR — JACKSON & COATES
By 75 Authors. Edited by CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., and GEORGE MORRISON COATES, M.D., A.B., F.A.C.S. Assisted by CHEVALIER L. JACKSON, A.B., M.D. Octavo of 1,177 pages, with 657 illustrations, and 27 inserts in colours. Cloth, 60s. net.

MINOR SURGERY — CHRISTOPHER
By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery, Northwestern University Medical School, Chicago. With a Foreword by ALLEN B. KANAVEL, M.D., F.A.C.S. Octavo of 694 pages, with 600 illustrations. Cloth, 36s. net.

PHYSICAL THERAPEUTIC TECHNIQUE — GRANGER
By FRANK BUTLER GRANGER, A.B., M.D., Late Physician-in-Chief, Department of Physical Therapeutics, Boston City Hospital. With a Foreword by WILLIAM D. MCFEE, M.D. Octavo of 417 pages, with 135 illustrations. Cloth, 30s. net.

CLINICAL ELECTROCARDIOGRAMS — WILLIUS
By FREDERICK A. WILLIUS, B.S., M.D., M.S. in Medicine, Section on Cardiology, The Mayo Clinic, Rochester, Minn. Quarto volume of 219 pages, with 368 electrocardiograms. Cloth, 36s. net.

THE NEUROSES — WECHSLER
By ISRAEL S. WECHSLER, M.D., Associate Professor of Clinical Neurology, Columbia University, New York City. Octavo of 330 pages. Cloth, 18s. net.

COLLECTED PAPERS OF 1928 — MAYO CLINIC
By WILLIAM J. MAYO, M.D., CHARLES H. MAYO, M.D., and their ASSOCIATES at the Mayo Clinic, Rochester, Minn., and the Mayo Foundation, University of Minnesota. Octavo of 1,197 pages, illustrated. Cloth, 60s. net.

PUBLIC HEALTH AND HYGIENE — BOLDUAN
By CHARLES FREDERICK BOLDUAN, M.D., Director, Bureau of Health Education, Department of Health, City of New York. 12mo. of 312 pages, illustrated. Cloth, 12s. 6d. net.

THE VOLUME OF THE BLOOD AND PLASMA — MAYO CLINIC
By LEONARD G. ROWNTREE, M.D., and GEORGE E. BROWN, M.D., of the Mayo Clinic, Rochester, Minn. 12mo. of 219 pages, with 17 illustrations and 47 tables. Cloth, 14s. net.

PHYSICAL DIAGNOSIS OF CHEST DISEASES — NORRIS & LANDIS
By GEORGE W. NORRIS, M.D., Professor of Clinical Medicine, University of Pennsylvania, and H. R. M LANDIS, M.D., Sc.D., University of Pennsylvania. With a chapter on the Electrocardiograph in Heart Disease by EDWARD B. KRUMBHAAR, M.D., Philadelphia General Hospital. Octavo of 954 pages, with 478 illustrations, some in colour. Fourth Edition, thoroughly revised. Cloth, 45s. net.

HISTORY OF MEDICINE — GARRISON
By FIELDING H. GARRISON, M.D., Lieutenant-Colonel Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other illustrations. Fourth Edition. Cloth, 55s. net.

ILLUSTRATED MEDICAL DICTIONARY — DORLAND
By W. A. NEWMAN DORLAND, M.D., Member of the Committee on Nomenclature and Classification of Diseases, American Medical Association. Octavo of 1,427 pages, with 525 illustrations, 105 in colours. Fifteenth Edition. Flexible binding, 35s. net.

SURGICAL PATHOLOGY — BOYD
By WILLIAM BOYD, M.D., M.R.C.P.Ed., F.R.S.Can., Professor of Pathology, University of Manitoba. Octavo of 933 pages, with 476 illustrations, and 15 coloured plates. Second Edition. Cloth, 48s. net.

NOSE, THROAT, AND EAR — GLEASON
By E. B. GLEASON, M.D., LL.D., Professor of Otology, Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania. 12mo. of 617 pages, illustrated. Sixth Edition. Cloth, 21s. net.

PREVENTION OF DISEASE IN THE INDIVIDUAL — WINSLOW
By KLAELM WINSLOW, B.A.S., M.D., Attending Physician to Seattle City Hospital and King County Hospital, Washington. 12mo. of 431 pages, illustrated. Third Edition. Cloth, 12s. 6d. net.

WRITING OF MEDICAL PAPERS — MELLISH-WILSON

"EUMENTHOL JUJUBES" (HUDSON)

Made in Australia.

HARMFUL THROAT TABLETS. Throat Tablets and Lozenges containing Formalin (Formaldehyde) are harmful. Wiley, of the United States, investigated the effects of small doses of Formalin (Formaldehyde) given with milk, on 12 men during 15 days. Burning in the throat, itching rash, and loss of body weight were observed.—*Vide* Martindale. All countries which have made legal enactments and laws regarding the purity of its food supply have prohibited the addition of Formaldehyde (Formalin) as a preservative of food. HUDSON'S EUMENTHOL JUJUBES contain no Formalin, Cocaine, or other harmful or poisonous drug. Sold everywhere.

FREE SAMPLES forwarded to Physicians on receipt of professional card by F. NEWBERY & SONS, Ltd., 31-33, Bunner St., London, E.C.1. DUNCAN FLOCKHART & Co., Agents, Edinburgh, Scotland.

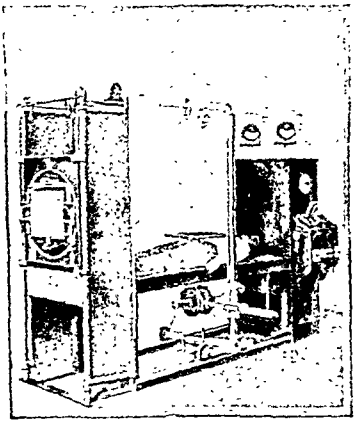
A. E. DEAN & CO.

Makers of all types of X-Ray and Electro-Medical Apparatus of the Highest Grade.

LEIGH PLACE, BROOKE STREET, HOLBORN, LONDON, E.C.1

Showrooms: 14, BALDWIN'S GARDENS—adjoining.



PRICE complete, as illustrated, for use on Alternating Current, including all Accessories £350

Ditto, Apparatus for use on Direct Current £410

The outfit can be supplied with Metalix X-Ray tube instead of Coolidge X-Ray tube at an additional charge of £10.

SEND FOR DESCRIPTIVE CATALOGUE No. E40.

Now available for every Hospital.

The acme of Simplicity.

The NINETY-THIRTY **X-RAY APPARATUS**

Certified by NATIONAL PHYSICAL LABORATORIES as complying with RECOMMENDATIONS OF THE X-RAY COMMITTEE ON PROTECTION.

The power of the apparatus here shown is 90 kilo-volts at 30 milliamperes and is therefore capable of meeting the requirements of any hospital for diagnostic radiography and fluoroscopy.

The floor space occupied by the complete installation is only 9 ft. × 2 ft. and is therefore suitable for any X-ray room.

The operation of the outfit is so simple that any doctor can obtain radiograms of first-class quality even though he may have had no previous experience. The difficulties associated with X ray work in the past are now entirely overcome by a device known as the "Automatic Technique Director" which indicates the exact setting of the controls for radiographing any part of the body. The outfit includes a full set of accessories, dark room equipment, etc., and thus COMPRISES A COMPLETE INSTALLATION.

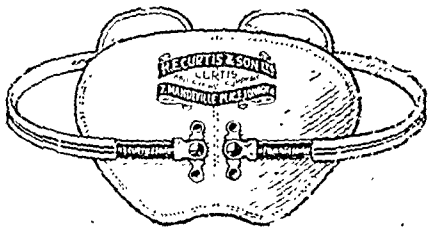
THE Immediate delivery from stock. Sole Manufacturers:

MEDICAL SUPPLY ASSOCIATION, Ltd.

The largest X-Ray and Electro-Medical Showrooms in the British Empire.

167-185, GRAY'S INN ROAD, LONDON, W.C.1. *Telephone: Terminus 5132*

THE CURTIS ABDOMINAL SUPPORT
MODEL No 1
FOR EFFICIENCY



The principle of the Curtis Abdominal Support, Model No. 1, is based on a direct anterior *posterior pressure*, a principle which affords very considerable advantages over any abdominal belt or support yet available.
The only support giving direct abdominal uplift; there is no cramping or binding of the hips, whilst a constant uplifting *pressure* is maintained in any assumed position. There are no complicated fastenings; one strap and buckle suffices.
Made of metal, it has a much longer life without being heavier.

For full particulars apply to:—

GRAMS CURTIS MAYFAIR 1608 — H. E. CURTIS & SON LTD. — PHONE MAYFAIR 1608-9

(Sole Manufacturers of the Curtis Appliances),

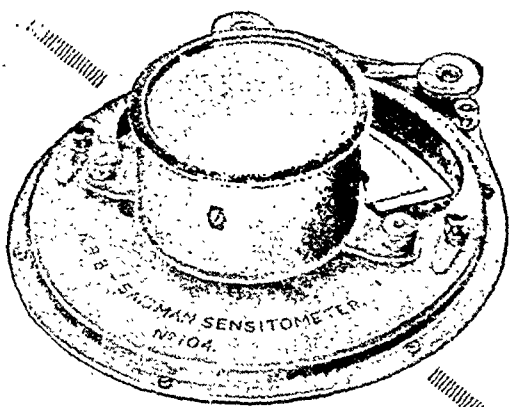
7, MANDEVILLE PLACE,
WIGMORE STREET, W.1

The

K.B.B.

SAIDMAN SENSITOMETER

This New Sensitometric Test of
Dr. JEAN SAIDMAN,
Director of the Institut D'Actinologie, Paris, introduces a Rational Method of Treatment in Actinotherapy.



BRITISH MODEL.
Price, complete in case with supply of test masks
£4 . 4 . 0

1. It supersedes the old *empirical* methods.
2. Gives the sensitivity and correct dosage factor of the patient before treatment.
3. Avoids overdosage and attendant reactions.
4. Ensures the maximum of good results.

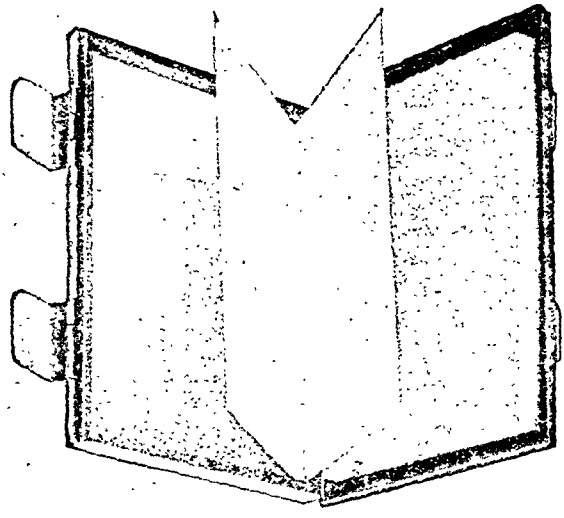
Manufactured by:

KELVIN, BOTTOMLEY & BAIRD, LTD.,
18, Cambridge Street GLASGOW. C.2.
Imperial House, 80/86, Regent Street, LONDON, W.1.
(Showroom Entrance in Air Street).

Also Manufacturers of full range of Quartz Mercury Vapour Lamps for Light Therapy.

The late Lord Kelvin, Chairman, 1900-1907.

"Kodak"
Metal X-Ray Cassette



Simple and efficient.

The convenient book-form and absence of heavy back spring makes loading and unloading exceedingly simple.

Effective contact is ensured.

Kodak Limited (Medical Dept.)
Kingsway, London, W.C.2.

A special food for changing the intestinal flora

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of its slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3.

LACTO-DEXTRIN

Manufactured by the BATTLE CREEK FOOD CO., Mich., U.S.A.

FOR INTERNAL TREATMENT OF

GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal-Wood, the oil is bland and remarkably **FREE FROM THE IRRITANT AND NAUSEATING EFFECTS** which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2.

Physicians are invited to send for Clinical Reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

JB 97

In the Treatment of

Chronic Infections

The primary use of Contramine is still in the treatment of gonorrhœa with chronic complications.

Contramine is, however, also of proved value in cases of chronic rheumatism, arthritis, and fibrositis; in fact, even very stubborn cases which have failed to respond to prolonged treatment with other drugs are often benefited very considerably as a result of a course of Contramine treatment.

Contramine is issued in ampoules of 1 c.c. and 2 c.c. containing the drug in sterilised isotonic solution ready for intramuscular injection.

Ideal Food for the Sick.

Agreeable, highly Diffusible, Assimilable.

The patient or the nurse may stretch out a hand at any time, in the night or any daylight hour, and find in Panopepton a stimulating, fortifying food, especially "heartening." It more quickly and substantially relieves that "gone feeling" than anything else we know of.

Panopepton is obtained by the physiological hydrolysis of the entire wheat berry and prime lean beef.

The original thought in Panopepton, fully realised, is that it shall present for the invalid the complex of nutritive material which only may be derived under the most favourable conditions of digestion.

Panopepton presents a complex of proteins now known to be essential, and for the greater part in the form of nitrogenous, non-coagulable proteins, all the extractives, savory and mineral substances of the prime lean beef and entire wheat berry; the wheat carbohydrates in the form of dextrose and maltose.

All these considerations are significant in connection with the observations frequently made as to the remarkably stimulating and restorative effects of Panopepton.

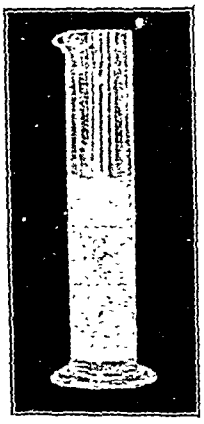
"Allenburys" The DIET

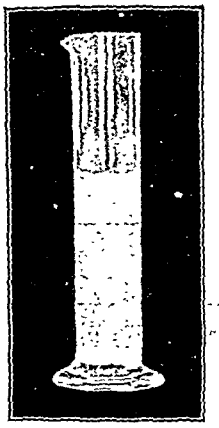
A Stimulating and Sustaining Food Beverage

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive literature and free clinical sample will be gladly sent on request

ALLEN & HANBURYS LTD., Bethnal Green, London, E.2.

VITAD PALATINOIDS

¶ VITAD is the unsaponifiable fraction of Cod-Liver Oil containing in a high concentration Vitamins A and D.

¶ While presenting practically the full medicinal properties of Cod-Liver Oil, it is free from the nauseating oily fraction. Being exhibited as a Palatinoid, it is protected by the hermetically sealed non-actinic covering from all chance of oxidation and light action, thus ensuring a standard dose at all times.

¶ Palatinoid Vitad is put up in bottles of 25 and 100, and in two strengths:

m. 1½ for Children
m. 3 for Adults.

Two palatinoids respectively represent the full daily dose of Vitamins A and D.

Roboleine
The Food that Builds the Body

Manufacturers of Roboleine.

OVALTINE

MILK AND ITS DEFICIENCIES.

In the dietary of fevers and infectious diseases milk probably holds the most important position for one reason, that it leaves a residue which is not mechanically irritating.

Milk, however, has certain objections. It is deficient in carbohydrate; it is also repugnant to many people and rapidly becomes tiresome to others.

"Ovaltine" improves milk as a nutritional agent wonderfully. It relieves the monotony of a milk diet. Further, the addition of "Ovaltine" to milk not only makes it more attractive to the taste, but raises the nutritive power and renders the milk twice as digestible—valuable features where dyspepsia is associated with constitutional disturbance.

"Ovaltine" adjusts the carbohydrate deficiency in cow's milk and converts the curd into a light, flaky, easily digested coagulum. It also provides nutriment of inestimable value for maintaining adequate nutrition

A liberal trial supply will be sent to members of the medical profession in private or hospital practice.

BY APPOINTMENT

NEARLY A CENTURY OF ACHIEVEMENT LIES BEHIND THEIR MAKING

THE exclusive process known only to Brand & Company of extracting their essences was first evolved nearly a century ago by Mr. Brand in collaboration with a celebrated physician.

The valuable restorative and stimulating properties of these essences were immediately recognized by the Medical profession which has prescribed them ever since.

When appetites are failing and patients are reluctant to eat, Brand's Essences promote appetite. For by stimulating the gastric juices they prepare the patient for more solid diet.

By a special process Brand's Essences are made entirely of the pure juices from freshly killed meats.

Brand's Essences (Beef, Mutton and Chicken) can be obtained throughout the world at chemists and stores in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES

(BEEF & CHICKEN)

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

PNEUMONIA

Prevention and Treatment

PNEUMOCOCCUS ANTIBODY SOLUTION MULFORD is an aqueous solution of active immune bodies extracted from Antipneumococcic Serum Types I., II., and III. combined. It is practically free from horse serum protein, therefore there is no danger of anaphylaxis or serum sickness, and being a watery solution, it is very soluble in the body fluids and is quickly absorbed. In 50 cc. vials.

ANTIPNEUMOCOCCIC SERUM POLYVALENT TYPES I., II., and III. COMBINED is obtained from horses injected with cultures of Types I., II., and III. of the pneumococcus. It is fully equivalent to the Type I. Serum in its protective power against pneumonia caused by Type I., and also contains antibodies that will protect against Types II. and III. In 10, 20 and 50 cc. vials.

ANTIPNEUMOCOCCIC SERUM TYPE I. is sometimes preferred when time and circumstances permit of a diagnosis, including type determination. In 50 cc. vials.

PNEUMO-SEROBACTERIN MIXED.—The value of Bacterial Vaccines for prophylactic and therapeutic use in pneumonia and in preventing pulmonary complications following influenza, etc., has met with considerable success. May be employed alone or as an adjunct to Serum treatment, stimulating the effect of antibodies to neutralise the effects of the invading bacteria.

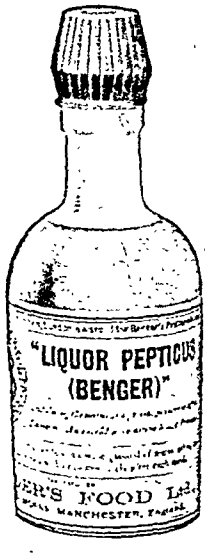
ESSENCE of RENNET

CONCENTRATED (BENGER).

(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding. As it is concentrated it is much quicker in its effect than most other preparations of Rennet. Whey prepared with Benger's Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc.; it can be employed with confidence and will yield good results. Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles.
Larger sizes for hospitals, etc., use.



LIQUOR PEPTICUS

(BENGER).

"A digestive agent of extraordinary power."
Sir William Roberts, M.D., F.R.S.

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods.

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone. Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected.

In 4, 8 and 16-oz. bottles.
Prices: 3/6, 6/6 and 12/6.

SPLEEN SOL.N
in the Treatment of
ECZEMA & URTICARIA

Dr. Thos. M. Paul of St. Joseph's, Missouri, in "The Urologic and Cutaneous Review," Vol. XXXIII, No. 11, 1929, states in the opening paragraph:—

"To state that hives will disappear in fifteen minutes, that the itching and oozing of an eczema will cease in half an hour, and that an eczematous lesion, regardless of its degree of lichenification, will vanish in a few days, as the result of a hypodermic injection, seems preposterous, yet such has been the writer's experience in a series of sixty-one cases."

We have these ampoules available for immediate despatch, and a few copies of the actual article for loan to interested Dermatologists.

COW & GATE MILK FOOD.
Always less than 150
Bacteria per c.c.

BACTERIOLOGY of MILK

Bacteriological sterility is perhaps one of the most important desiderata in the feeding of Infants. Periodical outbreaks of milk-borne epidemics are evidence enough that raw liquid milk is still outside the pale of safety; and the continual presence of tubercle bacilli in milk renders some form of treatment essential.

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

The accompanying micro-photographs illustrate the comparative degree of purity of different grades of milk and are convincing proof of the reliability of Cow & Gate Milk as opposed to all other forms of milk.

The bacteriological purity of Cow & Gate is assured by an Improved Roller Process which, unlike other forms of heat treatment, involves a minimum exposure to heat, and preserves intact the natural and rich vitamin content of the original West Country milk.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

ONE OF THE GREAT ART TREASURES OF CHINA.—The design here reproduced from a memorial pillar to "Shên" has an inscription consisting of four ideographs surmounted by a fine figure of a phœnix. This magnificent design is full of nervous energy and strength. The written characters themselves are highly decorative—the Chinese have always looked upon writing as a branch of art.

The art of a country is perhaps the best index to its civilisation. Although the civilisation of China has sometimes stagnated for long periods, we know that during the Han epoch it progressed and reached a general level equal to that of ancient Greece and Rome. That this fact has not been realised is due to its essential difference and to its existence being unknown until modern times. At times during this 400 years, empire-building and internal development of the state were conducted with great vigour and an enlightened policy. In art, China has always been subject to many influences from without, and these she has absorbed and applied, without, however, being led away from her own characteristic features and principles, which can be traced back continuously to very remote times. In like manner, China's civilisation has the distinction of having run its course with continuity for about 4000 years: it is the oldest extant.

Remarks
ON
THE STUDY AND TEACHING OF PAEDIATRICS.*

BY
LEONARD FINDLAY, M.D.,
PROFESSOR OF PAEDIATRICS, UNIVERSITY OF GLASGOW; PHYSICIAN ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

WHEN Professor Joanovitch, Dean of the Faculty of Medicine, along with the President of the Jugoslavian Medical Association, did me the signal honour of inviting me to address my Serbian colleagues, I had considerable difficulty in deciding on a theme. There are very many subjects on which an interchange of our views would be of mutual benefit and interest. However, I ultimately decided that it might be of more general interest to the medical faculty of Belgrade if I were to say something regarding the teaching and study of that branch of medicine to which I have devoted most attention.

Paediatrics not a Speciality.

You will notice that I have spoken of it as a branch of medicine. I used this phrase advisedly, because I did not wish to employ the word "specialty" so often adopted when referring to the subject. Paediatrics, or diseases of children, I protest most emphatically is not a specialty. A specialty suggests the study of a particular organ of the body—as, for example, the eye or the ear—or a special method of treatment of disease—for example, surgery or electro-therapeutics—but paediatrics is general medicine practised during the earlier, and one might make bold to remark the most important, years of life, at least so far as prophylaxis and cure are concerned. The true and ideal paediatrician is a general physician with a full knowledge of disease at a certain period of life, just as a neurologist is a general physician who has paid particular attention to diseases of the nervous system.

Disease Influenced by Many Factors.

Disease is influenced by many factors—for example, environment, climate, age, and sex—and he who only considered one factor would have a narrow outlook of his subject. Certain diseases, such as developmental errors, it must be admitted are peculiar to infancy and childhood: but even in this field of clinical pathology age is not an absolutely sharply differentiating feature, because some varieties of the condition—for example, aneurysm and morbus cordis (cyanose tardive)—may not declare their presence until adolescence or adult life. Some diseases are specially prone to occur during infancy and childhood; in fact, so much more commonly do they happen during the early years of life, that the adjective "infantile" is almost invariably prefixed. "Infantile paralysis" is a good example, as also is "infantile diarrhoea," which, at least in Britain, is a synonym for epidemic diarrhoea—British cholera—acute gastro-enteritis and intoxication of Finkelstein. Other diseases, again, occur at all ages, but vary so much in their manifestations at the different periods of life that they are looked upon, or at least have until recently been looked upon, as quite different pathological entities. Rickets and osteomalacia are the conditions which in this connexion I have in mind. It is simply because the diseased process is occurring during the period of growth in the one case and after growth is complete in the other that such different pictures are produced. It is possible, as Dr. Harry Hutchison, who worked in my department, has shown, to trace all gradations—from typical infantile rickets, through late rickets occurring in older children and adolescents, to osteomalacia in the fully grown adult.

Medicine cannot be divided into compartments according to whether the patient is 5 years of age or 50 years of age. The same disease affects all ages of man, and in order to have a true appreciation of that disease it is essential for us to study it under all conditions. In Berlin, where specialization had run riot, at least before the war, I knew doctors who from the day of graduation had never seen a patient of greater age than 1 year; and in America and in England, too, there is a tendency to follow along similar lines. Nor can we satisfactorily classify our patients according to which organ is apparently involved, and relegate the diagnosis of disease to this or that specialist. Yet patients are wont to choose their medical attendant according to whether their discomfort is in their head or their heels, a practice which we know is often fraught with disaster. The whole body works in harmony, and we know only too well that though the disease may be situated in one viscus, the symptoms are referred to another.

The Specialization of Disease: Is it Detrimental to the Medical Student?

Of late there has been a tendency to go even further astray in the specialization of disease and to limit attention to the study of the effects of one particular micro-organism, I am, of course, referring to tuberculosis and venereal disease. If ever there were conditions which have demanded a general knowledge of disease for their full appreciation, and consequently for their proper treatment, and which are thus quite unsuitable for specialization, these conditions are tuberculosis and syphilis. How can a physician ever become satisfactorily acquainted with pulmonary tuberculosis and its diagnosis unless he has opportunities of seeing all varieties of mischief in the lung? Fortunately, in the case of syphilis there is a specific test to keep the physician on the right lines, but in the case of tuberculosis there is no such controlling factor, with the result that we are only too familiar with the diagnosis of tuberculosis when assuredly there is at least no active mischief present.

In the case of the child there is perhaps no more frequent mistake than the confusion of chronic pneumonia, with or without bronchiectasis, and pulmonary tuberculosis. I have often visited sanatoriums and have had healthy-looking, at least well-nourished, children shown to me as examples of pulmonary tuberculosis. I well remember having submitted to me a series of twelve children from a neighbouring sanatorium for the demonstration of chronic phthisis pulmonalis in the child. Not one single child, however, was suffering from pulmonary tuberculosis, but each was an example of unresolved or chronic non-tuberculous pneumonia. How is it possible for the physician to learn to differentiate between the various types of chronic pulmonary disease, and, what is of greater importance, to educate the student in their diagnosis, unless he has opportunities of observing them? Unfortunately for the student, and also for the teacher, there has grown up a custom in our general hospitals at home not to admit examples of pulmonary tuberculosis, so that there are two fields of study so far as disease of the lungs is concerned—one for tuberculous material and another for non-tuberculous—without any point of contact, and the differential diagnosis, at least in the student's mind, thus comes to depend more on the geographical situation of the patient than on the history of his illness and the physical examination of the chest. The educational loss to the student in this way is enormous. I consider it fortunate that neither I nor my medical colleagues at the Glasgow Children's Hospital believe that we are competent to diagnose with certainty in the receiving room of the hospital the tuberculous lung, so that much tuberculous material finds its way into our wards, and the students, as well as ourselves, benefit so far as our diagnostic acumen is concerned.

This artificial division of diseases into specialties may have brought about some little increase in knowledge, but it has not to any great extent been for the benefit of the individual patient, as it has narrowed the outlook of the family doctor, and, to my mind, has had a very serious effect on the teaching of the medical student. It may be argued that in the special department where the clinical material is concentrated the student gets the best opportunities of becoming acquainted with the particular disease, but I hold that he is being taught by a biased individual whose exposition will tend to be lop-sided and

* Abstract of a lecture to the Belgrade Faculty of Medicine and Medical Association, Jugoslavia, on the occasion of a visit to the Anglo-Serbian Children's Hospital, Belgrade.

reveal defective perspective, and the very real difficulty of differential diagnosis, as you and I meet with it in our daily work, will be insufficiently illustrated. In any case these special courses are of short duration and form a small fraction of the student's total clinical instruction. These objections are no idle theories, for, to judge from my contact with the final year medical student, this pernicious system is having a very detrimental effect on his outlook, and one cannot wonder at it. Without a Wassermann reaction, a barium meal, an electro-cardiogram, or an *x*-ray examination of the chest, the modern student seems unable to consider the pros and cons of a case, and cannot even hazard the likely diagnosis.

Thus you see that I consider as very ill-advised the attempt to split up general medicine into separate compartments or fields of study. By all means let each of us, as did the late Sir James Mackenzie and Sir Jonathan Hutchinson, choose one type of disease for special and intensive study, but in order that we may retain a sane outlook our survey of the physiological and pathological must be as wide as possible. Even in the academic field we find the same dangers of specialization. We have now in the domain of physiology the elevation of biochemistry into a separate field of study, so that the all-round physiologist is disappearing. In pathology, too, the divorce of histology and bacteriology, with the birth of the misnomer "pathological chemistry," will have a serious effect on our future teachers and students.

But, after all, the most important argument so far as diseases of children are concerned is the difficulty, in fact the absurdity, of speaking of the daily work of the family doctor as a specialty. Is it not true that children form the largest proportion of our patients, and hence if it is anything of a specialty it is one which every medical man must be expert in? There are some branches of work of which the average doctor sees so little that he cannot be expected to develop a special dexterity, but in his daily task, and the bulk of his daily task, who should be more expert?

One very serious consequence of the idea of paediatrics being a specialty would be that the unsatisfactory state which has up till now prevailed in our medical schools would be continued. From the day of our graduation it must have struck us all as almost Gilbertian that the very duties that in practice we are called upon most frequently to perform—the delivering of women and the care of children—were the very subjects on which we had obtained the least instruction. I do not deny that within the last fifty years there have been changes in the medical curriculum to meet the needs of the times. The subjects of pathology and public health have been introduced, and the teaching of chemistry and physiology has been revolutionized, but within the present century the clinical side of medical education has suffered, and until very recently the teaching of midwifery and diseases of children was really non-existent.

Prevention of Disease in Childhood.

In fact, medical education has simply been a reflection of the general outlook on the value of the child. It is difficult for us to-day to understand the long neglect of child life. We now see that the child is the best asset we have for the guarantee of a healthy future race, and that the cheapest way to treat much of the invalidism of the adult is to prevent the disease in the child—if I may be permitted to use what we at home call an Irishism. During the later years of last century it became appreciated that though the improvement in public health had brought about a great reduction in the general death rate the loss of infant life continued at the same high figure. As a result of these various considerations there has been a development of multifarious infant and child welfare schemes throughout the whole civilized world, and it is a moot point if they are being carried out as efficiently as they might be.

Unfortunately in our country the medical student has not been trained for this work, so that it has in great part been taken over by the health authorities and given into the hands of pseudo-specialists dealing with children under 1 year, and another group dealing with children from 5 to 14 years of age. Children from 1 to 5 years are at present not provided for. In any case we are developing the very class of specialists that I have deprecated. I can picture no more demoralizing sphere of work for one's medical outlook than to be condemned to do nothing but supervise healthy infants and direct their feeding. What medical philosophy can be built on such a foundation?

The right personnel for such schemes can only be recruited from the family doctors in the neighbourhood. They are engaged by the better classes to do this work, and surely they ought to be able to do it for the public authorities. Unfortunately, however, they have not been trained or introduced to this sphere of medicine, and it would seem that the average man or woman cannot pursue any line of study without preliminary instruction, and, further, unless he is examined on this training, that he will make little or no progress. Thus this branch of medicine must form an important part of the medical student's training.

The subject of infant feeding is perhaps the best example of the results of this want of education. In agricultural communities where life is simple the question of infant feeding is not so clamant, but in industrial countries like England it is one of great importance. On the Continent wet-nurses simplify it somewhat; but with us, where the wet-nurse is practically unknown, artificial feeding is the commonest occurrence, not because of bad habits, but from sheer inability of the mother to perform this natural function. As one who has many examples of nutritional diseases in infancy referred to him I have come to the conclusion that the average medical man is very ignorant of this subject. He has no general principles on which to base his practice. He simply chops and changes without rhyme or reason from one type of food to another, and while he appreciates that his motor-car will not go without petrol—or in other words food—he seems to think that the infant body, which not only must incessantly keep working but increase its size at the same time, will exist on air and water. A child cries because it is not getting enough; the the doctor concludes that it is the strength of the milk which is at fault and orders dilution; still cries from the baby and further retrenchment by the doctor until the child is only getting one or two ounces of milk in the day.

Study of Paediatrics by the Medical Student Essential.

How does such a state of matters arise? Simply because the doctor does not know the food requirements of the baby. This and such general principles of infant feeding have not formed a sufficiently prominent part of the medical curriculum, and yet it is no more complicated and no more difficult to learn than the rate of the pulse or respirations. In difficulty it cannot be compared with the physical examination of the chest.

In order that a student may be fitted to enter on medical practice it is essential that he learn how to examine a child. This I consider one of the most important lessons which the student must learn. The examination of a child requires an amount of tact and experience not necessary in the case of the adult. The adult, for the most part, can direct his physician's attention to his complaint, whereas all he may get from the child is a cry or a wail of pain. The child cannot tell his symptoms, and hence in this branch of medical practice physiognomy of disease is all-important. This can only be learned from prolonged study. The typical pictures of broncho-pneumonia, meningitis, pyogenic infection of the urinary tract, gastro-enteritis, scurvy, acidosis, and alkalosis all occur at once to the mind.

The physical examination of the child also requires special experience. The limits of the child are such that our examination should be carried out very gently, and any manipulations likely to cause pain should be performed last. Further, as all methods of examination applicable in the adult are likewise applicable in the child, but as the instruments are smaller and the fields of view more restricted, greater dexterity is necessary, and therefore more practice. Again, in diseases of children a knowledge of their life-history is of paramount importance. It is often possible, from the ungarnished story of the mother or the nurse about the behaviour of the child from the first

day he did not seem to be his usual self, to obtain the life-history of some malady exactly as described in our systematic textbooks. More mistakes in diagnosis of diseases in childhood are made through inattention to this point than to any other factor.

Educational Value to the Student of the Study of Paediatrics.

It is thus seen that the more study of diseases of children has an important educational value, and even on this ground alone paediatrics should be given a prominent place in the medical curriculum. By the study of paediatrics the student is bound to become more observant, more expert, not only in the use of those instruments with which he has been provided by nature, but also in the use of those which he has made for himself, and better acquainted with the life-history of disease because of the absolute necessity of this knowledge in the examination of the patient. Far from being one of the least studied branches of his work it should be one of the most studied.

If this decision regarding the value of paediatrics in the teaching of the medical student is accepted, then a very radical change in our medical course is necessary. I would not, of course, advise that the student be put right away to the study of disease in childhood. As I have already said, the limits of endurance of the child are sooner reached than in the case of the adult, and for the training in the elements of physical diagnosis the adult must still be the subject of election. It is only after the student has acquired a certain facility in the technique necessary for this purpose that he should be allowed to enter on the study of paediatrics.

Nursing of Sick Children.

What applies to the training of the medical man also applies to the complementary service in the treatment of the sick child—namely, the nurse. In English-speaking countries the nursing of sick children labours under a great disadvantage in that the training in a children's hospital does not count as that gained in a general hospital. In consequence, the staffing of a children's hospital is handicapped, and a sufficiency of nurses can only be obtained by enrolling women of a younger age than are eligible for the nursing of the adult. Thus it comes that girls of 18 are entrusted with the care of the sick child, although the same desiderata as were required by the physician are also necessary in her case—namely, greater powers of observation, greater dexterity in manipulations, and greater patience—the attributes that only come with experience. Instead of commencing her training in a children's hospital she should proceed, just as is advisable in the case of the medical student, from a training received in the adult.

Scheme for Training Medical Students.

I think I hear some of my audience saying that there can never be sufficient material for such a purpose—that our children's hospitals are not large enough, and certainly in my own town the children's hospital could not supply sufficient facilities for our hosts of students. But between the care of children and that of the adult there is one very radical difference. The treatment of any serious internal ailment in the adult cannot be ambulant, whereas this is eminently possible with regard to a great deal of disease in the child. The size of the patient makes it possible for him to be easily carried to and from the doctor. There is, too, a great disinclination on the part of many parents to allow their infants and young children to enter hospital, and it is often only in the case of infections, with resultant danger to the other members of the family, that these objections can be overcome. Hence there exists in the out-patient department of a children's hospital a great wealth of material, interesting and important from the student's point of view. Therefore it is in the out-patient department (where the work is akin to what his own will be later on) that he should and can obtain most of his training in paediatrics. This system of ambulant treatment of the sick child is not only possible, but it is in many instances advisable, since in this way there is retained for him an individual nurse who will devote night and day to his care. If surgical treatment is decided upon it is becoming more and more the custom at the Royal Hospital for Sick Children, Glasgow, to keep the child in hospital only for a short time, and to permit him to go home to be under the care of his mother within two or three days after the operation.

Thus the remedy for the present unsatisfactory state of matters does not mean the erection of large children's hospitals. Indoor accommodation is only necessary for the treatment of infectious disease, for the special study of disease requiring strict supervision and elaborate apparatus, and for the care of children whose home conditions are impossible. I would recommend that out-patient departments for infants and children be instituted at all general hospitals with teaching schools, so that the medical student may have ample opportunities of getting an insight into this wealth of material. Let the student see most of his adult material in the wards and the bulk of his young patients in the out-patient department, and let most of his dispensary practice be among children. With an efficient staff of enthusiastic teachers the student would benefit to a tremendous extent. To my mind it is only in this way that the medical man of to-morrow will be thoroughly equipped and able to take a share in the maternity and child welfare schemes which are essential for guaranteeing us against the invalidism of the adult. If for economic reasons municipal aid in the treatment of the child is advisable, then the ideal staff of these State or municipal clinics would be recruited from the family doctors in the neighbourhood. By such a system the patient and the doctor would mutually benefit.

Duration of Medical Curriculum.

So far I have dealt chiefly with my subject as it affects the teaching of the student and the equipping of a sound family doctor. This is and always will be of prime importance, as most of us went to college to become, and in fact do become, family doctors. It will be a sad day for the man in the street, in spite of all the criticism levelled against the medical profession, if the supply of this valuable servant of society ever fails. One often hears it said that there is disappearing from our midst the good old type of family doctor—the all-round physician who is also able to undertake operations and who is an expert in obstetrics. There is, of course, no doubt that within recent years there have been great developments in medicine, and that many new fields—for example, throat and nose, gynaecology, and radiology—have been opened up, and that it is impossible for any one man to be expert in all these branches of medicine. Nevertheless, I do hold that it is possible for the graduate in medicine to be more versatile than he is. This, I am afraid, must mean more time given to his education. Medicine is no finite subject, but is always advancing, and what new vista will be opened up to-morrow no one can say. The possibilities in the discovery of the cause and prevention of disease are unlimited. This may be, and often is, in what appears to us the most unlikely direction, but it behoves those who practice medicine to be as catholic in their interests as possible. Instead of curtailing, as some reformers suggest, the number of sciences which we have been wont to learn, or at least gain an introduction to, the number of subjects and period of our study should be increased. Instead of five years, the medical course should, as it already does in Sweden, extend to seven or eight years. Why the term of apprenticeship should be seven years for him who makes a chair and only five for him who should have an understanding of the whole of science and biology and who is entrusted with matters of life and death is quite incomprehensible.

Academic Paediatrics.

I had not intended to dilate at such length on the duration of the medical course, but had rather wished to limit my closing remarks to a discussion of the academic side of paediatrics. It is the function of the academic centre to stimulate interest in the subject, to carry out research in the unknown fields, and to train teachers, and no medical school can be considered complete without such a department. This department need not, and in fact cannot, at least in any of our university towns, do all the routine

work of treating the sick children or the teaching of the students, and so cannot replace the outdoor departments I have previously referred to. It must be a department complete in itself with pathological and biochemical laboratories, or closely allied to the chief pathological and biochemical departments of the university, so that facilities for all branches of investigation are available. The latter arrangement is in many respects advisable, as it brings the pathological and biochemical investigations under the guidance of the expert and unites the clinical and scientific sides of the school, a union which cannot be too highly commended, as each has much to teach and learn from the other.

It must also be understood that this paediatric department be not limited to any one branch of the subject, but that the whole domain of medicine in childhood be represented. It is the neglect of this which, in my opinion, is undermining the influence of paediatrics. To open a ward in a general hospital for infants and feeding cases and call it a children's department is futile. The only real paediatric department must admit all patients under, say, 13 or 14 years of age, and should have special facilities for the care of the common infectious diseases. It is only in this way that a paediatrician with a wide and philosophical outlook can be trained, and the exponents of children's diseases be given the influence which the importance of their subject demands.

In addition to the ward or wards there must be an out-patient department, not only for the purpose of obtaining a wider clinical experience, but also for the observance of series of cases over a long number of years. Infantile paralysis and the rheumatic infection are good examples of diseases requiring prolonged care, so that an infantile paralysis clinic and a rheumatic or cardiac clinic are essential. Not only, however, is the observance of cases over a prolonged period necessary for the health of the patients, but also for enabling the physician to gain personal acquaintance with the life-history of disease. This is one of the most wanted desiderata of hospital experience, since as a rule so much time is taken up with the examination of new cases and the acutely ill that the patient is entirely lost sight of after his dismissal from the wards. In this connexion the fate of nephritis, of chronic pneumonia, of coeliac disease, and of cerebral tumour are examples which occur to the mind at once.

Nutrition and development are such important aspects of child life that facilities for their study must be provided. This means a liaison between the paediatric department and the welfare centres and school inspection centres in the city. And just as important for a complete understanding of child life is the question of mental development, which is only now beginning to receive attention. The mind, however, cannot be dissociated from the body, and hence one of the chief workers in this field must be the physician.

Such multifarious fields of study demand a large staff properly co-ordinated, but team work in medicine is now, and wisely so, the order of the day. Organized research will not necessarily produce a Pasteur or a John Hunter; genius fortunately will arise and flourish in spite of—in fact, it would almost at times seem to do so in virtue of—adversity, but by organized research the ordinary individual is kept most active and rendered most productive.

THE HIGH ALTITUDE TREATMENT OF PULMONARY TUBERCULOSIS.*

BY

O. AMREIN, M.D.,

MEDICAL SUPERINTENDENT OF THE ALTEIN SANATORIUM, AROSA.

I AM far from declaring high altitude climate to be a panacea for pulmonary tuberculosis, but an extensive personal experience of over 20,000 patients, not only in Arosa, but also in the course of my travels over the world and in all climates, has strongly confirmed my conviction of the superiority of the Swiss climate to all others. I myself have experienced the benefits. I first went up to Arosa thirty-six years ago suffering from pulmonary tuberculosis, both lungs badly affected, a so-called "hopeless case," against the advice of our family doctor, who thought I was going to lay my bones among snow and ice. I have become fit and well, have been able to prosecute my work in the lowlands, and, without any relapse, have been lucky enough to work hard for nearly thirty years. The high altitude climate is not the only "stimulant," but it certainly has a great tonic effect, and possesses many advantages derived from such beneficial elements as the pure, cold, and extremely dry air, the abundance of sunshine, and the richness in light and ultra-violet rays even on cloudy days. Therefore open-air treatment can be carried out in almost any weather and under the best meteorological conditions.

Especially benefited by treatment at high altitudes are children who are delicate and may have incipient tuberculosis. Children suffering from swollen hilar glands and generally of the glandular type also do very well at high altitudes. They must be kept quiet until they become apyrexial, but afterwards they may be permitted to move about and enjoy exercise in the open air, combined with sun treatment, which can be carried out nowhere better than at high altitudes. To one of the two children's clinics directed by myself, where no infectious cases are taken and where they are staying under medical supervision, an open-air school is attached.

Adults suffering from pulmonary tuberculosis form the majority of our patients at high altitudes, and, of course, here as elsewhere the early cases do best—those with only slight signs at the apices, slight dullness on percussion, altered breathing, rough inspiratory sounds, prolonged and increased expiration, broncho-vesicular or bronchial breathing with small crepitations, and perhaps a small rise of temperature, following, in some cases, an alarming early haemorrhage. Yet sometimes, although we can detect scarcely any physical changes at the apices, a good prognosis cannot be given, since a continuous process is spreading downwards from the apices into the lungs.

Special care is required in our climate, and we must keep at rest on their arrival even apyrexial patients with initial lesions, in order to let them become well acclimatized. Early infraclavicular infiltration especially requires rest treatment for a considerable time. In this form there is slight dullness below the clavicle and bronchial or broncho-vesicular breathing with fine crepitations or rales, without any very appreciable change at the apex. Sometimes these signs occur in the axilla; the whole affection is acute, and tends to excavation. But such cases do very well at high altitudes, and may sometimes heal without the formation of a cavity or even after a small cavity has been formed. I myself and one of my assistants have published details of good results in such cases, and they are confirmed by various other authors; there is no justification for the statement that high altitude treatment is unsuitable. The necessarily prolonged rest treatment can nowhere be better carried out than in our mountain climate, where patients can lie out on the balconies in their beds, and later on in their chairs, in any weather; moreover, they do not become slack and flabby as in the lowlands or at the middle altitudes. They must, of course, be under strict, careful, and skilful medical supervision at a good sanatorium.

Sometimes, two or three weeks after the arrival of a patient who showed few physical signs at his apices or elsewhere, these become rather more distinct, with better audible crepitations, etc., even though the temperature and the general condition remain quite satisfactory. I term this an "initial reaction," and attribute it to the new and different climatic conditions. This reaction may develop during complete rest, and in some ways is comparable to a slight tuberculin reaction. The completely altered metabolism of the body may be responsible for it, and, to a certain degree, the deepening of the respiration in the thinner air. This occurrence emphasizes the

* A paper read before the Bournemouth Division of the British Medical Association on October 4th, 1929.

necessity of being especially careful, even with the light and so-called "initial cases," during the time of acclimatization—that is, during the first ten to fourteen days.

In early cases treated at our altitudes the lowered weight begins to increase in consequence of the improving appetite, while the cough and expectoration diminish and gradually disappear; the breathing becomes deeper and slower. The patient can then increase his exercise and take up some light sport, such as skating, careful climbing, or tobagganing. After three to six months—even slight cases require this length of time to heal permanently and to consolidate properly—the patient has apparently totally recovered; he has regained his working capacity, and the physical signs of disease have more or less disappeared. A skiagram shows a clearing up of the diffuse shadows over the apices and underneath the collar-bone, and the early infiltration underneath the collar-bone becomes more and more indistinct. Small circumscribed focal shadows appear, the signs of calcification, etc. Sometimes, however, there is a big discrepancy between the wonderful feeling of returning health and a local condition which does not change; in this respect initial and light cases require the same care and watching as more advanced ones.

With the spread of the process over the lungs, mostly downwards over the upper lobes and into the lower lobes, the destruction of lung tissue and the formation of cavities renders prognosis more doubtful; but it is astonishing how even such cases can be benefited by our high altitude treatment, and we often watch a case change from the exudative to the more hopeful fibrous type. When artificial pneumothorax and thoracoplasty were as yet unknown, many of my patients with large cavities in both lungs (and I had such myself) gained a permanent cure from climatic treatment alone. X-ray photographs show shrunk cavities, and even well-defined cavities may disappear.

The existence of pyrexia alone does not contraindicate high altitude treatment, but good results with fever cases depend largely upon whether there has been high temperature of long duration, and whether or not it has been accompanied by a rapid pulse. The pulse rate and the degree of fever enable us to judge the virulence of the infection, the character of the process, and whether these patients are fit for treatment at high altitudes or not. Patients with persistent fever above 101.5° F. and a pulse rate of 120 or more should not, as a rule, be sent to high altitudes. Exceptions occur, however. I remember some patients who came out with obstinate hectic fever over 102.5° F., and with a pulse rate of 120 to 130. After some months of complete rest in bed they showed first a diminution in the pulse rate, which was followed by gradual decrease of the temperature, and they eventually became apyrexial in nine to fourteen months. My personal experience indicates that patients who are sent to high altitudes with a temperature above 101.5° F. must not be kept there if, after some weeks of complete rest in bed, the pulse (having been 120 or higher) does not distinctly improve. But if the pulse has a good quality, and not too high a rate, patients with high fever do well; they often, indeed, lose an obstinate fever which did not yield at lower altitudes.

The type of fever, too—whether inverse, cyclic, or hectic—is of great importance. Cyclic fever comes on in attacks at intervals of three, four, or five weeks, and sometimes, in the case of female patients, in relation to the monthly period. Other bouts of fever caused by the absorption of toxins appear suddenly and irregularly from time to time. Such attacks make the prognosis doubtful.

Another interesting fact (to which I first drew attention many years ago) is the unexpected rise of the temperature at high altitudes in patients who had been suffering previously from syphilis. In all cases where obstinate fever persists in spite of complete rest, or where it even becomes higher, I now have a Wassermann blood test performed, and surprises in this respect are not uncommon. A similar phenomenon may occur in the case of old malarial patients who have been free from fever attacks in the lowlands, but have, as I have frequently seen, unexpected attacks of fever up in the mountains.

Cough and expectoration, as a rule, diminish in the cold and pure air, which also puts an end to the fatiguing night-sweats; but, sometimes, the sensitive membranes in the nose and throat become irritated and inflamed. When this is the case, it will be necessary to moisten the air of the room, and sometimes such patients must be sent down to a lower altitude.

The lessening of the fever, and the tonic effect of the thin air, have a beneficial effect on the appetite. We are able to keep our patients, even bedridden ones, out in the open air all day long, and our modern sanatoriums are so designed that the patient can be moved out in his bed on to the large and sheltered veraudah and private balconies in all states of the weather.

Special Indications and Contraindications for Treatment at High Altitudes.

Convalescents after pneumonia and pleurisy do very well in high altitudes in consequence of an improved respiratory function as a whole, aided by a more vigorous action of the auxiliary respiratory muscles.

Small residual effusions after empyema are often absorbed, the lung expanding again. On the other hand, obstinate dry pleural irritation, with rubbing and pain, may become worse in consequence of the deepening of breathing, and make it necessary to send such patients lower down.

Bronchitis generally is influenced for good, especially if associated with tuberculosis, but the rooms of these patients must be kept warm, and special care must be given.

Until a few years ago tuberculous laryngitis was considered to be a strict contraindication to treatment at high altitudes. But the fate of a patient suffering from tuberculosis of the throat depends a great deal on the pulmonary condition, and since at our sanatoriums we have a regular control of such patients by throat specialists, we can, and do, see surprising improvement in this regard too. Circumscribed ulcers are cauterized, and other special and local treatments are given. The treatment—in which perfect silence is insisted on, the patient not being allowed to speak for some months—is most efficacious; but patients with advanced tuberculosis of the larynx who have tissue destruction and large ulcerations do not do well at high altitudes owing to the dry air.

Asthmatic patients benefit if there is sufficient elasticity of the lung tissue, and good heart action.

As a rule, patients suffering from abdominal tuberculosis are not suitable for treatment at high altitudes, but there are exceptions, and systematic heliotherapy may be helpful. The results in cases of urogenital tuberculosis are doubtful.

Otitis media generally does well, the dry air clearly favouring the drying up of the tuberculous process.

In earlier days all persons with weakness or affection of the heart were warned not to go to high altitudes, but clinical observation and experience have proved this to be wrong. Those with compensated heart lesions may go without any risk, and patients with weakness of the heart muscle do well, and are even improved if they start with a long period of rest, exercise being subsequently introduced and slowly increased. But a weak and damaged heart will only withstand the high altitudes if no degenerative process is present, and if the heart has not to call on its reserves. Therefore, patients with uncompensated heart failure and myocarditis must not be sent to alpine stations, at any rate not for a long time.

Anaemia is generally improved, and often cured, but pernicious anaemia and leukaemia can only be benefited temporarily. I have seen splendid results in the case of patients coming from the tropics with grave anaemia, the result of previous malaria. The treatment with fresh liver or liver extracts, which is very useful in many forms of anaemia, is also effective in tuberculous patients.

Special Forms of Treatment.

Since 1902 I have been giving tuberculin to some patients, and I am still convinced that it can be of the greatest help. For many years now I have used only the absolutely harmless subepidermal (or intradermal) method of Sahli. The skin is the place of highly important immunizing reactions, and the local reaction in it indicates distinctly the necessary dosage, without doing harm, and without provoking harmful focal reactions in the lungs. Some authors have asserted that only those patients may be said

to be healed who no longer show any reaction to the very highest dose of tuberculin; but patients have been, and are, healed without tuberculin, and the really important thing is so to improve them that they will be able to undertake full work again after they have lost their expectoration and bacilli, and when crepitations or other signs of activity can no longer be found. Whether, for the time being or later, after years of successful work in normal life, they show a reaction to high doses of tuberculin or not, is, in my opinion, quite irrelevant.

I have tried the gold treatment, but only very rarely, although I have used it a little more often during the past year or two. The results are variable, and I have often seen hideous pigmentation and spotty discoloration of the skin, or skin irritability and bad eczema in patients treated elsewhere with sanocrysin. We are able to avoid such sequels by not giving too high or too frequent doses. But since, on the other hand, too small doses are relatively useless, the individual tolerance has to be determined with great care. I am using sanocrysin, as a rule, at intervals of five, eight, or ten days, starting with 0.05 gram and going no higher than a total dose of 4.5 to 5 grams of solganal. I have seen some astonishing results, especially in the shape of rapid disappearance of tubercle bacilli from the sputum, and the loss of fever.

I am very satisfied with the results of pneumothorax treatment at high altitudes. The practically sound lung runs much less risk there than it does in the lowlands. I have had good results, even in cases with bilateral affections, by treating the worse lung with an artificial pneumothorax. I have seen patients who had been given up lose their fever and obtain lasting benefit as the result of the combination of complete rest and careful pneumothorax treatment at Arosa. Good results also are by no means uncommon with patients treated by a large thoracoplasty, and I have had many who, after this most strenuous operation, have picked up again very soon at our altitudes.

A phrenicotomy is often very helpful in cases where thick adhesions prevent the administration of an artificial pneumothorax, or where a consequent more or less extensive collapse would endanger the other side. Phrenicotomy is also valuable as a preparatory operation for a later thoracoplasty, and enables one to watch the other lung, which has to take over more work from the badly affected one if collapsed or reduced in function. In all cases where this other lung has to be taken into special consideration treatment at high altitudes enables us to give special surgical treatment to the badly affected lung sooner than in climates where there is a risk to the other one from impure air or smoke. Sometimes the operation of Jacobaeus—namely, the burning through (intrathoracically) of fine adhesions—promotes collapse in cases of insufficient pneumothorax.

When treating patients by artificial pneumothorax it must be remembered that the barometric pressure exerts an influence on the pressure of the pneumothorax. Patients who have had injections of air or nitrogen at high altitudes absorb the gas much more quickly when they go down to the lowlands, and more frequent refills are necessary there. It is advisable to give a last injection shortly before the patients go down, and they soon have to be refilled there again. On the other hand, patients who are about to come up from the lowlands to high altitudes must not be injected shortly before their journey, or the last refill must be a very small one. The intrathoracic pressure must be kept *minus* before they travel up to the heights. This is not generally known, and I have seen quite a number of patients arrive after a large refill a few days before starting; they were short of breath, and showed circulatory derangements, dislocation of the mediastinum, etc.

As regards the dietetic treatment of tuberculosis we have long known that feeding is an essential and very important part of the treatment of tuberculous patients; Hippocrates emphasizes this point. Tuberculous patients, if very ill, have a tendency to lose weight, and the word "consumption" speaks for itself. As a matter of fact, a gain in weight by emaciated patients is always a very good and welcome sign, but stuffing patients with the sole object of making them fat is not effecting a cure, and much harm was done in this respect some twenty or thirty years ago, when tuberculous patients were urged to eat much meat and drink stout, etc.; as a reaction the vegetarian system was recommended, but this alone will not solve our problems, especially in high altitudes where everybody, and certainly the patients, needs more calories. More fresh fruit and raw vegetables in addition to cooked ones are given now, but they are combined with a rational meat diet. Special food preparations containing vitamins are proving valuable.

During the past months a new method of diet has received prominence in Germany; in this "saltless diet," which was inaugurated by Gerson, and improved by Hermannsdörffer at Professor Sauerbruch's clinic, a preparation containing other minerals is given instead of common salt with cod-liver oil twice a day. It requires skilled preparation in the kitchen to make this food palatable, and it calls for great perseverance on the part of the patients. There is no doubt that this diet may produce surprisingly beneficial results in cases of surgical tuberculosis, and I have seen marvellous results in cases of lupus and of tuberculous affections of the bones and joints. Although we tried this saltless diet in a great number of lung cases at the Altein sanatorium at Arosa, we could not obtain any more definite benefit than with our ordinary treatment. We do "individualize," however, the food of our patients where necessary, and all forms of diet are given; but, in common with other lung specialists, I have come to the conclusion that this modern saltless treatment, so far as lung patients are concerned, does not justify the enthusiastic statements which have been made.

In estimating the value of various treatments the blood sedimentation test is most helpful. Figures higher than 5-6 minutes in the average indicate that an active process is present, and a fall of the figures from 60–50 or even 30–20 to 8–6–5 enables us to give a hopeful prognosis. However, the clinical improvement may sometimes occur first and the amelioration of the sedimentation reaction follow later on.

Statistical Evidence.

Thirty years of personal work with lung patients have only served to strengthen more and more my conviction of the superiority of the treatment at high altitudes. The large statistical tables prepared by the late Theodore Williams, and shown at the International Tuberculosis Congress in London in 1902, demonstrated that the best results were obtained at high altitudes. The statistics of the so-called "immediate results" after a course of treatment at Arosa, worked out from 4,000 cases, the material being provided by four different physicians practising as specialists at Arosa, show that in Stage I cases there were 93 per cent. of positive cures; in Stage II cases 74 per cent.; and in Stage III cases 41 per cent.

Statistics of the more permanent results, seven, ten, or more years after stopping treatment, were drawn up by Turban at Davos, Ruge at Arosa, and Bernstein-Kohan, whose investigation was conducted under my supervision from a mass of material accumulated in my own private practice before the time of the Altein Sanatorium; these show that permanent results were obtained in 86.5 per cent. of Stage I cases; in 12 per cent. of Stage II cases; and in 7.5 per cent. of Stage III cases. At the beginning of their treatment at Arosa 83.6 per cent. of patients with a durable result were apyrexial, and 82 per cent. had a pulse rate below 100. In 40.86 per cent. of all patients there were still some physical signs but no evidence of activity one to nine years after their treatment. The sputum still contained bacilli in 3.8 per cent.; 18 per cent. had some active trouble, and continued under treatment. The best results were obtained with patients between the ages of 20 and 30 years (51.9 per cent. of durable results), and with patients who started treatment within six months after the first symptoms were observed. Taking all stages together, 63 per cent. of all the patients were still fully fit for work one to nine years after stopping treatment.

General Notes.

Treatment at high altitudes can be started or continued at any time of the year with absolutely the same effect. Patients who are doing well at high altitude places during the winter sometimes think that they should spend the

summer at home or at a lower altitude; by so doing they generally become worse, and, returning to us in winter, nearly always show a relapse. Nearly all the good and lasting "cures" have been obtained by continuing the treatment until a sufficiently safe state of consolidation has been reached. There is no need to fear the effect of the snow-melting period at the high altitude health resorts in spring; either the weather is beautifully warm and sunny or snow falls; but even this last is preferable to the treacherous windy and damp weather with April showers which is usual at low altitudes at this time. Early spring weather is an especially risky time for lung patients in the lowlands, and induces every year many severe colds. Another difficulty is that some doctors order their patients home at that time, and are astonished that they then grow worse. Those patients would have continued to improve had they been allowed to remain out during the spring and summer. I cannot over-emphasize the importance of continuous treatment, which is far preferable to the "wintering" only.

The patient's co-operation is essential, and he must have full confidence in his medical adviser. Doctors who send patients abroad can do great harm by being too optimistic at first. To encourage the patient so many say: "Oh, a few months out there will put you all right." The few months pass, the patient feels better, and gets discontented at not being allowed to go home. If they were warned at first: "You will probably get well, but it may take a long time; we cannot know it yet, and you must play the game," people would be spared a false idea and much disappointment. Doctors should also warn relations not to urge patients to come home; several patients under my care were completely upset by injudicious home letters. In 99 cases out of 100 it is quite impossible to "cure" at home faithfully. After many years of attending lung patients I must express my conviction that patients will nearly always do much better in a good sanatorium than at open hotels.

TOXIC GOITRE.*

BY

PETER McEWAN, M.A., M.B., F.R.C.S.ED.,

HONORARY SURGEON, BRADFORD ROYAL INFIRMARY, AND HARTLEY HOSPITAL, COLNE.

THE term "toxic goitre" is used in this paper to include all forms of thyrotoxicosis: primary Graves's disease—that is, where no enlargement of the thyroid gland existed before the onset of the disease—and secondary Graves's disease, where toxic symptoms arise in a patient with a pre-existing goitre. "Toxic adenoma" is used to signify thyrotoxicosis where one or more discrete adenomata are present in the gland.

CLASSIFICATION.

Toxic goitre gives rise to a wide variety of clinical pictures. The symptoms of the disease are numerous, and are combined in varying numbers and severity, so that each case is essentially a study in itself. There is, however, a dividing line between the primary and the secondary types; you may see this clearly illustrated by looking at the cut surfaces of glands removed at operation—the primary shows a uniform surface, the secondary a surface marked by various types of degeneration. Clinically, the primary is characterized by exacerbations or crises, with periods of improvement, and may result, with adequate time and care, in a complete cure; or it may pass into a subacute or chronic state, which is difficult to distinguish from the secondary. The secondary type, including the adenomatous variety, is characterized by steady progress, free from ups and downs. The emphasis in the primary form is on the nervous symptoms, whereas the secondary causes a progressive deterioration of the cardio-vascular system. The two types, however, are so interlinked that in many individual cases it is difficult to place the case definitely in either group.

SYMPTOMATOLOGY AND IDENTIFICATION.

The classical group of symptoms of Graves's disease used to be given as goitre, tachycardia, fine fibrillary tremor of the fingers, and exophthalmos, and where these are present the disease is easily recognized. The chief additional symptoms are easily produced fatigue, palpitation, loss of weight, excessive perspiration, nervousness, digestive derangements, and, in advanced cases, auricular fibrillation and even dropsy.

The patient in many cases never dreams of connecting her symptoms with an enlarged thyroid; she will even say that her present complaints have nothing to do with her goitre, as she has had that for years and it has given her no trouble. Neither is it easy for the doctor in many cases to recognize and convince himself of the causal connexion. Such cases fall chiefly into three groups.

The first group includes patients who complain of some falling off in general health, and on inquiry are found to have some palpitation, nervousness, excessive perspiration, loss of weight, and are easily fatigued. That a goitre is often the cause of such falling off in health can be clearly demonstrated by three facts: first, the marked improvement in general health which often occurs after a goitre, considered non-toxic, is removed for mechanical reasons; secondly, the severe toxic reaction which can occur during the first forty-eight hours after operation in a patient with only slight toxic symptoms; and thirdly, the dramatic improvement in this group of cases after operation. The immediate improvement is nearly always obvious on the third to fifth day after operation, and consists in a feeling of restfulness and general well-being, with cessation of uncomfortable pulsations and throbbing in precordia or neck; the ultimate improvement is a return to normal weight, strength, and general health.

The second group consists of patients with cardio-vascular degeneration who for years have had an apparently harmless goitre. The causal relationship of such a goitre to the premature degenerative changes has in the past been often unrecognized; but if such a goitre (which has become toxic) is operated on, a marked change in the outlook will soon follow, unless the organic degenerative changes have been allowed to become hopelessly advanced.

The third group comprises patients with an anomalous or atypical mixture of symptoms. For example, a man, aged 61, sent in as a case of diabetes, complained of excessive fatigue on very slight exertion. He had almost no exophthalmos, a very coarse tremor of the hands, pulse 96, and a slight symmetrical soft enlargement of the thyroid, without any thrill. After hemithyroidectomy he felt better in three days; nine months later, having increased 3 st. in weight, he resumed his work. A female teacher, aged 55, had fallen off in weight and lost her physical and mental energy, concurrently with a slight increase in size of her parenchymatous goitre; four months after a bilateral resection she had put on a stone in weight, resumed work, and regained, as she said, her *joie de vivre*.

It is essential, of course, in all such cases to form a careful clinical picture. A female patient who was sent to me recently because of loss of strength and weakness of the legs, with an obvious goitre, was suffering from locomotor ataxia. Such diseases as phthisis, diabetes, and carcinoma must be excluded. If this care be taken, operations on a coexisting goitre will in the above groups of cases rarely fail to produce a good, often a spectacular, result. Where cardio-vascular degeneration is the symptom early recognition is of vital importance, since if operation is carried out reasonably early it entirely alters the outlook, and if delayed too long the case becomes an excessively bad risk.

TREATMENT.

We are comparatively ignorant of the causal factors of toxic goitre and of the mechanism by which these causal factors stimulate and derange the thyroid gland, as well as of the natural history of the disease. It is not easy to give a prognosis in an individual case. It follows that definite lines of treatment are not easy to lay down. American surgeons give a brief and clear answer to this question of treatment—namely, toxic goitre has become a surgical disease; operation cures quickly and safely; conservative

* Abstract of an address delivered to the Scarborough Division of the British Medical Association.

treatment is slow and uncertain, and apt to inflict permanent damage to the heart.

The leaders of surgical opinion in this country take a different view. Dunhill considers that primary Graves's disease should be given a six months' trial of non-operative treatment, and not till then—and then only if such treatment does not seem to present a prospect of cure—should operation be considered. The length of time may be more than the patient can or will afford, and economic reasons may force a decision between incomplete cure and chronic ill health on the one hand, and operation on the other. The wisdom of the conservative treatment of primary cases is shown by the fact that many of these patients return in course of time to apparently perfect and normal health, in possession of a useful thyroid gland. Such a result is no doubt preferable to any that operation can produce, and where the patient is prepared to afford a length of time necessary to endure it she should be given the chance.

In the uncured residue of those primary cases, and to a large extent in secondary Graves's disease, operation is the method of choice. While this opinion is necessarily based on the clinical results, examination of the glands removed shows that it rests on a sound pathological basis. The glands show in varying measure areas of degeneration (colloid, cystic, fibrous, nodular, calcareous), contrasting with the uniform hypertrophy of primary Graves's disease. They are end-results of disease, and their retention within the body is detrimental to health. It is not unlikely that the character of the toxicity alters—that the primary type is really a pure hyperthyroidism which provides an intense but temporary stimulus to the nervous system, whereas the secondary is a dysthyroidism, pouring into the blood a perverted secretion which causes a slow but progressive deterioration in the cardio-vascular system. If this view is correct, operation is definitely indicated in advanced primary and in secondary Graves's disease.

In toxic adenoma operation is essential. The removal of the adenoma relieves the symptoms quickly and with certainty, and, while not repairing organic damage, radically changes the outlook. The rate of progress of toxic adenoma may be illustrated by the following cases.

A. B., female, single, aged 37; complained of intermittent aphonia, "croaky voice," ill health, chronic goitre. The goitre was first noticed when she was 17, when she had typical symptoms of secondary toxic goitre (trembling, nervousness, weakness, sweating, pulse 130–140, no exophthalmos). She was off work for twenty-six weeks. Treated by x rays for two and a half years, supervised another year. Relapse at 21; off work nineteen weeks. She had pneumonia at 27, and had been off work for twenty weeks each year since then. Symptoms had persisted during twenty years; tremulousness, weakness, excessive sweating, palpitation, pulse 106; no exophthalmos. There was complete paralysis of the left vocal cord, and a compressed and displaced trachea, due to a large adenoma the size of a goose's egg, partly substernal, left-sided. This was removed at operation, and after a severe reaction during the first forty-eight hours the patient made a good recovery.

C. D., aged 49. Advanced cardiac disease. Pulse 170 and very irregular. Had a large goitre with multiple adenomata. Was in good health till 41, since when health has deteriorated, with concurrent development and growth of goitre. This patient, after careful medical treatment, failed to improve, and was dismissed as hopeless and inoperable.

E. F., aged 65. Was perfectly healthy and never knew fatigue till two and a half years ago, when for the first time she noticed a commencing goitre, which has steadily grown, and now has several adenomata in the left lobe, and one in the right lobe. She has become weak, thin, breathless, incapable of exertion, depressed. Her pulse was rapid and irregular, and after careful supervision the consulting physician thought the risk of operation too great. The right lobe and part of the left lobe were removed. In the following three months she gained a stone in weight, and though her heart still fibrillates, she is a different woman.

It may be noted that in these three cases the duration before serious complication ensued was, in the patient of 37, twenty years; in the patient of 49 eight years; and in the patient of 65 two to three years—that is, in a definite relation to the activity of the gland.

G. H., female, aged 47, had a large median adenoma and a small adenoma of the left lobe, and wished them removed for mechanical reasons. My house-surgeon records "no toxic symptoms." A lump was first noticed twelve years ago; it was then the size of a marble. It had grown quickly during the last two years. Her only general symptoms were easy fatigue and very slight tremor. After operation her improvement in weight, strength, and general health was rapid and permanent. She brought with her a man who had increased in weight from 6 st. 2 lb. to 9 st. 7 lb. after a similar operation. Both have scars practically invisible.

Brilliant results such as the above are common in the surgery of the toxic thyroid, and cases could easily be multiplied did space permit. The gratitude of such patients is not easily measured. Many of them enter on a new life, and this is true, not merely of toxic adenoma, but of all forms of toxic goitre.

RISK OF TOXICITY OCCURRING IN A NON-TOXIC GOITRE.

The question arises, What risk is there of the chronically enlarged thyroid becoming toxic? Jackson states that by the time a patient with a non-toxic adenoma reaches 45 the chances are one to two that toxic symptoms will develop; that the adenoma is present for eighteen to twenty-five years before toxic symptoms arise; that their onset is subtle and gradual, and inflicts serious and lasting injury within four years, at an average age of 44 years. He uses "toxic adenoma" in the larger sense of "adenomatous goitre." Dr. Quervain states that after a bilateral resection for parenchymatous goitre (non-toxic) recurrence is comparatively frequent among the young, however thoroughly the operation may have been performed, but in older patients the power to prevent recurrences seems to have become exhausted. This would tend to show that there is a diminution of thyroid activity—a sort of thyroid menopause—round about 40 years of age. With diminished activity degenerations are prone to occur and toxicity to arise. I have observed in a number of cases that toxic symptoms date from about 40 years of age, and believe that from this age onwards they should be kept under supervision with a view to early detection of toxic phenomena.

CONSERVATIVE TREATMENT.

The sheet anchor is time and rest, the length of time varying from six months to three years. Septic foci should, when practicable, be removed. There are many cases which have cleared up or materially improved after this has been done. It is well, however, not to exaggerate the value of this procedure, and in severe cases it should be undertaken with due care, being not entirely free from risk. Even if one takes the view that toxic goitre is due to an infection which selects the thyroid because of the predisposition of the individual, following a disorder of the reactions of the ductless glands from sex trauma or overstrain, the removal of a septic focus whilst the patient is in a state of toxaemia may have a disappointing result.

The following case shows what can be accomplished by treatment of septic foci and their sequelae. It was under the sole care of a general practitioner, who has given me his notes.

History and Examination.—Mrs. W., aged 54. Three years ago this patient came under my care and was almost bedridden: nearly every joint in the body had been stiffened, and most were swollen and painful. There was extremely limited movement of the limbs, and the patient could hardly open her jaws sufficiently wide to take anything but liquid nourishment. The pulse rate was about 150; the pulse was very intermittent and irregular, and the cardiac sounds in keeping. There was a systolic apical murmur with mitral regurgitation. Weight (three years ago) 6 st. Left lobe of thyroid enlarged (about the size of a Tangerine orange)—probable toxic adenoma—and had been steadily enlarging for the past fifteen years. Teeth very foul, spongy, and caked almost to a solid mass. It was impossible to differentiate separately the lower incisors, and the remainder of her teeth were more or less a solid mass. The ankles were markedly oedematous. There were large "rheumatic" nodules at areas of pressure; one nodule, about the size of a hen's egg, over the third lumbar spine, and smaller ones over the first and second dorsal spines. On each elbow was a nodule about the size of a pigeon's egg, and several smaller ones down the ulnar aspect of the arm—pressure nodules. The patient could not reach her chin with either hand, and could not attempt to do her hair or wash her own face. She hobbled on sticks to a chair at her fireside; that was her sole effort at walking.

Previous Treatment.—As far as could be gathered this had consisted of thyroid tablets, thrice daily after meals, and aspirin at bedtime. She had been forbidden meat and milk.

Treatment (carried out by me).—Intermediate removal of all the teeth, under novocain. She was put on a diet of beef-tea and nourishing fluids, including milk; she could not take solids. Orally collosol sulphur and collosol iodine for alternate fortnights. Six weeks after removal of the teeth the patient received a course

of six injections of mixed streptococcal vaccine. After three months the pulse rate had come down to 100; the heart had become much more regular; the nodules had almost disappeared and the heart murmurs were hardly discernible. The adenoma of the thyroid had diminished by half. Joint movements had slightly improved, especially the jaw, which had markedly improved. During the subsequent three months the patient was kept on colloso1 sulphur and iodine and as full a diet as possible. At the end of this period she was provided with artificial dentures, and masticated food for the first time for years with comfort. At the end of a further three months I gave another course of six injections of streptococcal vaccine; collosols as before, with full diet, including meat, vegetables, and fruit—the latter in plenty.

One year after beginning treatment the patient was sent to Bath for a six weeks' course of exercises and massage. On her return she was able to come downstairs with the aid of one stick, to perform her ablutions, and to dress herself and to attend to her own hair.

Exercises were maintained at home for another six months. Further course of six injections of streptococcal vaccine, at the end of which time the pulse rate had come down to 84 and was perfectly regular. Heart sounds normal. All signs of adenoma had disappeared and the patient was able to do her own shopping out of doors. The nodules had entirely disappeared, and only slight oedema of ankles reappeared towards the end of the evening.

July, 1929: Patient remains very well. Sleeps well at night, takes hearty meals, and generally is a vastly improved subject. Weight has steadily risen to 8 st. 12 lb. Throughout treatment mag. sulph. in graduated doses was taken to keep bowels regulated.

The value of *x* rays is a thorny and unsettled question. The surgeon does not as a rule see a big enough series of cases so treated to offer a fair judgement; he sees the bad results, which certainly occur. *X* rays should not be used for toxic adenoma, probably not for secondary Graves's disease, and their sphere in primary Graves's disease is still a matter of dispute.

Among the numerous drugs recommended there is one of outstanding importance—namely, iodine. As an adjuvant to surgery, lugol (a solution of iodine 5 per cent. and potassium iodide 10 per cent. in water), introduced by Plummer in 1922, has proved its value. In the great majority of cases of toxic goitre it improves the patient (often in a striking degree) before operation, and is a safeguard against post-operative thyrotoxicosis. Whilst as a stand-by to the surgeon it is invaluable, the use of iodine as a continued medical treatment is open to question. Its beneficial effects are apt to be temporary; its excessive use may induce hyperthyroidism, and it loses most of its value to the surgeon should operation subsequently be required. I have seen four patients during the last year who had had careful iodine treatment for about three months; all of them had the characteristically firm gland which the continued use of iodine induces; two, aged 46 and 48 respectively, were inoperable on account of their cardiac condition; the other two, females, aged 26 and 48, had pulses of 160 and 140 respectively, and after being carefully piloted through the two-stage operation made a very satisfactory recovery. It would appear in these four cases that iodine in the amount given had no curative effect, and may even have been injurious. Cases of toxic goitre have been cured by potassium iodide, but possibly the old view of the danger of iodine as a medical treatment of toxic goitre is well founded. The history of one of these cases is as follows.

I. J., female, single, aged 28, a few weeks after an attack of erysipelas had a sudden and very violent onset of Graves's disease, with a running pulse of 180, severe gastro-intestinal disturbance, restlessness, and tremors of marked exophthalmos. She was treated with lugol (2 minims three times a day) for three months. I then saw her for the first time, with typical symptoms of primary Graves's disease, pulse 160, and a firm "iodine" gland showing a slight bilateral enlargement. She was admitted to hospital for a month's observation, and continued very ill, pulse 150–160. Lugol was then resumed for a month (7 minims thrice daily), and she immediately improved in every way, pulse 130. Right hemithyroidectomy was performed, with very marked improvement, the pulse falling as low as 100. After six weeks two very septic enlarged tonsils were removed. This caused a slight relapse. During the next four weeks the patient remained stationary (pulse 115–120), and about three-fourths of the left lobe was accordingly resected. Rapid improvement followed. About three weeks after the operation the patient said to me, "I have not felt so well for seven years." It appears that she had been in indifferent health for seven years, nervous and easily tired.

This period of nervous debility—in reality a mild thyrotoxicosis (what might be called the prodromal stage of toxic goitre)—lasting some few years, is a not infrequent prelude to an identified attack, and is the period when preventive medicine (or surgery, in adenomatous cases) is of especial value. It is difficult to identify a thyrotoxicosis—possibly the pulse pressure (a convenient and fairly accurate substitute for the basal metabolic rate) might help—and the type of patient is not easily persuaded to rest. I believe the following case is an example of prophylactic treatment.

K. L., female, married, of very active habits, was admitted to a nursing home for fractured patella. She was considered to be "on the borders of a nervous breakdown," was nervous, and had fallen off in weight and strength; pulse 110–120. A consulting physician was unable to say whether or not she was in the prodromal stage of toxic goitre. She was carefully warned and had a few months' complete rest. She regained good health, and is still, two or three years thereafter, strong and robust.

OBJECTIONS TO OPERATION.

Although the operative treatment of toxic goitre produces results as dramatic and as excellent as any other branch of surgery can show, certain objections to this particular operation are often present in the minds of the patient and especially of the doctor.

1. The hope of non-operative cure.

2. The dislike of the removal of such an important organ as the thyroid. The aim of surgery is to remove, not a useful, but a deleterious gland.

3. The risk of operation. At the present day this is certainly small. The death rate depends upon whether the surgeon chooses to accept the very bad risks, especially the late secondary cases with advanced cardiac degeneration and rapid, irregular, and feeble pulse; on careful pre-operative and post-operative care; on gentleness of handling; absence of loss of blood during operation; and drainage of the wound. Of about eighty cases I have operated on from 1921 to 1929, I have lost two only, both before the lugol period. One was a case of primary Graves's disease with extreme emaciation, rapid pulse, and anorexia; the other, a woman, aged 63, with a bilateral adenomatous goitre in which neither the physician nor myself had suspected a toxic element; she died of acute thyrotoxicosis. At the present day, I believe, both would have survived.

4. The scars on the neck. These are wonderfully good, often scarcely visible, and many patients are rather proud of them.

5. Injury to the voice. If one of the recurrent laryngeal nerves should be damaged some change in voice may follow; if both are injured, it is a serious sequel. The risk of injuring one of these nerves is now very small. It is never negligible. Jackson considers that since the patient may have a paralysed vocal cord without being aware of it, laryngoscopic examination should be a routine before operation. Improved technique has reduced this risk to a slight one. I have one patient only with a damaged voice, though cured of a severe primary Graves's disease.

6. Incomplete cure and possible relapse. Dunhill lays down the rule that no surgeon should operate on toxic goitre who is not prepared to remove enough of the thyroid gland to effect a cure, otherwise he will have sufficient bad results to render a serious disservice to surgery. If this rule be followed, relapse need not be feared. It might be asked, What constitutes a cure? Slight remnants of the disease may remain (notably some prominence of the eyes), but a cure may be regarded as a return to active life, with a satisfactory prospect of longevity.

Hemithyroidectomy is sometimes curative; as a rule it effects only a partial cure, and it is generally agreed that the removal of three-quarters to seven-eighths of the gland is necessary. The fact that Nature can carry on satisfactorily with a mere remnant of a gland so important as the thyroid is a tribute to her wonderful adaptability.

Had space permitted I should have liked to quote cases illustrative of clinical opinions expressed above. In conclusion, I wish to express the indebtedness that every surgeon who operates on toxic goitre must feel to the leaders of opinion on the subject.

FAVUS (ACHORION QUINCKEANUM) OF THE MALE GENITALIA.

BY

J. GOODWIN TOMKINSON, M.D.,

PHYSICIAN TO THE SKIN WARDS AND SKIN ELECTRICIAN, WESTERN INFIRMARY, GLASGOW; M'CALL ANDERSON MEMORIAL LECTURER IN DERMATOLOGY, GLASGOW UNIVERSITY.

IT is stated in some dermatological textbooks that favus is more often seen in Scotland than in England. If so its incidence south of the border is decidedly infrequent.

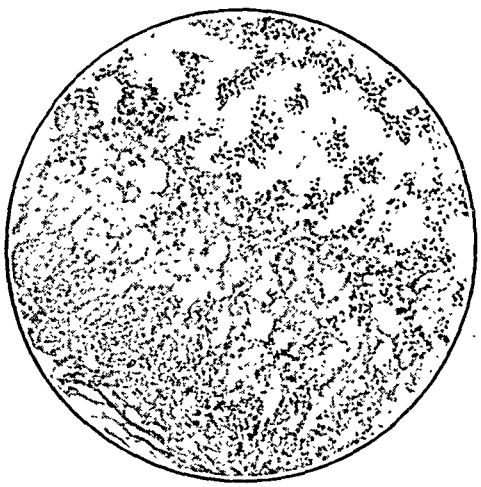

FIG. 1.—Photomicrograph of section of scutulum, showing spores and mycelium of *Achorion quinckeanum* in contact with epidermal cells.

I have never seen it in private practice, and in my hospital clinic and in the skin clinic of the Glasgow education authority, where large numbers of patients pass through my hands, it is of rare occurrence. In but few of these cases has the glabrous skin been affected. In that distribution if the typical sulphur-coloured scutula are present—there is nothing else like them—the diagnosis is strikingly obvious. Occasionally, however, some of the lesions simulate ringworm, but in the cases where there has been no involvement of the scalp which have come under my notice and been diagnosed as favus, I can recall none in which scutula were absent from all the lesions.

Variation from typical distribution of skin diseases may be a confusing factor in diagnosis, especially in those affections devoid of pronounced characteristic signs. In other diseases the signs may be so convincing that the unusual topographical feature presents no obstacle to the identification of the affection.

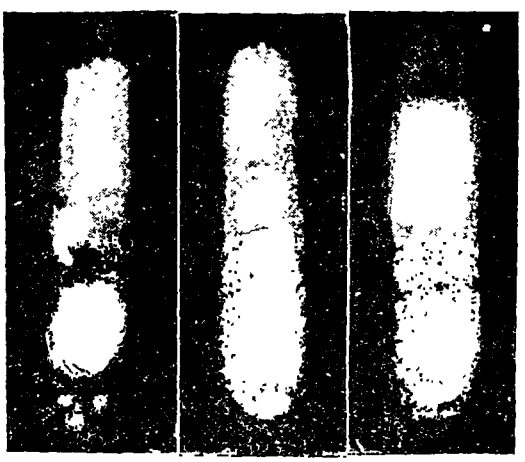

FIG. 2.—Cultures of *Achorion quinckeanum*—white, finely powdery, and showing at bottom of first and third tubes a tendency to acuminate shape.

Early in July of this year a patient presented himself at my hospital clinic complaining of an affection of the penis and scrotum. To my surprise—for there was no mistaking the disease—he was the subject of favus in those sites. The left half of the scrotum showed typical umbilicated yellow scutula, and the same region of the penis similar lesions, which, however, did not exhibit the same degree of umbilication. It was the first time that favus in the genital region had come to my notice, and it occurs with such extreme rarity in that situation that I feel no further justification is needed for reporting this case. There were other lesions present, but none of them showed typical scutula. Two, on the inner aspect of the left thigh, which were evidently extending and coalescing, presented an erythematous appearance, and one of these showed a ring-like development, suggestive of vesiculation, and some scaling. Another lesion was pustular, and one showed black dots, due, possibly, to some adventitious element masking the yellow colour of minute developing scutula.

The causative fungus in the preponderating number of cases of scalp favus in man is the *Achorion schönleinii*. Sabouraud has recorded 200 scalp cases due to it. There

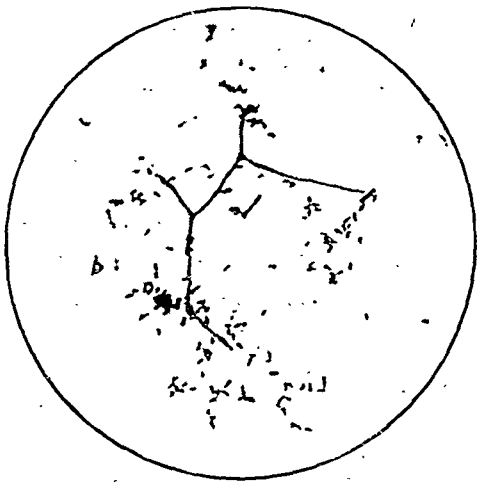

FIG. 3.—Photomicrograph of *Achorion quinckeanum* from culture of scutulum on Sabouraud's medium. Note dichotomous branching of mycelium. Spores of varying size and shape—mainly oval, with one end rather more rounded than the other.

are, however, other varieties of achorion met with, mainly in the lower animals. It has been advanced that those cases in the human subject in which the scalp is unaffected are due to one or other of these lower animal varieties. Be that as it may, there were no scalp lesions present in this particular case.

A scutulum was broken up and portions sown on Sabouraud's media, and Dr. Ernest Dunlop of the pathological department made a section of another of which an excellent photomicrograph was taken. The cultural attempts were successful and showed growths of *Achorion quinckeanum*, a variety found in the cat and mouse. The accompanying illustration shows the cultures, which are white and finely powdery in appearance, with a tendency in some to acquire an acuminate shape. The photomicrograph of the cultures shows a dichotomously branching mycelium and spores of varying size and shape, mainly oval, some with one end more rounded than the other.

Inquiry elicited that there were mice in the patient's home, but no cats. I was unsuccessful in getting any of the mice. How had the patient become infected? No other member of the family had it. It appears that he had bought some shirts shortly before he had noticed the lesions. He wore an undervest. The first lesions to appear were the genital ones. The custom of tucking in the anterior lower part of the shirt about the inguinal and genital regions and the drawing forward of the tail

of the garment brings this article of underwear into very intimate contact with those parts where heat and moisture are favourable to fungus growth. It is possible that the new shirt may have borne the contagion into the house; on the other hand, a favic mouse from the household group may have contaminated it. This is mere conjecture, for many possible ways of infection suggest themselves. Apropos of this, I once treated three bachelor brothers for tinea cruris. The first, whose epidermal scales microscopically examined showed the *Epidermophyton inguinale*, had used a strange closet—of the earth variety, I believe—when out shooting. Doubtless the other two had contracted the disease from one of the water-closets in their country house, common to them all.

The scutula were removed, and all the lesions cleared up within a fortnight under salicylic acid and ammoniated mercury ointments of appropriate strength. It was found necessary to employ a boric acid and calamine lotion occasionally, after washing off the ointment, owing to the sensitiveness of the skin of the parts.

THE RUNNING EAR.*

BY

H. NORMAN BARNETT, F.R.C.S.Ed.,

SURGEON, BATH EAR, NOSE AND THROAT HOSPITAL.

THE running ear is the term used by the mothers of England and the man in the street for designating the condition of suppurative otitis media, which has as its sign the outflow of pus from the external auditory meatus. There is no greater reproach to the science and practice of otology than that a number of persons of all ages are going about suffering from this serious complaint. There would appear to be no clear conception in the minds of many practitioners, of the public, and of some of the public authorities of the true significance and seriousness of the condition. For example, the Board of Education in its annual report for the year 1922 (p. 63) states that arrangements have been made for the treatment of "uncomplicated otorrhœa at *minor* ailments clinics" (the italics are mine), and states that the treatment is carried out by a school nurse at the school or the clinic. On certain representation being made to the Board, the reply was that "cases of discharging ears are as a general rule suitable for treatment by the school nurses at the school clinic under the direct supervision of the school medical officer, and the local authority should arrange for this course to be adopted." School medical officers are thus prevented from sending *all* their cases of suppurative otitis media to clinics held by otologists, and this procedure is in force at the present time. When such is the attitude of a responsible public body, is it any wonder that there is widespread misunderstanding of the condition in the minds of many medical practitioners and in those of the public?

Needless to say, every child or adult suffering from suppurative otitis media has a very serious complaint and should be under the care of an otologist. The disease, if carefully treated, is eminently curable. If it is not cured, every fresh nasopharyngeal affection may light up, not merely middle-ear disease, but mastoid infection, which may spread to the brain with dire results.

The prevention of the running ear should, therefore, first engage our attention, and with this object in view the tympanic membrane should, as a rule, be incised in all acute middle-ear conditions at an early date. It is regretted that the Association of School Medical Officers does not seem to have taken up the challenge that was thrown down by a correspondent in the *British Medical Journal* on April 20th, 1929, asking for an authoritative pronouncement on the question of paracentesis in such conditions. Otologists have declared themselves in favour of this procedure, but the Association of School Medical Officers has made no comment.

If suppurative otitis media occurs in spite of paracentesis, then it should be treated as a serious disorder, preferably by putting the patient to bed, or at any rate confining him to the house and thoroughly disinfecting the external auditory meatus and, as far as possible, the tympanum. Personally, I employ frequent cleansing with 10 volumes of hydrogen peroxide, followed by pipetting out with warm boric lotion, drying, and finally instilling 1 in 60 carbolic in spirit drops. If this method, or one of the many similar methods followed by individual otologists, fails to effect a cure within a short period, zinc ionization should be tried; it will, in certain cases, give good results, but the ear must be efficiently cleansed before its application. Too much reliance must not, however, be placed upon ionization, and provided the pharynx, nasopharynx, and nose have no infective areas (needless to say, if they have they should be cleared away) then the mastoid antrum should be explored, and it is for early exploratory operation that I would plead. If the simple methods of treatment fail, I do not think there is the least use in going on with them, for, as I have already stated, the focus of the trouble is then in the mastoid antrum, which communicates with the suppurating middle ear. There is, unfortunately, in the minds of many practitioners of medicine, certainly in those of the public, a dread of mastoid operations, surviving from the time when they were attended by a high mortality, and the only recognized methods were boring a hole in the mastoid antrum, and the so-called radical operation. The former was usually insufficient; the latter usually went a great deal too far.

In the vast majority of the more recent mastoid infections it will be found that a modified Schwartze operation will be sufficient to effect a cure. By a modified Schwartze I mean an operation that Schwartze never contemplated—namely, the removal of the entire diseased area, including sometimes the upper parts of the bridge, and especially the tip cell, and then either treating with hipp or draining, according to the condition present. The antrum and the cells may be full of pus; on the other hand there may be no pus, but the bone may be completely dead and a dry caries or osteomyelitis found. If the latter condition is present it will be sufficient to remove the diseased bone, thoroughly dry the area, and completely close the posterior wound, the patient being discharged in about ten days with primary union. In those cases which have been drained, the drain may be removed at varying periods, according to the condition, but usually the time should not be prolonged. In the more chronic cases it will be necessary to perform a modified radical operation, and for this my procedure is as follows. Having removed all diseased bone, including the bridge, down to near the tympanic membrane, I split the soft meatus, insert a large tube in the area of the obliterated mastoid antrum, close the back wound, and either carry out the necessary after-toilet through the tube or, for this purpose, remove the tube and replace it when the toilet is completed. This toilet consists of washing out the middle ear with bland substances—for example, normal saline or colloidal silver—and blowing air through. In this way all disease of the middle ear is got rid of and the tympanic membrane heals. The tube is then withdrawn, and the area, which is already granulating freely, will be entirely closed. There is no need to retain this posterior opening in the soft meatus. Such an operation should, I believe, replace the old radical one nearly always; the patient subjected to it acquires no deformity, and his hearing remains good or normal.

The student and young practitioner must be trained on new lines. He must no longer be taught that the sign of mastoiditis is a swelling behind the ear—which in the vast majority of cases should never be allowed to appear—and that the only operation short of liberating the collection of pus is to remove the entire hearing apparatus of the tympanum. On the contrary, he must be taught that the smaller operation, carried out early, should be regarded as a means of removing disease, and that the larger operation, while removing disease, should aim at conserving the function of hearing. He should also be taught that a mastoid operation properly carried out is practically never a menace to life, but as a rule can be done rapidly with first-class results, giving relief to symptoms and leaving behind no deformity. It is to be hoped that he will then appeal to the otologist much more frequently to cure the "running ears" of his patients.

* A communication made in the Section of Oto-Rhino-Laryngology at the Annual Meeting of the British Medical Association, Manchester, 1929.

TONSILS, TEETH, AND MATERNITY.

BY

BERNARD E. JERWOOD, M.D.,

MANCHESTER.

THERE is a tendency to-day to attribute many chronic illnesses to focal sepsis, and of the foci of sepsis the tonsils and teeth constitute a large proportion. Articles have recently been published by Platt,[1] Osman,[2] and Langdon Brown[3] in which infected tonsils are blamed for a large proportion of diseases of the kidney. Now disease of the kidney has always been closely associated with the toxaemias of pregnancy, which undoubtedly contribute largely to maternal mortality and morbidity. Gynaecologists, however, and others who are now writing a great deal about the dangers of child-bearing, make very little mention of septic foci, or, indeed, of anything beyond the genital tract. Professor Young[4] and Gibberd[5] have lately disagreed as to whether pregnancy can originate nephritis in previously healthy kidneys. It would appear that kidneys already strained to the utmost in disposing of poisons, usually of infective origin, are frequently damaged temporarily or permanently by the extra work thrown upon them by pregnancy. Pregnancy would not damage a healthy kidney, but is, as Gibberd puts it, "the most delicate test of renal function that we possess."

The great war demonstrated that thousands of men, presumed healthy, really belong to the C3 category. Maternity demonstrates less strikingly, but just as certainly, that the same is true of women. Unfortunately, however, the pregnant woman has to go through with her campaign and cannot be discharged as unfit, though, as the pregnancy proceeds, her unfitness often becomes obvious. It had been my experience during the few years spent in general practice to find that nearly all illnesses in connexion with pregnancy were not due to the pregnancy, but merely made to assume importance on account of the pregnancy. Chronic tonsillitis was by far the commonest underlying cause, at any rate in young women. Oral sepsis affected some of the older.

The Investigation of Focal Sepsis.

Since October, 1928, I have been engaged to a considerable extent in the examination of national health insurance patients referred for a second opinion with regard to their fitness for work. Relatively few acute illnesses are seen, and much time is naturally spent in looking for the underlying causes of ill health. In the district in which I do most of my work a high proportion of patients referred to me are either pregnant or post-parturient women. Their complaints are often vague—anaemia, debility, gastritis, bronchial catarrh, rheumatism, and tachycardia—but when these are coupled with pregnancy or lactation, it is obvious that the woman is unfit for work. Whatever a case is labelled the condition is commonly one of a low-grade toxaemia which might have passed unnoticed but for the added burden of pregnancy. Such a toxaemia might, of course, be due to a variety of causes, but in many cases the tonsils or gums appeared sufficiently unhealthy to warrant their impeachment, and ordinary clinical examination revealed no other cause.

In my investigations I have judged the infectivity of tonsils by the following criteria:

(*a*) Considerable enlargement.
(*b*) Lobulation or inequality of the two tonsils.
(*c*) The presence of large crypts or one large crater.
(*d*) The presence of pus or visible debris.
(*e*) The enlargement of the cervical glands without other obvious cause, or of the "tonsillar" gland in any case.
(*f*) The presence of any tissue in the tonsil beds after tonsillectomy.

The history is of great value, especially a history of scarlet fever, rheumatic fever, and quinsy. Leading questions may be necessary, as in the case of a woman of 52, incapacitated with rheumatism attributed to the menopause, who denied any previous illness. In answer to leading questions she admitted having had quinsies annually till she was 36, when she "outgrew them."

Oral sepsis is not so difficult to investigate in the insured class as in the wealthy. Caries or pyorrhoea is often glaring; on the other hand, complete dentures in young people are quite common. Conservative treatment of teeth is more readily available for wealthier people, and in them apical infection may do its evil work for years before its presence is discovered. But in the insured class pyorrhoea or caries runs a rapid course and leads to complete extraction before much apical or bone infection takes place, or if extraction has not taken place, the sepsis is at any rate obvious.

Results of Examination.

During January and February, 1929, 63 pregnant and 121 post-parturient women were seen. Results of complete clinical examination of these cannot be presented in a readable form. Raised blood pressure and albuminuria were often found, and as these are perhaps the most definite physical signs of toxaemia, they are given in tabular form, together with the history of tonsillitis, the condition of the tonsils, and the condition of the teeth and gums. The few other definite conditions met with are recorded in the footnotes.

TABLE I.—*Comprising only those Cases found Unfit.*

UNFIT CASES OF PREGNANCY.	Age Groups.					Total.	Per Cent.
	17-20	21-25	26-30	31-35	36-41		
Number of cases	6	18*	9†	9‡	3	45	100
... ...	5	11	9	8	1	34	76
...	5	16	6	7	2	35	80
Dental caries or pyorrhoea present	2	10	3	3	3	21	46
Raised blood pressure present	4	13	5	6	2	30	67
Albuminuria found	0	2	1	3	0	6	13

UNFIT POST-PARTURIENT CASES.	Age Groups.					Total.	Per Cent.
	17-20	21-25	26-30	31-35	36-42		
Number of cases	11	32	15	9	15	82	100
History of scarlet fever, rheumatic fever, or tonsillitis	8	22	6	4	3	43	52
Septic tonsils present	11	28	11	9	8	67	82
Dental caries or pyorrhoea present	3	14	9	6	10	42	51
Raised blood pressure present	3	8	6	1	8	26	32
Albuminuria found	3	7	3	4	4	21	25

* Includes one case with influenza.
† Includes one case with positive Wassermann reaction.
‡ Includes one case with glycosuria and one with phthisis.

A second table shows how many patients with a raised blood pressure, albuminuria, or both, also had septic tonsils, oral sepsis, or both.

TABLE II.—*Showing how many of the Unfit Cases with a Raised Blood Pressure, Albuminuria, or Both, were associated with Septic Tonsils, Oral Sepsis, or Both.*

PREGNANCY CASES.	Age Groups.					Total.
	17-20	21-25	26-30	31-35	36-41	
Cases with raised blood pressure—						
Septic tonsils	3	6	2	2	0	13
Tonsillar and oral sepsis	1	5	1	1	2	10
Oral sepsis	0	1	1	0	0	2
Cases with albuminuria—						
Septic tonsils	—	—	1	—	—	1
Tonsillar and oral sepsis	—	1	—	—	—	1
Oral sepsis	—	—	—	—	—	0
Cases with raised blood pressure and albuminuria—						
Septic tonsils	—	—	—	1	—	1
Tonsillar and oral sepsis ...	—	1	—	—	—	1
Oral sepsis	—	—	—	—	—	0
Cases with raised blood pressure or albuminuria—						
No focus found	—	—	1	2	—	3

TABLE II (*continued*).

Post-parturient Cases.	Age Groups					Total.
	17-20	21-25	26-30	31-35	36-42	
Cases with raised blood pressure—						
Septic tonsils	1	3	1	—	3	8
Tonsillar and oral sepsis	1	1	2	—	2	6
Oral sepsis	—	—	—	—	1	1
Cases with albuminuria—						
Septic tonsils	1	1	—	—	1	3
Tonsillar and oral sepsis	1	1	—	3	—	5
Oral sepsis	—	—	—	—	1	1
Cases with raised blood pressure and albuminuria—						
Septic tonsils	—	3	1	—	—	4
Tonsillar and oral sepsis	1	2	2	1	1	7
Oral sepsis	—	—	—	—	—	0
Cases with raised blood pressure or albuminuria—						
No focus found	—	—	—	—	1	1

These tables show that in nearly all the patients with raised blood pressure and albuminuria there were also present septic tonsils, and in only a very few was there oral sepsis alone. In this connexion I might add that I often found the knee-jerks absent or nearly so in patients with septic tonsils, but never in patients with oral sepsis alone. Exaggerated knee-jerks are common with oral or tonsillar sepsis. Unfortunately there were no controls, but it is significant that hardly any of the patients had had complete enucleation of tonsils. The tables also showed that raised blood pressure was more commonly found than albuminuria, especially in pregnant women; and that albuminuria occurred more often in the post-parturient than in the pregnant women.

It may be interesting here to remember Lord Dawson's[6] reference to raised blood pressure in school boys and girls. Of 650 persons between the ages of 10 and 17, 8 *per cent.* were found to have blood pressures above 130. No cause for this was discovered, and I suggest that, if a similar investigation be carried out again, special notice (including history) should be taken of the tonsils.

Summary.

The absence of controls makes definite conclusions impossible, but it is suggested that maternal mortality might be reduced by eradicating focal sepsis, preferably before pregnancy has occurred. The tonsils are the commonest site of focal sepsis in young adults, and therefore in most *pregnant women*. This is not surprising, since our present civilization encourages air-borne infections, although it has reduced many diseases spread by food and vermin. Just as influenza and nasopharyngeal catarrhs constitute an overwhelming majority of the acute illnesses met with in general practice, so chronic sepsis of the upper respiratory tract lies at the root of most chronic debilities.

INDUCTION OF PREMATURE LABOUR.

BY

ETHEL M. TOWNEND, M.D., B.S.,

HULL.

By the method about to be described I have induced premature labour 137 times. From the statistics given below it will be seen that of the cases in which the mothers were healthy and the presentation was normal, and the only abnormality was disproportion, over 85 per cent. of the infants are still alive and well, their ages ranging from 4 months to 4 years; furthermore, that without exception the mothers were discharged well and with a sound uterus and abdominal wall.

Selection of Cases for Induction.

I ascribe these good results not only to the method, but to the fact that the cases have been carefully selected. Induction is unsuitable in the presence of the severer forms of pelvic deformity with a true conjugate under 3½ inches. In 90 *per cent.* of all cases of pelvic deformity the amount of contraction is small, and a foetus of thirty-six to thirty-eight weeks' development will pass through the pelvis as easily as a full-term child will pass through a normal pelvis. In these cases induction is valuable because, if the pregnancy is allowed to proceed to term, it is then a matter of chance if the foetus can be delivered alive. In the normal case with a vertex presentation the head is usually fixed or capable of engaging by the thirty-sixth or thirty-seventh week. If there is slight pelvic contraction, and the head just fails to engage, the moulding it will receive during labour would make it still capable of passing through; but after another two or three weeks its passage would be difficult, or impossible. Such a case is best dealt with by the induction of premature labour. A second group of cases suitable for induction are those in which rotation during the thirtieth to the thirty-sixth week has failed to convert a breech presentation to a presentation of the vertex. Especially is this an indication in primipara. The third suitable group includes patients suffering from cardiac or renal decompensation, and therefore ill-fitted to withstand prolonged labour, deep anaesthesia, and shock.

Description of the Method.

A course of castor oil and quinine is first given, as suggested by Dr. Eden—that is, oil at 6 a.m., quinine gr. x at 10 a.m., 2 p.m., and 6 p.m., on alternate days for three days. This method is often sufficient in cases near term, but not before the thirty-seventh week. Sometimes the head is driven into the brim, and although actual labour does not start the case can be allowed to go to term. The quinine is only given if the patient is healthy.

If labour does not begin or the head fails to engage, the patient is prepared as for a general anaesthetic, and thirty minutes before the operation a hypodermic injection of hyoscine *co.* (B) (Burroughs Wellcome) is given. The lithotomy position is used; the shaved vulva is bathed with a 1 per cent. solution of picric acid, a vaginal speculum introduced, and the exposed cervix swabbed with 1 in 2,000 mercury perchloride lotion; a lysol douche is then given. A Jacques oesophageal bougie is now held in the left gloved hand, and two fingers of the right are passed up to the cervix. The tube can now be guided along the palmar surface of these fingers into the cervical canal, and so into the uterus. Care must be taken to ensure that the whole tube is passed within the internal os. The cervix is not injured, because no vulsellum forceps are used. If the cervix is high up and small a little open ether will make the operation easier by relaxing the levator ani muscle. There is practically always sufficient dilatation to allow the tube to pass. No further attention is required beyond a daily douche, and if the tube presents below the head it is best to withdraw it when the cervix is half dilated.

The advantages of this method are, first, that it is reliable—I have only had to reintroduce the tube once; secondly, that it is quite painless during the waiting stage, unlike the gum-elastic bougies which press into the posterior vaginal wall; and, thirdly, that there is no ladder leading from the vagina into the uterus up which infection may pass. The time from the introduction of the tube to the delivery averages about twenty hours.

Results.

Total induction—1924 to August, 1929	137
Maternal mortality	*nil*
Maternal morbidity—light pyrexia	2
Infants: Period 1924-28 inclusive. Condition in April, 1929.

Died	1

My thanks are due to Dr. Albert Daley (medical officer of health for Hull) for permission to publish this paper, and to Dr. Gilchrist, who has obtained the after-histories of the infants for me.

Memoranda:

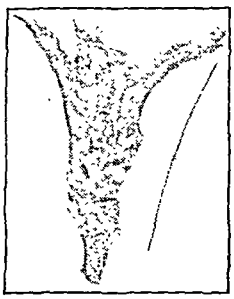
MEDICAL, SURGICAL, OBSTETRICAL.

FOREIGN BODY PERFORATING THE SMALL INTESTINE.

THE following case, which occurred in my hospital practice early this year, seems worthy of record.

A man, aged 23, was admitted to the Dunfermline and West Fife Hospital on March 1st of this year as a case of subacute appendicitis. His history was as follows.

Three months previously, while at work, he was seized with sudden pain at the umbilicus and felt sick, but did not vomit. He was brought home from work and was seen by his doctor, who diagnosed appendicitis. His temperature was 99° F., and he had tenderness in his right iliac fossa. He was off work for three days. Since then he had had frequent similar attacks of umbilical pain, usually coming on during his work, and he had to desist from work for ten to fifteen minutes and rest till the pain passed off. Three days prior to admission to hospital he had a similar but more severe attack which necessitated his staying away from work. His doctor was again called in and sent him into hospital. During the whole of this time his bowels had been regular and he had no urinary symptoms.



Photograph showing wire and omentum

On admission the patient did not look ill. The temperature was 100° F., and the pulse 88. His tongue was clean and moist. Abdominal examination revealed slight tenderness on deep pressure over McBurney's point. No rigidity and no hyperaesthesia was present.

His condition was diagnosed as appendicitis (catarrhal). At the operation, which was performed on March 4th, the abdomen was opened by a right rectal incision displacing the rectus inwards. There was a fair amount of free serous fluid in the peritoneal cavity. The caecum was delivered and a slightly inflamed appendix removed.

The duodenum and gall-bladder appeared normal. The great omentum was seen to be adherent in the pelvis, and on exerting traction on it a loop of ileum was delivered. To the apex of this loop a narrow strip of omentum was adherent, and protruding through this was a piece of wire, which was partly inside the ileum and partly covered by omentum. The wire was pulled out and the omentum, which was intimately adherent over the perforation in the bowel, was divided. The perforation was infolded by a purse-string suture. Several light adhesions of omentum to neighbouring loops of ileum were divided and the abdomen was closed. The wire, which was of the thickness of a darning needle, measured two inches in length.

The patient made an uneventful recovery and was discharged on March 12th.

The interesting features of the case are: (1) How the patient managed to swallow a piece of wire two inches long without being conscious of doing so. (2) The site of the perforation in the pelvic ileum; why the wire should be arrested here is difficult to explain. (3) The efficient method in which Nature, by means of the omentum, was dealing with the emergency. (4) The ease with which the condition might have been missed at the time of operation.

J. M. BLACK, M.B., Ch.B., F.R.C.S.Ed.,
Honorary Surgeon, Dunfermline and West Fife Hospital.

RETENTION OF URINE CAUSED BY FAECAL IMPACTION.

I THINK the following case is of sufficient interest and rarity to merit publication.

I was called out to see a boy, aged 3½ years, who had been having severe colicky pains in the abdomen all night and that day. As he had not vomited the mother had not sent for me before. On examination the cause of pain was obvious, the bladder being distended up to the umbilicus. I found a well-marked phimosis and took the child straight into hospital. A circumcision was performed, and an attempt made to catheterize the bladder. No instrument could be passed, and, suspecting a calculus, a finger was introduced into the rectum, which was found to be filled with hard faeces. After a large quantity of this material had been removed, a catheter passed freely into the bladder.

I have heard of this occurring in a female child, but never in a male.

J. MYLES MITCHELL, M.B., B.Ch.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

WESTMINSTER AND HOLBORN DIVISION.

Obesity and Health.

AT a general meeting of the Westminster and Holborn Division, on November 19th, which was preceded by a dinner at Romano's Restaurant, a paper was read by Dr. W. F. CHRISTIE on obesity and the ideal figure. Mr. DUNCAN FITZWILLIAMS, chairman of the Division, presided.

Dr. Christie described corpulence as a deviation from the normal, an aberrant nutritional state. He confined his remarks to the simple or exogenous form, as being the only one from which those whom he was addressing were likely to suffer. In recent times there had been a "slimming" craze, which the profession was apt to decry because it was carried out by normally proportioned people who should have nothing to do with it; but so far as stout persons were concerned it was all to the good. Too much fat on the body made for sluggishness, impaired initiative, and destroyed effort; it involved personal discomfort, detracted from appearance, and perhaps furnished a reason for a premium to the assurance company. Every physician, surgeon, orthopaedist, and gynaecologist was aware of its disadvantages. Whenever the intake of energy in the form of food exceeded the output in the way of physical—not intellectual—activity, corpulence might develop. The theory had been advanced that over-fatness was due to a lowering of the metabolic processes consequent upon defective secretion, and certainly there were people who could eat what they liked and never fattened, while others apparently consumed little and yet became stout. No evidence of endocrine dysfunction, however, had yet been found to account for these defects; it might be that the glands of internal secretion, when strong and active, could prevent the accumulation of fat whatever was eaten. There were three periods in women's lives when they tended to become stout: after the attainment of full growth, after childbearing, and at the menopause. There were two such periods in the lives of men: after marriage, and after the attainment of worldly prosperity. The less active one became, the less one should eat. Nature was inexorably counting the calories, though her children might be thinking of other things. Theoretically the right quantity which a man ought to carry was that which allowed the freest physical activity compatible with sound health, and left him a trifle over for use in emergency. There were four methods in vogue, no one of them sufficient in itself, for making an independent estimate of what the ideal figure of a particular person should be—namely, inspection and palpation of skin and subcutaneous tissues; tape measurements, to ascertain whether the sizes of certain parts of the body were in proportion; weight measurements in comparison with height, and, finally, assessment of ideal weight by means of formulae based on the actual weight, length of trunk, and chest measurement. In the perfect figure other things besides adipose tissue had to be considered. Muscles, for example, must be well, but not over developed.

The "perfect female figure" was apt to vary with the fashion plate of the moment, but in the case of men the figure of the athlete was generally regarded as the ideal.

Dr. Christie spoke of dieting in athletic training. The modern diet for general athletics comprised all ordinary foods, but in somewhat different proportions from that of everyday life. Its calorie value per day was round about 4,000. An athletic diet must contain an unusually large proportion of protein, while some carbohydrate elements were eliminated. Cross-Channel swimmers made free use of fattening foods, and took some form of sugar during the swim. It was noteworthy that all successful aspirants to Channel honours had been corpulent. When it came to reducing fat, Dr. Christie was not in favour of exercising the corpulent. There were two main types of dieting for thinning purposes. The rapid type, in which from three to six pounds of fat were lost each week, and which involved complete or partial fasting or freak diets, was not to be recommended. On the other hand, the slow method, by

which from one to two pounds were shed weekly, had proved useful. After ten weeks, when eighteen or twenty pounds had been dissipated, it was wise to return for a couple of weeks to a maintenance diet, and thereafter the reducing one might be resumed. For the construction of a reducing dietary the requirements per day of the ideal weight should be calculated and translated into terms of food; enough protein should be given to prevent muscular weakness, and vitamin and salt-containing foods to maintain good health, and the carbohydrates and fatty elements should be reduced by 1,000 calories in order that 4 oz. of fat might be drawn upon each day for the supply of energy. Bulky foods of low calorie content should be given, and no purpose was served in giving foods which were distasteful.

Reports of Societies.

TREATMENT OF EXOPHTHALMIC GOITRE.

AT a meeting of the Royal Medico-Chirurgical Society of Glasgow, on November 1st, with the president, Dr. JOSHUA FERGUSON, in the chair, a discussion took place on exophthalmic goitre.

Dr. JOHN GRACIE, who spoke on the medical aspects, said that the treatment of this condition was at the present time a highly controversial matter. According to the Registrar-General's returns, an average of 400 deaths occurred annually from Graves's disease; it was estimated that this number represented only 25 per cent. of those who suffered from it, others dying from some intercurrent malady. Until recent years the treatment of the disease had been almost entirely in the hands of the physician; medical treatment had made no appreciable advance, and no specific remedy had yet been discovered. He pointed out the difficulty of differentiating cases of true exophthalmic goitre from those which presented all the classical signs of the disease, but which had only a short period of toxicity, recovery following as soon as the exciting cause was removed—spontaneously or otherwise. He believed that many such cases never came under observation, and that those which did so increased unfairly the percentage of medical cures. Consideration of the normal activity of the thyroid gland at various periods of life gave a physiological basis for this opinion. There were periods or conditions of life when abnormal stimulation might cause the gland, previously adequate and normal, to function deficiently or excessively, producing an internal secretion imperfectly iodized or otherwise toxic, which gave rise to the syndrome of exophthalmic goitre or of toxic goitre. For these reasons, and because of the difficulty in classification, he considered that all early cases of hyperthyroidism should be kept under medical observation. Delay was not necessarily a barrier to operative treatment should this be decided on later, since the most severe cases with cardiac failure, if adequately prepared, made almost dramatic recoveries. The recognized forms of medical treatment were two—namely, general and iodine therapy. The first included removal to a cool bracing climate, rest, sedatives for mental excitability, atropine for excessive sweating, and digitalis and allied drugs for tachycardia. Cold applications to the neck, the serum of thyroidectomized sheep, and the milk of thyroidectomized goats had been recommended. Insulin had been used because of the increased metabolism. Many physicians advocated the use of σ rays, but the speaker's experience with this form of treatment had been disappointing. Bromides had some effect in checking nervousness and anxiety, but none on the cause of the nervousness, and their action was therefore purely symptomatic. Digitalis acted by stimulating the vagus roots in the medulla, but the cardiac slowing was not seen under experimental conditions when the vagus was paralysed with atropine, nor was it seen clinically in febrile conditions and in exophthalmic goitre. There was no clinical or experimental evidence in favour of its employment. Since its discovery as an element in 1812 iodine had been in more or less constant therapeutic use, but it had no scientific basis until Kendall isolated from the thyroid a crystalline substance called thyroxine, which was found to contain 65 per cent. of iodine. It was estimated that the total amount of thyroxine in the tissues, exclusive of the thyroid, was about 14 mg., and that the thyroid secreted from 1.0 to 1.5 mg. of thyroxine daily. To produce this quantity of hormone, 0.33 to 0.5 mg. of iodine must be available. A shift of 1 mg. of thyroxine was accompanied by a rise or fall of 2 or 3 per cent. in the basal metabolic rate, so that it was possible that a rise of, say, 25 per cent. in this rate in a case of hyperthyroidism could be accounted for by an increase of 12 to 15 mg. in the thyroxine output. In the absence of methods of estimating the daily output, it was not yet possible to determine how much, if any, of the increase was due to an abnormal amount of normal thyroxine. The work of Marine and Rogoff showed that iodine was taken up and fixed in the thyroid within a few seconds; the formation of pharmacologically active iodine was, on the other hand, a slow process, and it showed wide variations even in normal subjects. The two processes were probably distinct, and the rate of activation of the iodine was controlled by the amount of chemical nucleus available, and not by the amount of iodine, when that element was present in normal amounts. Graham's work showed that the iodine content of the thyroid was no index of its activity. Iodine was probably present in two forms, an inactive and an active. It might be assumed that while administration of iodine would influence the inactive form, it would have no definitely controllable effect on the pharmacologically active substance. Until a method of varying the output of this active substance was discovered there could be no hope of curing hyperthyroidism by medical means. In well-marked cases of exophthalmic goitre intensive treatment with iodine resulted, in a few days, in a marked amelioration of symptoms and general improvement, but following this there was a recrudescence of symptoms, and further iodine treatment did not result in the same marked improvement. This applied also to patients who had been given iodine in small doses, and cases so treated were handicapped in subsequent operative treatment. It would appear that there was an iodine saturation point which converted an abnormal thyroid secretion into one which was normal, both qualitatively and quantitatively. Administration beyond this point seemed to have an injurious effect, and it was Dr. Gracie's opinion that in the present state of knowledge iodine should not be used as a routine treatment in cases of hyperthyroidism. With regard to operative treatment Dr. Gracie said that the immediate risk of death and the later risk of myxoedema had to be placed against the risk of permanent cardiac damage, mental impairment, prolonged invalidism, and curtailment of life. Many reports of successful operative treatment in the Mayo Clinic and other American medical schools had encouraged the speaker to give surgical treatment a fair trial; this trial had produced results which he and Mr. Renton had no reason to regret. The cases selected for operation had all been established for at least a year, and they were, with one exception, the worst cases admitted to their wards. All the male patients had either septic teeth or septic tonsils; this factor of infection was absent in female patients, and in them psychic trauma seemed to be the predominating predisposing cause. Five of the fourteen cases treated surgically were in a condition of auricular fibrillation when they underwent operation; in none did the fibrillation disappear spontaneously. Three of the five were treated with quinidine sulphate after recovery from the immediate effects of the operation. The case which was not specifically treated continued to fibrillate, while the other three had been restored to normal rhythm. Dr. Gracie had found that an average of 10 minims of Lugol's solution thrice daily was sufficient to bring the patient into a satisfactory state for operation in from seven to ten days. Conditions were regarded as suitable for operation when the pulse rate had fallen to between 80 and 90 per minute, and when there was a diminution in the nervous symptoms with a distinct improvement in the general condition. Tabulated statistics of his own cases

showed that of the fourteen patients treated medically only one was dismissed well, while eight of the fourteen patients treated surgically were dismissed well. At the present time the most successful treatment for exophthalmic goitre was a combination of medical and surgical treatment, with co-operation between physician and surgeon.

Mr. J. MILL RENTON, dealing with the surgical treatment of exophthalmic goitre, said that in order to justify surgical intervention in such a disease it was essential that (1) the operative risk should be small, (2) the results should be better than could be obtained by medical treatment. In recent years the mortality had been greatly reduced by the use of more suitable anaesthesia, special preparation of the patient, and an improved operative technique. In his experience the most satisfactory anaesthetic was gas and oxygen. It was important to choose the optimum time for the operation, to remove any septic foci that might be present, to give a course of Lugol's iodine for ten to fourteen days, and to inspire the patient, as far as possible, with a feeling of optimism and confidence about the operation. There was no better method of doing this than to get a patient who had been operated upon to talk to the one awaiting operation. The most important points in the performance of the operation were: (1) good exposure of the gland; (2) control of haemorrhage; (3) avoidance of injury to the recurrent laryngeal nerves and parathyroids; (4) removal of sufficient gland tissue to cure the symptoms; and (5) drainage of the operation area. Mr. Renton said he was in the habit of using the usual collar incision; the pre-tracheal muscles were first separated in the middle line right down to the thyroid, and were then either retracted or divided. He preferred to divide them at least on one side. The superior thyroid artery was ligatured and divided, and the lobe dislocated. The inferior artery could not be so safely ligatured on account of the proximity of the recurrent laryngeal nerve, so that the usual practice was to cut through the thyroid itself; this involved a good deal of bleeding, which had to be controlled by pressure forceps placed on friable tissue. It was sometimes possible to place an elastic ligature round the posterior aspect of the lobe and then remove it without any bleeding. Haemorrhage was thereafter controlled by means of a purse-string suture. He aimed at removing the entire gland, except for a small portion on each side of the trachea. The removal of only one lobe, while it often caused considerable improvement, usually involved a further operation later to complete the cure. In cases where the patient was very ill it might be necessary to remove only one lobe, but he thought that the other lobe should be taken away as soon as the patient was well enough. The area on either side of the trachea, where some thyroid tissue was left, should be drained. The operation was generally followed by a rise of temperature and an increase of pulse rate; but this usually subsided in three to six days. Ten minims of Lugol's iodine was administered as soon after the operation as possible, and was continued thrice daily. Plenty of fluid should be given during the first few days. There were twenty-one cases in his series, and the ages of the patients ranged from 15 to 57 years, with an average age of 34.4 years. The average duration of the symptoms before operation was just over two years. Fifteen of the cases had been operated on a year or more ago, three cases about five months ago, two cases four months ago, and one case only two months ago. Fourteen were well, five improved, one not much better, and one had died. Of the five cases which had improved, three had partial thyroidectomy, and it was hoped that further removal of thyroid might complete their cure. One of the most striking features following operation was the rapid subjective improvement, but exophthalmos, particularly if it had been present for some time, was slow to disappear completely. In conclusion, Mr. Renton thought that his series appeared to show that if sufficient thyroid substance was removed patients had a good prospect of returning to a normal existence within a comparatively short period.

Dr. GAVIN MCCALLUM demonstrated a series of histological preparations taken from the material removed at operation by Mr. Renton.

Dr. G. A. ALLAN remarked that while the series of cases recorded was relatively small, the numbers were sufficient to show that operation risk was not great. It was desirable to diminish the time required for cure as far as possible, and if operation could be shown to be associated with little risk to the life of the patient, then it was to be preferred to medical treatment. Certain factors in the preparation of the patient for operation were of importance in minimizing operation risk. If the heart was acting regularly but rapidly he did not think digitalis was of any value for reducing the rate. Iodine, the only drug of any use for this purpose, acted, presumably, through the sinus node—producing its effect primarily on the thyroid and, through it, on the sympathetic. When auricular fibrillation was present the ventricular rate could be reduced by digitalis.

Mr. J. RUSSELL insisted that exophthalmic goitre was a constitutional disease, dependent on some unknown stimulus to the thyroid gland. He thought that physicians should agree to consider the question of operation in these cases within the first six months of medical treatment being commenced, and should try to hand over these cases before cardiac changes occurred. Once they had watched the removal of nine-tenths of both lobes of the thyroid gland, and followed these cases up for a very few weeks, they would be convinced that operation was the right treatment; but the mortality could only be kept low by submitting to operation early.

Mr. R. MAILER said that cases of not more than twelve to eighteen months' duration reacted well to iodine. In America most of the cases operated upon were of this type, generally of less than one year's duration, but in Great Britain early operation was exceptional, and many of the cases treated surgically were late ones, sometimes of five to ten years' duration. Iodine had little effect on such patients. He thought the best way to deal with such cases was to remove only one lobe of the thyroid, thus reducing the operation risk. After two or three months' rest and iodine treatment a certain degree of fibrosis of the gland resulted, and removal of the second lobe was thus easier.

Mr. R. BARCLAY NESS described a case under his own observation in which there had been great improvement after treatment with rest, iodine, and x rays. All the symptoms of exophthalmic goitre had disappeared except tachycardia and sweating. Later there had been a relapse, and the patient was successfully operated upon by Mr. Renton.

Dr. J. FERGUSON agreed that, given adequate preparation by the physician, and a high degree of technical experience in the surgeon, a distinct advance toward the successful treatment of the disease could be made. But even those gratifying results did not justify at present a universal recourse to thyroidectomy as a cure of hyperthyroidism. Until the surgeon could assure the patient that the issue of his procedure was as safe as that, say, of appendicectomy, many cases would, reasonably enough, be left to medical treatment. Radiotherapy was not discredited, and the use of minimal doses of iodine was not limited to the pre-operation stage, but could be continued with established benefit and satisfactory result over a long period.

Dr. GRACIE, in reply, said he believed that there was a local action of digitalis through the node which produced a slowing effect on the heart. The effect of iodine was to overcome toxic processes, and this produced a reduction in the rate of the heart which was much greater than that which followed the use of digitalis. With regard to the question of restoring normal rhythm before operation, he thought that this was desirable but not essential. The operation should be done at the time of the drop in the pulse rate which resulted from iodine treatment; if this period was missed there was never as good a chance of success later. For this reason he thought it was undesirable to delay till the effect of quinidine was tried; it was better to restore the normal rhythm after operation. He had found iodine useful in lowering the pulse rate even in old-standing cases. The patients in his series had been ill on the average for two or three years, yet nearly all of them responded to iodine, though only temporarily.

INFECTION OF THE GALL-BLADDER.

AT a meeting of the Forfarshire Medical Association, held in the Medical School, University College, Dundee, with Dr. J. S. Y. ROGERS, the president, in the chair, the opening address for the session was delivered by Professor D. P. D. WILKIE, Edinburgh, who took for his subject gall-bladder infection and its sequels.

Professor Wilkie described the steps which had led up to the present-day conception of gall-bladder disease, which was based essentially on the pathology of the living as revealed at operation; he illustrated by lantern slides the main points in the anatomy and physiology of the gall-bladder which the intensive research of the last few years had brought to light. Reference was made to the recent work of Ivy and Oldberg, which had demonstrated the presence of a gall-bladder hormone. These observers, using a "purified" secretin, which was extracted from the mucosa of the upper part of the small intestine, had produced gall-bladder contraction by intravenous injection, and by cross-circulation experiments had proved that it was a blood-borne hormone. The relationship of gall-stones to cholecystitis was discussed, while primary stone formation in the case of the chole-terin solitaire and the pure pigment calculi was admitted, emphasis was attached to the primary clinical importance of the inflammatory factor. Clinical and experimental evidence was cited in favour of the view that chronic cholecystitis was in the great majority of cases a blood-borne streptococcal infection, and the investigations of Illingworth and of A. L. Wilkie were reviewed. Professor Wilkie said that the streptococcus concerned did not appear to be a specific type, but merely one which had acquired an elective affinity for growth in the gall-bladder. The essentially intramural character of the infection and the evidence of absorption which the regular presence of the coccus in the cystic lymph gland displayed gave support to the view that the gall-bladder might be an important focus of infection. Radical surgery was at present the only certain means of eradicating such infection when it was once fully established. Except in acute suppurative cases in bad subjects, removal of the gall-bladder was the only logical treatment. The sequels of neglected cholecystitis, both local and metastatic, were discussed, and the advisability of investigating gall-bladder function in arthritis, and even in renal cases, was emphasized. The advantages and limitations of cholecystography were pointed out, and allusion was made to the significance of the gastric disturbances in early cases.

CONCOMITANT CONVERGENT SQUINT.

AT a meeting of the Liverpool Medical Institution, held on December 5th, Mr. BERNARD CHAVASSE read a paper on the comparative anatomy and psycho-pathology of concomitant convergent squint.

Mr. Chavasse said that only in rare cases was muscular paralysis the cause of squint. The fusion faculty theory introduced a *deus ex machina*—comforting, but hardly explanatory in the scientific sense. The hypermetropic theory of Donders was, however, important; properly to assess its value it was necessary to know the incidence of the various degrees of hypermetropia in *normal* children at the age of incidence of squint, and to establish in each degree a ratio with the corresponding figure for squinters. If this was done it was seen that the incidence of squint rose in geometrical progression as the degree of hypermetropia progressed arithmetically. Notwithstanding this mathematical relation between definite degrees of hypermetropia and ordinary squint, Donders's theory failed to account for cases in which the hypermetropia was no more than normal for the age of the patient, or within the physiological limits of compensatory divergence. Moreover, it failed to account for the cases of convergent squint actually myopic from onset, and it left unexplained the disproportion between the degree of hypermetropia and the degree of convergence. In fact, there was no proportion between them at all. Avoidance of diplopia could hardly be operative in cases in which the acuity of the squinting eye was, from the first, below the diplopia threshold. Further, the theory offered no explanation of the mechanism by which most hypermetropes escaped squint, or of possible anomalies of the same mechanism which might precipitate squint. But though the theory was only partially valid it would occupy a place of primary importance in any complete theory.

Mr. Chavasse then proceeded to outline an *evolutionary* approach to the problem of squint. Contrary to the widely accepted belief, stereopsis was no perquisite of the primates. He described conjugate movements and monobjective binocularity in fishes, and the primitive mechanism by which, in his view, stereopsis was attained (in the almost total absence of convergence) by the establishment of functional retinal correspondences related to some precise activity (such as the engulfing of a prey situated at an invariable distance from the snout). In the development of species the perfecting of stereopsis was effected by convergence of the eyes, which approximated the optical axes to the stereoscopic axes, thus eliminating optical errors and enlarging the stereoscopic field. All kinds of compensatory mechanisms and habits, such as the assumption of the erect posture, were evolved merely to enable convergence to proceed unhampered by the implied limitation of panoramic vision.

Of the total ocular correspondence which was the foundation of stereopsis, retinal correspondence was perhaps the most important. It was of various grades; in fishes and most mammals it was functional; in tarsius and the chameleon the correspondence was centred in a structural macula, while in birds and primates it was preeminently foveal. There was nothing in the foveae of the primates to give them the exclusive right to stereopsis. Most birds had two foveae in each eye, one for stereopsis, the other for acute vision laterally. Foveae and maculae were widely distributed, though not always on the stereoscopic axis as they were in birds, primates, the chameleon, and tarsius; many reptiles had them; owing to the dominance of the foveae, bifoveal correspondence, as contrasted with lower grades of retinal correspondence, was perhaps of special importance in the phylogenetic arrest of convergence. The arresting mechanism became specially centred in them, and might not function without the pair of them. In the mammalia bifoveal reactions were of recent evolution only, which might be one reason for their instability, at all events in early life, quite apart from ordinary developmental instability.

The last leg on which this "primatial perquisite" theory had to stand was an old but erroneous idea about the function of the optic chiasma. The variations (hemidecussation, etc.) had no bearing either on unqualified binocular sensation or on stereopsis; but in animals whose purely monocular field was very small hemidecussation afforded opportunity for reducing the nervous connexions essential for the proper movement of the globes.

Phylogenetic convergence was recapitulated in human embryology; but the bifoveal reactions, at once the goal and the limit of convergence, were attained, as in other animals, by a final muscular convergence; the physiological basis of which was an inherited mechanism far older than that of the mammalian fovea. An ancient sequence was pursued. Thus, a stimulus incident monocularly and peripherally led to monocular fixation; this led to convergence; this in turn led to retinal correspondence, which led to the maintenance of an ocular posture. The whole system effected a total ocular correspondence with reference to the object regarded, and, according to which of the component correspondences was at fault, there issued squint of various kinds—paralytic, concomitant, etc. The correspondences were paired (as between the two sides), some sensory, some motor. There were also crossed correspondences, first between sensory and motor of similar pairs (as between one internal rectus and the other), and, secondly, between sensory and motor of different pairs. The crossed correspondences were reflex; the paired correspondences were anatomical. Within this system one distinguished a *convergence reflex*, the stimulus to which was adequate even if monocular; the ensuing convergence *reflex* (in man equilibrium by a *retinal correspondence reflex* (in man pre-eminently bifoveal), the stimulus to which was necessarily binocular. The retinal correspondence, or bifoveal, reflex was a po-tural reflex.

On such a scheme the concomitant convergent squint of ocular inequality found a ready explanation, quite apart from its usual coincidence with degrees of hypermetropia (1.0 to 3.9) which were normal for children at the age of onset of squint. As regards myopia it was possible that adequate figures might establish a relation similar to that observed in hypermetropia. If it was remembered how rare myopia was at this age, and the considerable percentage of persons with convergent squint who were myopic from the first, the labour involved in collecting a sufficient number of these uncommon cases might not be in vain. Myopia would act by interfering with the bifoveal reflex at all distances beyond the far point. The cases of squint associated with hypermetropia abnormal for young children—4 D and over—might be regarded as initiated by a primary convergence from exhaustion of compensatory divergence. The image in one eye being thrown completely off the fovea, a gross retinal non-correspondence resulted, so that the convergence reflex assumed control.

The complexity of the reflexes involved in stereopsis, and their dependence on consciousness, suggested an examination of concomitant convergent squint from the standpoint of psychology. In this way we might discern the operation of an instinct, *the stereoscopic instinct*, which was a specific innate tendency comparable to other instincts as regards age of onset, early instability (inco-ordination), acquired stability, decay, and liability to perversion by frustration in the period of inco-ordination. In such a view concomitant convergent strabismus was a postural perversion which expressed the attempt of the frustrated stereoscopic instinct to attain consummation by the immemorial means of convergence. The value of such an approach to the problem of concomitant convergent squint was that it set us free to search for further causes of ocular non-correspondence, and especially for causes of bifoveal non-correspondence, as well as for any functional or psychological factors which might frustrate the stereoscopic instinct in the early years of life.

RADIOTHERAPY IN SKIN DISEASES.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on December 6th, with the president, Dr. R. J. ROWLETTE, in the chair, Dr. W. G. HARVEY read a paper on the effects of *x* rays and ultra-violet radiation in the treatment of diseases of the skin.

In lupus vulgaris, said Dr. Harvey, a single dose of *x* rays was often of great value in treating an ulcerated lesion or a verrucose patch, but great caution should be used on account of the risk of carcinoma developing; when cancer had developed after *x*-ray exposure on a lupus patch, *x* rays had no retarding influence upon the growth of the tumour. In all other types of lupus vulgaris, ultra-violet irradiation had supplanted other forms of treatment. Irradiation should be general as well as local. Lupus erythematosus did not benefit from any kind of irradiation. Apart from their value in the treatment of *malignant growths*, *x* rays had a place in dermatology in the treatment of lichen planus, and other conditions—for example, the *eczema nuchae* so often seen in elderly women—in which the skin became lichenified; its application was often followed by marked relief from pruritus. In psoriasis *x*-ray treatment could bring about the disappearance of resistant patches, but it was possible that the same result could be achieved just as well by soap. In tinea tonsurans he preferred *x* rays to thallium acetate as a depilatory, except perhaps in very young children, as the chances of success were better. Ultra-violet radiation undoubtedly helped to clean up and heal ulcers and many superficial inflammations of the skin, but again it was possible that just as much success might follow energetic local medication and the employment of any other simple tonic (for ultra-violet light was certainly a general tonic). He deprecated as dangerous the use of *x* rays in all conditions which would yield to simple treatment, and touched on the ludicrous claims which were made for ultra-violet therapy in conditions such as herpes zoster, in which as a general rule no such treatment at all was needed.

DR. E. T. FREEMAN referred to the dangers of *x* rays, and said he thought their use for diseases which were not in themselves dangerous was a thing to be deprecated. Bad results frequently did not appear for two years after treatment, and patients who had been refused a second course of *x* rays sometimes went to a different radiologist and received treatment, with disastrous results. Cases of lupus which were septic could be considerably improved by *x*-ray treatment, but it was necessary to employ other forms of treatment as well. He thought the best treatment was to leave the patient under a carbon-arc lamp for some time, and then pick out the lupus nodules with an electric cautery. One observer had stated that this was the only treatment for lupus that had any effect at all. It was a treatment which took a long time, but he thought it was worth it, and felt that a long time, as measured by a couple of hours, was very little in a disease such as this.

DR. P. MACCARVILL said that his experience of treatment by these methods corresponded with Dr. Harvey's. There was no doubt about the value of ultra-violet therapy in lupus, especially of general irradiation, by which many patches of lupus would disappear without any other treatment. In the ulcerative form of lupus he looked on *x* rays and ultra-violet light combined as the best form of treatment. This method produced an excellent effect in cases of lupus of the mucous membrane, which before the introduction of ultra-violet light therapy were the most difficult to treat. He did not apply ultra-violet radiation in cases of psoriasis, but thought that possibly between attacks such treatment might delay their onset. He regarded *x*-ray treatment in ringworm of the scalp as being much more reliable than treatment by thallium. He wondered how it was that ultra-violet light was so valuable in the treatment of *x* rays or radium burns.

URTICARIA PIGMENTOSA.

DR. W. G. HARVEY showed a girl, aged 9, with urticaria pigmentosa. The attacks had begun when the patient was about eighteen months old. There was now no urticaria, only urticaria pigmentosa. This disease generally began in very early childhood, and occurred in the form of true urticarial attacks. As a rule the condition cleared up when adult life was reached, but not always. The microscopic sections were typical of the disease, showing an enormous number of mast cells heaped round the vessels of the glands.

DR. M. DRUMMOND said that urticaria pigmentosa was very rare. One of the best-known American dermatologists had stated recently that only about 200 cases altogether had been recorded, and that in the last twelve years in Philadelphia he had only seen about six cases.

PRE-OPERATIVE TREATMENT.

AT a meeting of the Aberdeen Medico-Chirurgical Society, on December 5th, with the president, Dr. CHARLES FORBES, in the chair, Dr. J. ROSS MACKENZIE opened a discussion on the pre-operative preparation of the surgical patient. The lecturer considered at length the place of the anaesthetic service in relation to surgery, and maintained that the anaesthetist should have ample opportunity to share in the evaluation of surgical risk in individual cases. In this connexion he discussed the importance of Moot's index of operability amongst other tests of this nature. He then dealt with pre-operative medication, laying most stress on the question of atropine, and discussed fully the arguments for and against pre-anaesthetic starvation and purging. He himself was strongly of the opinion that purgation was harmful, and that dehydration and depletion of glycogen stores were to be avoided. Dr. Mackenzie then indicated the criteria for the selection of the most suitable type of anaesthesia in special cases. He thought that hyperventilation with carbon dioxide during the administration of the anaesthetic was of great value as a *prophylactic* against post-operative respiratory complications. Mr. F. K. SMITH, Mr. W. ANDERSON, Dr. MAGEE, Mr. COLT, Dr. LYALL, and others contributed to the discussion, and the CHAIRMAN conveyed the thanks of the society to the lecturer.

Reviews.

SURGICAL DISEASES OF THE THYROID.

THERE are three tests by which a book is to be judged: the intent of the author, the worth of that intention, his success in achieving the purpose. Dr. EBERTS's *Surgical Diseases of the Thyroid Gland*[1] stands every test. It is therefore a good book. Dr. Eberts's idea was to present the whole subject within reasonable compass; the subject is one of the most important in surgery; he has brought to the successful accomplishment of the task experience, knowledge, and wisdom. No previous experience is neglected. It is mentioned either in the text or in formal sequence at the end of every chapter; it receives judgement and decision. A careful reader must agree with the initial claim so admirably—except for one sentence—expressed by Edward Archibald, the author's "friend and colleague," that the number of patients forming the basis of the study is ideal, not the multitude that creates confusion nor the paucity that leads to false conclusions. The reader will also be convinced that in no other thyroid clinic has there been a more careful study of histories, more complete examination in the laboratory, more persistent and rigid scrutiny of results. The work is based on 2,250 cases, of which 1,050 were treated surgically, and no case is included which was not under observation for a year after treatment.

The book is divided into two parts. In the first, the embryo is considered; then the anatomy, histology, physiology—normal and abnormal—and pathology of the adult gland. The second part is clinical; nothing pertinent is omitted, and one does not lament the absence of a dissertation upon problems yet unsolved. All is included within the measure of 238 small pages. The book is interesting, exciting even, easy to read, because it has style; that is, Dr. Eberts has an important thing to say, and finds words suitable for saying it. It is comfortably free from that pseudo-scientific jargon which so many writers on medicine employ, merely because their own minds are neither scientific nor clear; and yet, one could well spare such words as "electrocardiographic," which suggest a chemical formula rather than human speech. If any fellow-worker desires to know the best that is thought, known, and done, here is the place to find it. But the scrupulosity of the author in awarding credit to the various elements in his clinic has been somewhat overdone. To mention ten persons diffuses the interest and detracts from his own authority. The coherence of a clinic is always understood. Nor does it seem necessary to parade a "laboratory in Vienna," merely because certain photographs of tissues were made in that place, as a matter of routine, by one of Dr. Eberts's assistants when he was a student there. Besides, the photographs are not very illustrative—there are tissues, microscopes, and cameras in the Montreal General Hospital and at McGill.

Dr. Eberts is himself a master, he might as well admit it. Modesty and reticence are virtues. When pushed too far they present the appearance of self-depreciation. That has always been a fault in the medical profession of Montreal. They might remind themselves occasionally that the Montreal General Hospital, from which this work emanates, was the first place in America to receive and nourish the European tradition of medicine, drawn from Edinburgh, through Leyden, which in turn derived it from London—the first hospital in America to admit students within the wards. They might remind themselves, too, that McGill itself, as a university and not as a medical school alone, was created out of the Montreal General Hospital, and that from both arose the Royal Victoria Hospital. Erasmus learned Greek at Oxford, and taught it in Cambridge; Osler learned his medicine in McGill, and carried it to the United States. This work of Dr. Eberts will establish his own clinic; it will help to disclose many other clinics in Montreal equally great, and remove that Ephesian nescience which has too long prevailed. A. M.

[1] *Surgical Diseases of the Thyroid Gland.* By E. M. Eberts, M.D., Surgeon to the Montreal General Hospital, Associate Professor of Surgery, McGill University, Philadelphia: Lea and Febiger. 1929.

BLOOD LIPOIDS IN THE PSYCHOSES.

Dr. SVEN STENBERG of the Psychiatric Clinic, Konradsberg Hospital, Stockholm, has published an interesting investigation on the quantitative variations of total cholesterin and total fatty acids in the blood of cases of manic-depressive insanity and dementia praecox.[2] In his preliminary review of the literature on this subject Dr. Stenberg explains the widely varying conclusions of previous authors as due mainly to their failure to ascertain definitely the limits of variation of these substances in the blood of normal individuals. Data in reference to the normal percentage of total cholesterin and fatty acids in the blood being scarce, the author has carried out a series of such investigations in order to determine this. He finds the normal extent of this variation to be relatively great, and his investigations likewise shew that the blood lipoids, although they vary considerably from individual to individual, keep constant in the individual person. This is in agreement with the findings of the majority of previous workers. He has also taken into consideration the various physiological states (age, diet, hunger, menstruation, etc.) which are deemed to have an influence on the lipoid percentage. The author has, in addition, ascertained the exact limits of the experimental error in the methods which he has made use of. The method of estimation adopted by him was Bang's micromethod as modified by Blix, this being, in the author's opinion, the only micro-method in existence that has been thoroughly tested. In the manic-depressive group of cases the total cholesterin was found to be greater than in normal persons, and also greater during remissions. In the dementia praecox group the early stages showed the total cholesterin to be higher than in the normal and remittent cases; whilst the cases of over a year's duration showed not only no increase, but were characterized by a range of variability considerably greater than normal. The similar changes of the cholesterin in the blood in manic-depressive cases and in early cases of dementia praecox pointed to the possibility of some common clinical factor, the supposition being that some change in the emotional sphere might be the psychical factor corresponding to the blood changes. Proceeding on that assumption, Dr. Stenberg analysed the older cases of dementia praecox. Those cases with a heightened emotional tone showed an increased cholesterin content, whilst the emotionally dulled cases showed a low cholesterin content. Dr. Stenberg considers that this relationship between cholesterin content and emotional tone does not merely apply to the two groups of psychoses investigated, but that there is every reason to believe that it is a general phenomenon. He suggests as future lines of research the ascertainment of similar correlations between the lipoid content of the blood and the emotional tone in other groups of mental disease, and the effect of insulin both on blood lipoids and on the emotional state.

CARDIO-VASCULAR TUBERCULOSIS.

PROFESSOR PIC and Dr. MORENAS have divided their book Cardio-vascular Tuberculosis[3] into three parts—the tuberculous heart, the heart in tuberculosis, and tuberculosis of the veins and arteries. It is a work of academic rather than practical interest. In a leaflet introducing the book the publishers remark that, to get a comprehensive knowledge of this subject, a laborious search in medical literature is necessary. The authors have certainly undertaken this task for us; for so small a book the bibliography is immense.

With the exception of tuberculous pericarditis, tuberculosis of the heart is a clinical rarity. It practically never occurs as a primary condition, and is usually demonstrated in the post-mortem room as one of the features of the later stages of fatal tuberculosis of some other part of the body. Tuberculous pericarditis, though rare, is perhaps more common than is generally suspected, and deserves a more detailed and a more personal handling

than the authors have given it. It is to this section of the book that the average reader would turn for expert practical instruction, but he will find little more than the ordinary textbook of general medicine supplies. Tuberculosis of the blood vessels is a clinical curiosity—it is treated as such; the review of the French literature on the subject is interesting. That part of the book which deals with the heart in tuberculosis suggests that the authors know considerably more about cardio-vascular conditions than they do about tuberculosis.

TWO BOOKS ON AFRICA.

FOR thirty years Mr. CHARLES W. HOBLEY has had experience of exploration and administration in British East Africa. In his book *Kenya, from Chartered Company to Crown Colony*,[1] he relates these experiences. The colony has been described as "the heterogeneous collection of the most difficult Europeans, the most difficult Indians, and the most difficult natives in the British Empire." For this reason there is much that is interesting in Mr. Hobley's chapter on European colonization. He raises the question whether equatorial Africa can ever be suitable for permanent settlement by the European race, and, if not, what is the goal towards which British administration of the country is tending. So far as the coastal zone of equatorial Africa is concerned, he has no hesitation in saying that permanent settlement for Europeans is impossible, even if the mosquito could be abolished. The tropical sun is exhausting; the sultry nights impair rest; anaemia is common; and at certain seasons many people suffer from boils. Moreover, European children wilt and lose their energy. It is unlikely, therefore, that a permanent white colony will grow up in that zone. In the uplands of the interior, on the other hand, several thousand Europeans have established themselves, mostly during the last ten years. Opinions differ as to whether their settlement can become permanent. It has been held by some observers that Europeans, even in the highlands of tropical Africa, degenerate bodily, mentally, and even morally with long residence; and this degeneration has been attributed in part to paucity of certain mineral constituents in the soil. But Mr. Hobley questions whether the calcium or phosphorus content of a cabbage or a sheep varies in different parts of the world. He reminds his readers of the capacity of the human organism to adjust itself to changed conditions, such as increase of temperature, and points out that even if more carbonaceous matter is retained in the blood owing to lessened respiration, medical evidence is by no means agreed on the results. Nor is it safe to assert that anaemia results from excess of ultra-violet rays, since it is difficult to exclude the effects of concomitant protozoal disease. Mr. Hobley has no doubt, however, that the hot, dry, and windy spell of weather in Kenya which precedes the April rains is most trying to the nervous system of Europeans. He describes the measures he adopted to prevent exposure of the eyes and skin to the rays of the sun. Also he is convinced that one important cause of the deterioration of the health of Europeans in the tropics is bad cooking. His conclusion on the whole question is that, while the wastage of life in the first few generations of Europeans will be high, those who survive will adjust themselves to abnormal conditions of light, heat, and altitude, and will transmit to their descendants in greater proportion the characters which make for survival.

The question of the possibility of raising the African native to the status of a self-respecting free citizen is the underlying motive of M. RAOUL ALLIER'S book *The Mind of the Savage*.[2] M. Allier has worked in Africa as a French Protestant missionary. He has come to the conclusion that the modern African savage is a debased creature, who owes his arrested development to an all-pervading belief in magic. But even the most debased peoples, he says, have some ideal; and the unfortunate effect of the advent of ruling races is to shatter the moral edifice by destroying the political and social institutions of the native. Like Mr. Hobley, M. Allier does not despair of the situation, though he naturally attaches more importance to Christian mission work than to the preservation of as much of savage social institutions as is compatible with ordered government. His book is unnecessarily lengthy and discursive, but it contains many interesting observations on magic.

AIDS TO DERMATOLOGY.

WE welcome as a recruit to the ranks of the well-known series of "Aids" designed for students in their efforts to surmount examination difficulties, a slim volume *Aids to Dermatology*,[3] by R. M. B. MACKENNA, a name with a good dermatological tradition behind it; and we may say at once that, in its comparatively modest way, the volume and the author both prove themselves worthy of their parentage. In "tabloid" form it gives clearly and well the main facts and principles of dermatology, and the pruning and elimination of superfluous matter necessary to reduce the subject (including that of venereal disease) to 230 small pages has not interfered with the lucidity of expression essential to a student's manual. The publication of this little work—we believe the first cram book on the subject—raises the interesting question of the proper position of dermatology in medical education. There is no doubt of its importance to the practitioner, who often admits it and simultaneously confesses his own inability to make much headway with it, and commonly puts the blame on the sesquipedalian tendency of dermatological nomenclature. Probably the real reason why so many medical men find dermatology difficult lies in the fact that clearly cut differences are so often impossible to establish between various dermatoses, and there is a vagueness about it which makes the subject very difficult to teach unless the student is prepared to spend a larger proportion of his time thereon than is customary and than he can usually afford. The difficulties of dermatological nomenclature have very little to do with it, for the long names are mostly restricted to conditions seldom seen and therefore of little importance to the average student or practitioner. The teaching of dermatology to undergraduates is best confined to instructing them how to recognize and treat a few well-defined common conditions. A student who is able to achieve this much will be able to answer any question on skin diseases likely to be set in a qualifying examination, and will be able to manage successfully the bulk of his cases, even though there will remain a vast number of rarities beyond his ken. In short, dermatology is a vast subject to comprehend, but a small one to practise. For those whose requirements are modest and practical the little volume before us may be recommended. It gives sound information and advice in a convenient form.

DISEASES OF THE MOUTH.

MR. STERLING V. MEAD has had the pleasure of seeing a third edition of his work on *Diseases of the Mouth*[4] called for within ten months of the publication of the first. In his preface he ascribes it "not to the unusual value of the book, but to the unusual interest of the subject"; perhaps the fact that the book is so largely a record of personal observation, and that it is written in an attractive, terse style, may be another not inconsiderable factor. In the course of thirty-four chapters the author covers a wide range of subjects, describing on the one hand such dental conditions as will be helpful to the general medical practitioner, and on the other the conditions of "general" diseases which the dentist may be confronted with in the mouth. The author's experience of pulpless teeth is that "one cannot be too sure of a diagnosis." He finds that pulpless teeth do not remain constant, but that the condition may change, and therefore advises periodic examination of them. His

[3] *Aids to Dermatology and Venereal Disease.* By Robert M. B. MacKenna, M.B., B.Ch., M.R.C.P. London: Baillière, Tindall and Cox. 1929. (Fcap. 8vo, pp. viii + 236; 7 figures. 3s. 6d. net.)

[4] *Diseases of the Mouth.* By Sterling V. Mead, D.D.S. Third edition. London: H. Kimpton. 1928. (Sup. roy. 8vo, pp. 727; 336 figures, 43 plates. 42s. net.)

opinion of the dental granuloma is that, "whether it occurs in persons of low resistance, as claimed by some, or in those of high resistance, as claimed by others, it is a circumscribed, slow-growing area of infection which causes systemic disturbances and heals more slowly after removal and causes more exacerbation than the other types." The book suffers in places from brevity overdone—for instance (p. 133), what are the anomalies in form, size, number, etc., of the teeth due to rickets and other diseases of childhood? —and again, from a certain looseness of pathology, as when (Fig. 40, p. 110) caries of the distal surface of a molar is ascribed to "irritation from impacted third molar." Withal, it is a book well worth the attention both of the dentist and of the medical practitioner, and we think the author is justified in his hope that dentists and physicians will find in it the fundamental principles and practical knowledge necessary for their routine work in the mouth.

NOTES ON BOOKS.

DR. LUDWIG ENGLERT's work on Galen's treatise entitled Thrasybulos,[1] which is the latest addition to the series of studies on the history of medicine edited by Professor Karl Sudhoff and Henry E. Sigerist of Leipzig, is divided into two main parts. The first deals with the conception and classification of medicine in classical antiquity, from the pre-Hippocratic era down to the Hellenistic period. The second part, which forms the bulk of the work, is devoted to Thrasybulos, and is subdivided into sections dealing respectively with its subject and construction, Galen's relation to the gymnasts, with an account of their theory and practice, and lastly the special terminology of the treatise. The treatise derives its name from a probably fictitious personage named Thrasybulos, who had asked Galen's authoritative opinion as to whether the preservation of health belonged to the domain of medicine or to that of gymnastics. It is hardly necessary to add that Galen, after a prolonged discussion, comes to the conclusion that medicine is the predominant art, of which the preservation of health and gymnastics are subordinate departments.

In *Dental Anatomy*[2] Mr. M. DIAMOND incorporates the results of his studies of thousands of individual teeth, undertaken with the object of arriving at a basic, or as he calls it a symmetrical, form for each of the thirty-two permanent teeth. The larger part of the book is taken up by a detailed description of each tooth, followed by a technique for reproducing symmetrical tooth forms. Exact measurements of each "symmetrical" form are given, and the technique of reproducing them in wax is described. The guiding motif is the functional value of exact reproduction of any lost part of a tooth crown. Chapters are included on the bones, vessels, nerves, and soft parts of the mouth. The work will make a strong appeal to all interested in dental anatomy.

Dr. H. S. DICKEY is an American of nomadic instincts and a long memory. He appears to have wandered for more than twenty-five years, precariously picking up a living by practising medicine in Colombia, Ecuador, Peru, and Brazil. He has embodied his experiences in a book, *The Misadventures of a Tropical Medico*,[3] with the help of Mr. HAWTHORNE DANIEL, who has provided, perhaps, the literary setting for random reminiscences. The result is a very circumstantial account of the author's exploits as a captain (unpaid) in the Colombian Federal Army, of service in Putumayo with the Peruvian Amazon Rubber Company, of visits to the villages of head-hunting Indians, and of journeys through dense jungles and down immense, and almost unknown, rivers. He describes his relationships with Roger Casement, who was then employed by the British Foreign Office, and was instrumental in exposing the atrocities of the Putumayo Rubber Company, some of which the author had himself witnessed. He describes the process by which the head-hunters reduce the heads of their victims to the size of a fist, and how he received the reduced head of one Anguashi as a fee for curing a Jivero chieftain suffering from a snake-bite. Dr. Dickey's reminiscences will hardly rank with Bates on the Amazons as an authoritative description of a country that is still unfamiliar; but they make a readable story; and as Dr. Dickey now proposes to turn himself into an explorer pure and simple, and to search for the source of the Orinoco River—the only great river in the world, he says, the source of which is still unknown, he may yet produce some solid pioneering work. At the end of his book he gives his fellow countrymen in the United States a dressing-down for their ignorance and lack of discretion in their treatment of South America.

PREPARATIONS AND APPLIANCES.

A MODIFIED BOYLE GAS AND OXYGEN APPARATUS.

DR. A. H. MACKLIN (Dundee) writes: I have devised a modification of the Boyle gas and oxygen apparatus; it enables the lungs to be instantly distended with pure oxygen, or, if preferred, with oxygen containing a small percentage of carbon dioxide. Some such arrangement is necessary in any standard machine used for the administration of gas and oxygen pure. No apparatus made in this country that I know of is so fitted, and I have never been able to regard the generally used Boyle apparatus as a satisfactory instrument for giving gas and oxygen to all kinds of cases without the addition of some further anaesthetic, such as ether or chloroform. With one of the more complicated American machines, such as the McKesson model, pure gas and oxygen can be used as a routine, but the price renders their general use prohibitive under ordinary conditions in this country. To obtain full relaxation with gas and oxygen it is nearly always necessary at some stage of the operation to give a saturation of nitrous oxide, which causes marked cyanosis; no anaesthetist can feel comfortable with a "blue" patient unless some arrangement exists for instantly shutting off the gas and delivering oxygen under pressure (with or without CO_2) direct to the lungs, especially if ether and/or chloroform are being used in addition.

ROSS MACKENZIE of Aberdeen modified the standard Boyle apparatus by the addition of a perforated measuring tube in the mixing chamber for CO_2. I have added a further modification in which by the quarter turn of a tap the nitrous oxide is instantly shut off; by the same movement the oxygen and carbon dioxide (if used) are diverted from the inlet to the outlet side of the apparatus and delivered direct to the face-piece of the inhaler. This is attained by the addition of three small parts: (1) a special by-pass soldered on to the inlet tubes, (2) a valve to prevent back pressure through the apparatus; and (3) a stopcock on the inhaler, which shuts off the thin-walled rubber bag. The gases are conducted through tubing from the cylinders to the three inlet tubes of a triple tap, which ordinarily directs them downwards into the mixing chamber and thence through the apparatus in the ordinary way. By a quarter turn of a small lever they are diverted upwards to two outlets corresponding to the oxygen and carbon dioxide inlets respectively. There is no outlet for the nitrous oxide in this position, and it is thus automatically shut off. The oxygen and carbon dioxide outlets are joined, and the gases are carried along a tube placed above the apparatus (with just sufficient clearance to avoid the chloroform and ether by-pass levers) to enter the second additional part; this is screwed on to the outlet and fitted with a valve to prevent back pressure into the ether and chloroform containers should they happen to be open. The mixed oxygen and carbon dioxide are conducted from the apparatus along the usual delivery tube to the inhaler. The inhaler usually supplied with the standard Boyle apparatus, in which the delivery tube enters directly into a thin-walled rubber bag, does not allow of sufficient pressure reaching the face-piece, so I use a Geoffrey Marshall inhaler in which the gases are delivered into the metal portion between bag and valves. The third additional part, a stopcock, is situated between the delivery tube and the thin-walled bag, which it shuts off. With the valve lever at "no valves" the diverted gases are delivered to the face-piece at the same pressure as they leave the cylinders, and this can be altered as required at the fine adjustment valves on the cylinder heads.

The whole of the additional parts do not add much to the cost of the original Boyle apparatus, and should greatly enlarge its already very wide range of usefulness. A manometer and a simple safety valve fixed at the outlet end of the apparatus make it safe for intratracheal work. For conducting the nitrous oxide from the cylinder I use pressure tubing of medium weight, and connect it to the tap by means of a Shelley patent fastener (commonly used for motor tyre pumps).

One disadvantage of the Boyle apparatus for some anaesthetists is that it has a left-hand delivery, and, as a further modification, I prefer the measuring chamber to be situated at the right-hand side of the apparatus. Messrs. Down Bros. are making the parts.

PROGYNON.

"Progynon," made by Messrs. Schering Ltd., is a preparation of the female cyclical hormone. It is standardized on the lines of the Allen and Doisy method to contain 250 mouse units per dose. The preparation is intended for oral administration, and the makers claim that animal experiments and clinical tests have shown that it is active when administered orally. They recommend administration of about 5,000 units a month. The literature quoted by the makers records successful treatment of climacteric disturbances, defective menstruation, etc.

THE SUN CURE AND THE WORK CURE IN SURGICAL TUBERCULOSIS.

BY

AUGUSTE ROLLIER, M.D.,

SURGEON-DIRECTOR OF THE HELIOTHERAPEUTIC ESTABLISHMENTS, LEYSIN; HONORARY PROFESSOR IN THE UNIVERSITY OF LAUSANNE.

HELIOTHERAPY has come to be associated especially with high altitudes in the Swiss Alps. More than a quarter of a century ago the first clinic for the treatment of surgical tuberculosis by general and systematized heliotherapy was opened by me at Leysin, and the results have proved so favourable that heliotherapy has become recognized as the treatment *par excellence* for surgical tuberculosis. Leysin is situated in Switzerland, overlooking the upper Rhône valley and facing the picturesque ridge of the Dent du Midi and neighbouring snow-capped peaks. Although its height is between 4,000 and 5,000 feet, the site is protected from the north winds by pine-clad uplands and it slopes steeply towards the southern sun. The air is therefore still, and the daily amount of sunshine is exceptionally great, both in winter and in summer, so that heliotherapy can be practised here all the year round.

The idea of a work cure for bed-ridden patients is of more recent introduction, and might at first sight appear to be a contradiction in terms. Occupational therapy has for long been applied to consumptive patients—for example, by George Bodington (1840)—and in more recent times by Dr. Marcus Paterson, who, at Frimley, prescribed graduated work in the form of gardening, Dr. Varrier-Jones at Papworth, as well as by Sir Robert Philip, Sir Robert Jones, and many other authorities both in England and *in America*.

Rationale of Heliotherapy.

It would be well, in the first place, to say *something* in regard to the sun cure as practised by us for cases of surgical tuberculosis. For *many years it was believed that* the external lesions produced by the bacillus of Koch constituted a simple local malady, *which was capable of cure* by purely local treatment, and there resulted an era of surgical intervention, which only too frequently opened the door to secondary infections more serious than the tuberculosis itself. With surgical treatment in the past has been associated complete immobilization in closed plaster casts, which is too often respected as an unassailable doctrine. Such heavy and completely rigid apparatus possesses the grave disadvantage of atrophying the integuments, muscles, and skeleton, of favouring ankylosis of the joints, and, as a result of this excessive fixation and prolonged inactivity, of producing in the patient physical and moral torpor, which gradually breaks down the natural defences of his organism.

Professors Bonnet and Poncet at Lyons were the first to oppose operative intervention and to advocate the application of the sun's rays to localized centres of surgical tuberculosis. Dr. Bernard of Samaden in 1902 was the first in Switzerland to apply heliotherapy to the treatment of wounds, and later to external tuberculosis, but this insolation was localized to the part affected. In the early years of my practice at Leysin, I became convinced of the importance of general exposure to the sun's rays in addition to exposure of the part affected, and in 1903 I opened my first clinic for the treatment of surgical tuberculosis by general and systematized heliotherapy in Le Chalet at Leysin. We now have some one thousand of such cases constantly under treatment in numerous clinics.

The practice of this general and systematic heliotherapy led us quite logically to the suppression, first, of almost all surgical intervention, and then of every form of closed plaster cast, replacing these with simple orthopaedic splints which always allowed the sun's rays to have free access to the whole surface of the integuments. Carried out in this way heliotherapy soon demonstrated its efficacy. Sun bathing is, on the one hand, the finest stimulus of exchange and of vitality of the organism, and is therefore the best regenerator of the "soil"; on the other hand, it is the rational treatment of the tuberculous centres by reason of the sedative, bactericidal, cicatrizing, and recalcifying action of the solar radiations. One may confidently affirm that there is not an organ in the human body which escapes the power of the sun's life-giving rays. Judiciously applied, the air and sun bath stimulates the appetite and the digestive functions, and renews energy. Under its influence, especially at a high altitude, the number of red corpuscles and the haemoglobin content of the blood are increased, and the exchanges become more active.

The skin, when put back into its normal surroundings—that is to say, when it is placed in progressive and continuous contact with air and sunshine—is toned up, becomes . . . . . ains its full physiological functions, circulation, innervation, absorption, elimination, immunization, and internal secretion. One of the most striking evidences of the sun's action is that without any help from massage or electric applications, one can watch the muscles of bed-ridden patients develop and harden in a harmonious and often athletic manner. This may be explained partly by an improvement in the *capillary circulation*, and possibly also as a result of the vibratory impact caused by the sun's rays on the network *of sensory nerve endings in the skin. Sunlight, in both* rickets and tuberculosis, has also an indisputably recalcifying *action on the bones. This cicatrizing and recalcifying action on centres of bacillary necrosis, however deeply* situated, is most evident in a collection of more than *50,000 radiograms which we possess. In many cases—for* example, where the head of the femur has almost disappeared—*the reconstitution of the bone is so complete that* one may, without exaggeration, term it "restitutio ad integrum."

Orthopaedic Arrangements.

A brief outline of the orthopaedic treatment adopted by us in association with the heliotherapy is as follows. The bed is very simple, provided with a special firm mattress upon a movable bed-frame, of which the position can be regulated at will. The bed can be wheeled readily from place to place as required, and is provided with a firm table at the head, which can be set at any angle and is capable of bearing an electric motor and tools.

In Pott's disease of the thoracic and lumbar regions we do not employ any support other than a wedge-shaped pillow, and we alternate the dorsal with the ventral position, in which the patient rests partly supported by his elbows, so that he can use the hands for working. The development of the dorsal muscles under full sunshine is remarkable, and they form a perfectly sufficient natural corset. In the case of cervical disease, the patient lies upon his back and an extension apparatus is attached to the head.

For hip disease we employ an extension apparatus attached to the thigh and a sliding splint, whilst the patient is raised upon a cushion placed beneath the pelvis, so that the vicious positions of the hip-joint are readily corrected, and the region of the hip is fully exposed to the sunlight. For osteo-arthritis of the knee we add to heliotherapy extension of the leg upon an inclined plane, so that compression of the articular surfaces is relieved and circulation is promoted. We attach great importance to these rational positions in treatment of the hip and knee. The ankle is, of all the joints, with the one exception of the wrist, the most favourable from the point of view of curability. Fixation is effected in a hollow splint, which permits free access of air and light to the leg and joint. Elevation upon an inclined plane, as in the case of the knee, is desirable.

In arthritis of the shoulder we seek to fix the arm in a position of abduction by means of an apparatus which is attached round the waist and can be opened gradually. The patient during treatment has full use of the forearm and hand. We have never been obliged to have recourse to resection of this joint, and the average duration of treatment has been about fourteen months. For the elbow we make use of a double hollow splint, by which the joint is kept in the rectangular position. In about half of our cases there has been complete restoration of *articular* function, while in the majority of the remainder the range of movement on recovery has varied *from 30 to 70 degrees.* Osteo-arthritis of the wrist is treated upon a splint with, in some cases, extension fixed to the *fingers, so that the* hand, wrist, and forearm in any case remain uncovered. In this position cure has, in *our experience*, invariably been accompanied by return of the function of the joints.

Osteo-arthritis of the metacarpus and phalanges is treated by fixation upon a small splint, accompanied by extension, and complete recovery is almost always the rule, provided secondary infection has not been present.

Tuberculosis of the pelvis, whatever be its localization —for example, as a sacro-iliac arthritis—has invariably recovered in a period of about one year under heliotherapy, when the disease was closed, even in cases with cold abscess; but cases that have become open, whether as the result of spontaneous rupture or of surgical intervention, have proved most refractory to treatment. The formation of a cold abscess is a quite natural phase of the healing process, and so far from its presence constituting a serious complication, in our opinion, it forms one of the attributes of healing. It may be regarded as a depot of antibodies, which contributes in great part to the immunization of the patient. We therefore deprecate its premature puncture.

The treatment of secondary infection necessitates a special technique. The first condition is to ensure effective drainage from the sinuses. We have recourse in certain cases to continuous siphonage with Dakin's solution, or physiological salt solution, and in other cases the patient is sent for a course of sulphur water baths, particularly of those at Lavey.

The action of heliotherapy upon sequestra is most interesting. In many cases of closed osteo-arthritis the sequestra gradually absorb, but more often, as shown by a series of radiograms, they become organized and incorporate themselves again with the living bony tissue. In general, we consider it useless and mistaken to interfere too quickly with a sequestrum, unless this is "en panne" or "en grelot." In closed tuberculosis the sequestrum is rarely necrosed, and consequently it is able to reorganize easily with the bony lesion from which it is temporarily detached. In open tuberculosis the sequestrum is practically always necrosed, as in osteomyelitis, and it consequently eliminates itself, or should be eliminated by sequestrectomy.

One of the few forms of tuberculosis in which we incline to early surgical intervention is renal tuberculosis, when operation is advisedly associated with heliotherapy.

Work as an Adjuvant to Heliotherapy.

The effect of heliotherapy on the mentality of the patients is too apparent and too striking not to deserve special mention. Many patients, after a course of sun cure, in proportion as they have improved physically, have improved morally, and hope has revived. The beneficent light of the sun, in winter as in summer, brings a deep and intimate sense of well-being. Even in the mountains, however, there are days when the sun does not shine, and even the most continuous sunshine is not always enough to re-store the morale of unfortunate patients, haunted by the insoluble problem caused by the loss of their occupation and by the painful knowledge that their homes must be a burden and expense to others.

To raise the morale of these invalids, whose trouble is mental as well as physical, and to bring them pecuniary assistance, we have instituted the work cure, which can be carried out in all weathers, in open-air balconies when the sun shines, and in neighbouring workrooms when the weather is unfavourable. Experience has convinced us that invalids, put under the discipline of work appropriate to their individual needs, soon become aware of a steady return of their powers, and experience that encouraging sensation which accompanies the normal functioning of their organs, and the adaptation of the human machine to work. The marvellous moral and physical stimulus of manual labour may be realized by watching the joyous animation which reigns on one of our balconies, the inward satisfaction to be read on those bronzed faces. Special contrivances make it possible for the patients to work in all the positions which their treatment necessitates, without ever endangering the latter.

Our first attempt at organizing the "work cure" was made in 1909, when we started a work colony at Leysin, which provided the necessitous patients with easy tasks, such as basket-work, caning of chairs and other furniture, woodwork, etc. Thanks to the salary they obtained from it, the inmates of the colony could, to a large extent, help to pay for their maintenance, and they lost the depressing sense of uselessness, and established contact with normal life again as they finished their cure. The results were excellent, and in the following year we established a small agricultural colony for children at Cergnat, near Leysin. Here the work included the rearing of cattle, milk production, market gardening, and bee-keeping, the inmates being recruited from among young convalescents who had suffered from surgical tuberculosis, and also from among delicate children sent to us direct from the plains. Later on, to this agricultural colony we added the "school in the sun," where predisposed children could have the necessary physical training, this being the first solar *préventive* institute at high altitude. The children of our clinics, whether confined to bed or not, receive open-air instruction in school tasks, varied by light manual work; this breaks the monotony of treatment, gives an object to long hours of idleness, and introduces healthy emulation among the children.

During the war much experience was gained at the Swiss military clinic in Leysin, which we had been called upon to organize in 1915 for cases of "surgical" tuberculosis. Here the invalid soldiers devoted themselves more especially to the making of slippers and toys, but the work cure expanded to the manufacture of more than eighty different kinds of articles, and an annexe was built for convalescents, where large workshops enabled them to work at their ease in spacious sun balconies, or indoors if the weather was bad. The excellent results of this work cure encouraged us to introduce it more and more widely in our various clinics, until it became no longer a matter of fitting up makeshift workshops in our popular clinics, but of building a special establishment, where the work could be organized, and, like heliotherapy itself, included in the patients' regime in such a way that their orthopaedic and solar treatment would in no way be interrupted.

For this reason we have built an international factory clinic with 120 beds, where indigent patients, suffering from surgical tuberculosis, will benefit, from the moment of admission, by a model technical organization, and where they will have an opportunity of earning their livelihood by easy and remunerative work, while continuing their solar treatment. This establishment will have the dual character of a factory and a clinic. The spacious balconies and dormitories will be fitted up as workshops, fully exposed to air and sun, and the patients will have at their disposal, either upon a table attached to each bed, or near their beds, very complete and specially adapted appliances worked by electricity in such a way that the work will never interfere harmfully with their solar and orthopaedic treatment. Bed-ridden patients will make pieces of small mechanism, such as parts of watches, hosiery, pottery, etc., to the order of factories and workshops that have already promised us substantial and regular orders. Work demanding more effort will be reserved for convalescents who will work in special rooms on the ground floor of the factory.

A whole floor will be devoted to an international school of commerce, where young patients can obtain an official diploma, and there will be courses of modern languages. Finally, the highest story of the building and the solarium (a flat roof constantly exposed to the full effect of air and sun) will be reserved for experimental observations upon the physiological effects of work carried out under exposure to full sunshine. Here, in a suite of laboratories some 4,500 feet above sea-level, the chemical and physiological equipment necessary for research upon respiration, excretion, metabolism, fatigue, and other factors allied to working capacity, will be provided.

If sufficient funds are received for the complete realization of this project, the sum chargeable to working-class patients will cover merely their maintenance and the cost of working materials, so that it will be possible for the patients, while under treatment, to support their families at home. If this hope is realized, the factory clinic will be a useful contribution to the difficult social problem of disposal in cases of surgical tuberculosis among the indigent, who, being thus provided with means of support, will be as advantageously placed for treatment as members of the privileged classes. The building is now almost finished, and it is anticipated that it will be fully equipped and opened for the reception of patients at Easter, 1930.

British Medical Journal.

SATURDAY, DECEMBER 28TH, 1929.

THE STUDY OF PAEDIATRICS.

WE publish to-day at page 1185 an address upon the study and teaching of paediatrics, by Dr. Leonard Findlay, professor of paediatrics in the University of Glasgow, delivered in remote Belgrade, but dealing in plain English with what he considers to be a fundamental fault in our system of medical education in this country—the neglect of paediatric studies. That Professor Findlay's complaint has much justification few, we think, will deny. In this country this great branch of medicine—of the highest educative value to the student, and of supreme importance to the State—does not occupy the high place that it holds unquestioned in the medical schools on the Continent and in America.

The provision made for the study and teaching of paediatrics in many of our medical schools is quite inadequate. To set aside an infants' ward and to appoint a visiting paediatrician is not to constitute a department of paediatrics. To admit a certain neglect of this great subject is in no way to imply that there is any want of capacity in the small but growing number of physicians who have devoted themselves to the study and care of the child. In no country is the clinical material better investigated or more successfully dealt with. Perhaps no children's hospital in the world has a greater reputation for accurate clinical teaching and investigation than the Hospital for Sick Children, Great Ormond Street, yet we do not think that Professor Findlay would regard either Great Ormond Street or any other hospital in London as offering us a paediatric department in the sense in which he uses the term. In Glasgow, it is true, Professor Findlay himself presides over an admirably equipped department, and may therefore speak with peculiar authority. In one or two other places, by great personal efforts, a paediatrician has succeeded in surrounding himself with the essentials of a satisfactory department, but in general too little has been done to remedy the state of affairs which Professor Findlay deplores, a state of affairs admitted by many, even among ourselves, to be unsatisfactory, and a constant source of wonder to visiting paediatricians from abroad.

Professor Findlay glances at one aspect of the question which is perhaps the direct result of this relative neglect of paediatric studies. He speaks bluntly of pseudo-specialists in this subject. While many of our infant welfare centres are admirably conducted, it is, we think, true that this is not always the case. Training in paediatrics must necessarily be long and arduous. We can conceive that the head of an orthopaedic department might well regard his assistant after one or two years of intensive study as well qualified to undertake a very large part of the routine work in that department, but after so short a period of study the assistant in the paediatric department would have taken but a few uncertain steps on the long course that is necessary before his opinion could be of first-rate value. Yet in paediatrics, and especially in those branches of it which deal with the slightest departure from health, there is, as Professor Findlay implies, nothing to prevent anyone, though lacking in the necessary training and experience, from assuming the role of an expert in the work. In most specialties, properly so called, the necessity of becoming familiar with the use of diagnostic instruments of precision, and of acquiring an obvious dexterity, of itself implies that a certain apprenticeship has been served.

We conceive that Professor Findlay's problem is not so much how to convince universities and medical schools of the need for paying greater attention to the study of disease in childhood, as to devise means of overcoming the difficulties that surround all attempts to make changes in our too complicated arrangements for medical education. Paediatricians in this country are few in number, and in consequence comparatively uninfluential. Some years ago their combined protest, supported actively by the Ministry of Health, was a factor in inducing the General Medical Council to recommend that all students presenting themselves for the final examination should be required to produce evidence of three months' attendance upon instruction in diseases of children. Without any special examination in the subject such a regulation can of itself effect little improvement. Most students must perforce address themselves to the subjects on which they will be searchingly examined, and if no paediatrician examines in his subject paediatric studies will suffer a corresponding neglect. The teachers of obstetrics and gynaecology have recently asserted themselves in no uncertain manner in order to secure an adequate recognition of their own subject. Behind their demand, because of their numbers and their influence, was a force that was almost immediately successful in overcoming the obstacles they found in their path. Teachers of paediatrics can of themselves exercise no such powerful influence. The dearth of professorships of paediatrics in this country is both significant of the neglect of which Professor Findlay complains, and at the same time contributes to it. If the study of the child and his disorders is to take its place, beside general medicine and the diseases of women with midwifery, as a subject of major importance in the curriculum of our medical schools, it must be because its right to do so is conceded by all; because teachers of surgery, ophthalmology, and oto-rhino-laryngology, of diseases of the nervous system and of diseases of the skin, recognize that, great as is the importance to the community of a knowledge of their own specialties, the knowledge of the child and its disorders is more important still.

COMPLICATIONS OF OPERATIONS FOR PILES.

THE discussion on the complications of operations for piles, opened by the president, Mr. Cecil Rowntree, in the Subsection of Proctology at the Royal Society of Medicine, on December 11th, was chiefly marked by fundamental differences of opinion, not only about the frequency of complications, but also about their causation and treatment. As the president remarked in his opening address, these operations are done so often and under such varied conditions that complications might be expected to be common, and the fact that they are not furnishes an excellent testimonial to the skill and care with which they are generally performed. The easier and the safer an operation the greater is the discredit if anything goes wrong, for, after all, it must be remembered that it is by the success of every-day surgery that surgery and the surgeon are judged. There can be no question, therefore, of the value of discussion of the minor details of what many will regard as a minor operation. Many complications

were referred to, some of them quite familiar, others very rare, ranging in severity from such minor troubles as an abnormal degree of post-operative pain to serious disasters such as ulcerative proctitis, or even death from pylephlebitis. Fortunately the latter is so exceptional as hardly to enter into the ordinary field of probabilities, and, as one speaker said, it is to be supposed that the average surgeon only thinks of its possibility in a whisper, if at all.

The progress of the discussion made it clear that with regard to operative method some form of ligature technique holds the field against all others. Whitehead's operation was definitely condemned as unnecessary, unsurgical, and more than likely to be followed by difficult and troublesome complications. It was agreed that the clamp and cautery has much to recommend it in the direction of freedom from after-pain and absence of stricture formation, but the disadvantages of a method which is applicable only to selected cases, and carries with it such unpleasant olfactory accompaniments, outweigh most claims that may be made for it. The ligature operation, which is probably the type chosen by 90 per cent. or more of experienced surgeons, has almost everything in its favour. First, the pile and only the pile need be removed by it; secondly, the quantity of blood lost is minimal; thirdly, the ligature, when properly applied, does appear to preclude the possibility of haemorrhage with complete certainty; and finally, the time required for the completion of the operation is but a few minutes. This operation, in its original form, consists in the ligature of the pile low down in the anal canal; the only dissection that is necessary is the removal of redundant skin and the separation of the muco-cutaneous border of the pile from the underlying tissues to provide a groove in which the ligature lies, and in order to avoid the inclusion of the highly sensitive nerve endings of the anal margin in the loop of the ligature. This is the operation described by Salmon so many years ago.

In recent years the ligature operation has, in the hands of many surgeons, undergone a vital modification. This consists in stripping up the pile from the underlying tissues with the object of making a convenient pedicle, as it were, which is then transfixed and ligatured at a higher level than in the older type of operation. Although at first sight this would appear to be an improvement upon the earlier method, it has to be remembered that the stripping up of the pile must inevitably leave an exposed area, or several exposed areas, of submucous tissue which can only heal by granulation. It is an open question how far this denudation is responsible for some of the more unpleasant complications of piles round which discussion nearly always centres; it is fairly evident that even an experienced surgeon operating under the best conditions must leave a raw area several centimetres square which has to heal as best it can. We know that it generally does heal extremely well, but we also know that in a certain proportion of cases (which some observers put as high as 5 per cent.) there is a degree of contraction of such severity as to demand treatment for its relief. Of course, it does not often happen that the contraction is permanent and that a stricture results; but when it does, as Mr. Rowntree remarked, the patient who has a stricture substituted for his piles is not likely to forget either the bad bargain he has made or the surgeon who effected the exchange.

Much has been made of the possibility and the desirability of effecting aseptic conditions for rectal operations, and no doubt with scrupulous care a high degree of asepsis may be obtained in the anal canal for a period of time which can hardly be reckoned in more than minutes. Were it possible to maintain complete asepsis throughout the process of healing it is likely that any and every type of operation for haemorrhoids could be performed with complete immunity from such complications as haemorrhage, proctitis, anal abscess, stricture, and so on. But, the bacteriological flora of the rectum flourishing as it does, we cannot feel surprised that the outcome of the discussion was a pretty generally expressed opinion in favour of a simple ligature operation and as little interference as possible with the rectal mucosa.

HELIOTHERAPY AND WORK IN SURGICAL TUBERCULOSIS.

NEARLY a century has passed since Professor James Syme, in 1831, published his *Treatise on the Excision of Diseased Joints*. In the latter part of the nineteenth century this was regarded as one of the greatest additions that had ever been made to conservative surgery. Since that time, however, methods of treatment have improved and standards of recovery are higher, so that the outlook of surgery and medicine, as well as of the general public, upon this subject has greatly changed in the direction of still further conservatism. On September 21st we published several important articles dealing with the operative treatment of tuberculosis of the joints, and in our present issue (p. 1206) appears a paper by Dr. A. Rollier of Leysin, who has devoted himself to treating surgical tuberculosis by orthopaedic appliances and heliotherapy for over twenty-five years, during which time he has had an immense experience. His most recent enterprise is the outcome of a consideration he has given for some fifteen years to the part that might be played by occupational therapy as an adjunct to his other methods of treatment. The robustness of insolated patients and their relative freedom of movement, rendered possible by the type of orthopaedic apparatus employed at the Leysin clime, inevitably suggested that work and activity might be used for the further betterment of their local and general condition. There can be no question of the great psychic value of mental and manual occupation in distracting the patient's attention from his condition, especially when he is in poor circumstances and accustomed to working with his hands. Further, under a system of treatment which discards rigid immobilization and aims at the constant maintenance of as much movement as can be effected without causing pain, the measure of activity thus attained in patients confined to bed has an important local effect upon the diseased part. The factory Dr. Rollier has now established at Leysin, in which patients confined to bed by spinal or hip disease can carry out productive manual labour, is an important experiment, not merely in surgical practice, but still more in social medicine. It is expected that the factory, with accommodation for 120 bed-ridden operatives, will be opened early in the New Year, and both the medical profession and all those occupied with labour conditions will watch its progress with the greatest interest. Donations to the fund for building and equipment may be sent to the Comptoir d'Escompte de Genève, Leysin, Switzerland.

EPSOM COLLEGE.

THE charitable activities associated with the Royal Medical Foundation of Epsom College depend much on the genero-ity of annual subscribers, and at this time of year, therefore, attention may well be directed to the excellent services that are being rendered by this institution to the medical profession; some details of these will be found in our advertisement columns this week. Pensions are provided for fifty medical practitioners or their widows who

are over the age of 60 and in urgent need of such assistance. Fifty sons of necessitous doctors enjoy foundation scholarships, entitling them to boarding, clothing, and education at the school. For these two purposes the sum of about £9,000 is required annually, and four years ago it was admitted that the high cost of living makes it very desirable for the pensions to be increased; such a step can only be taken, however, if more money is forthcoming from subscribers. Each guinea entitles the subscriber to ten votes for candidates for these pensions and scholarships, and assists the charity in its endeavour to provide a refuge for members of our profession or their dependants who have fallen on evil days. Smaller sums than a guinea, though they do not confer voting rights, are welcomed, inasmuch as they add to the amount of relief which can be given. Epsom College as an educational institution has won a high name in the scholastic world. The majority of its pupils are the sons of doctors, and for those who propose to follow their fathers' profession scholarships are available in the London medical schools. Progress is being made towards the urgently needed provision of a new sanatorium; of the £30,000 required £7,500 has now been collected. The opening of this building, with its isolation wing, will make room for forty more boarders in the present college buildings, and thus reduce somewhat the long waiting list of applicants for admission. We therefore commend the present appeal to the careful attention of readers of the *Journal*. Epsom College as a great educational centre for the sons of medical practitioners deserves wider recognition by members of our profession; as a charitable institution the Royal Medical Foundation should command the warm sympathy of all whose circumstances permit them to help their colleagues in distress.

CINEMATOGRAPHIC DEMONSTRATION OF LIVING TISSUE CELLS.

ON December 11th, Dr. R. G. Canti demonstrated before the University of London Medical Graduates Society three cinematographic films, whose preparation had formed part of an investigation on cancer carried out at the Strangeways Research Laboratory, Cambridge. A cinema technique applied to microscopy has not merely the advantage that it is less exhausting to the investigator than the method of direct visual observation, but it enables him to examine at leisure records obtained over a long period of time, and to re-examine them as often as he may find necessary for their interpretation. As, moreover, films may be run in a reverse direction it permits him to trace any changes that may have occurred through all the stages that led up to them. The first film showed the growth and multiplication of cells from the periosteum of chick embryo and from a mass of Jensen's rat sarcoma; the second some of the effects of irradiation on these cells; and the third the internal structure of the fibroblasts of the choroid of chick embryo, as shown up by the method of dark-ground illumination. In the different experiments photographs were taken at intervals of 3, 10, 30, and 60 seconds, but the resulting pictures were shown at the usual speed of sixteen a second. Varying with the rate at which the photographs were taken, therefore, a speeding-up effect was obtained of 50, 120, 480, or 960 times. On the first film cells could be seen spreading outward from the explant, the wandering cells forming, as it were, an advance guard, followed closely by the fibroblasts, and soon the whole field appeared to be covered with a jostling population of outward-moving cells. Cell division could be seen to occur in four stages: *prophase*, *metaphase*, *anaphase*, and *telophase*. The cell about to divide seemed to shrink, and the nucleus lost its outline, the chromosomes became visible, formed an equatorial belt, and moved rapidly to the poles, while from the surface of the cell bubbles of protoplasm were shot out with great rapidity, so that the whole cell seemed to be thrown into a state of violent agitation; finally the agitation subsided, a deepening constriction appeared in the protoplasm, the cell divided, and the two newly formed daughter cells wandered away from each other in opposite directions. The cells of Jensen's rat sarcoma are smaller than fibroblasts, and are provided with several long pseudopodia, having at their extremities delicate branching filamentous processes. These processes are actively phagocytic, and on the film they were seen to take up small fragments and pass them through the pseudopodium into the granular cytoplasm of the actively moving cell. Larger fibroblastic cells were also present and seen to be moving relatively slowly. Photographs of an older culture of Jensen's rat sarcoma showed the motile cells in process of degeneration. The cells were observed to shrink in size and become rounded in shape, and then to throw out continuously moving bubbles from their surface. Such degenerate cells, said Dr. Canti, had never been seen to return to the actively motile form. In the second film, which showed the selective action of radium emanation, the wandering cells of the periosteum of chick embryo were seen to be affected to a greater extent than the fibroblasts. Soon after irradiation was started cell division ceased to occur, and the cells, which till then had been in active movement, stopped still as though paralysed. As time went on they became spherical and their edges hazy and irregular. Still more marked was the effect of irradiation on the cells of Jensen's rat sarcoma. The actively dividing cells were immobilized with dramatic suddenness: they became rounded in shape, and started to break down. It was noteworthy that all the cells of the rat sarcoma, whether of the mobile or fibroblastic type, were equally affected by irradiation, and that the effect was produced in about the same time as it had been on the wandering cells of the normal tissue. The photographs afforded evidence, therefore, not only for the hypothesis that radium emanation has a selective action on malignant cells, but for the view that such selective action is exercised generally on cells undergoing rapid multiplication. In the third film various cell structures that had not been made visible by the method of direct illumination were shown up in clear outline. The whole cell stood up clearly from the background, its nucleus sharply defined, and the nucleoli readily distinguishable from the surrounding nucleoplasm. The cell granules appeared as bright bodies moving with greater or lesser rapidity, and the mitochondrium was seen as bright threads wriggling slowly about the cell with worm-like movements. Occasionally one of the mitochondria was seen to divide: the irregular curved thread would suddenly straighten itself out like a bar, and then, as it were, snap in two parts. At the conclusion of the demonstration Mr. McAdam Eccles, on behalf of the University of London Medical Graduates Society, expressed the gratitude of its members to Dr. Canti for giving them the opportunity of seeing the films, and their appreciation of the patience and the ingenuity that had been devoted to their preparation.

MEDICAL EDUCATION IN AMERICA.

THE third report of the influential American Commission on Medical Education dealt with general principles (*British Medical Journal*, January 26th, p. 161). In a supplement to the third report[1] a critical summary is given of some of the changes in procedure which have been put to a practical test in a number of the American schools of medicine, and serve thereby to illustrate certain of the general principles of training emphasized in the earlier report. The schools are referred to by letters of the alphabet, and not by their

[1] *Supplement to the Third Report of Commission on Medical Education, May, 1929.* New Haven, Conn. (Pamphlet, pp. 82.)

names, and without considerable knowledge of the local conditions it is therefore very difficult to identify them. The former period of two years' pre-medical work has now been extended to three or even four years in most of the better schools of medicine, which can easily fill their classes with college graduates; and as 95 per cent. of the graduates follow their medical course of four years by a hospital internship of one to two years, it takes about ten years from the date of entering college for the student to become financially independent. The cost of medical education is naturally going up, and the fees paid by students supply, as shown by the average of the figures from sixty-three schools, little more than one-third of the total, the difference being met by endowment and from other sources. In the sixty-three schools, 42 per cent. of the budget goes to provide salaries for the whole-time teachers, and 6 per cent. to part-time teachers. During the last few years the total amount of work, as shown by the number of hours required, has been somewhat reduced in the majority of schools; thus in thirteen schools which in 1925 demanded 4,000 or more hours, there has been an average reduction of over 400 hours, but there are wide variations; in twenty schools taken at random the hours required for anatomy varied from 1,267 to 480, for medicine 1,030 to 428, for surgery 660 to 332, and for gynaecology and obstetrics 368 to 168. Although much consideration has been given to uniformity and standardization, there is probably far more variation in the curriculums at different schools than is generally assumed. Three types are described. The first is the orthodox standardized curriculum of recent development, intended to familiarize the students, who all take the same courses, with every phase of medical knowledge; the amount of instruction is heavy, and the staff is small. The second type is represented by a small number of schools closely allied with universities, having few students, who have much more freedom, working on graduate rather than on undergraduate lines, and specializing early; the teaching staff is large, and there are full-time clinical instructors. The third group is intermediate between the other two, and offers a comprehensive training for all and special opportunities for a limited few. Teaching in pharmacology is becoming less concerned with pharmacy and more with the physiological action of drugs, thus forming a bridge between physiology and therapeutics. Clinical-pathological conferences, in which the physician in charge of the case first gives the clinical history and diagnosis, and the pathologist then shows the post-mortem conditions, are well established at some schools, as are joint demonstrations of surgical problems by surgeons and anatomists. Efforts are made to remove the reproach that the student does not know how to deal with the sick person; thus at one school 15 per cent. of the fourth-year students follow the daily work of a general practitioner for one or even two months. The teaching of preventive medicine throughout the curriculum is gaining ground, and it is pointed out that pharmacological instruction might well deal with patent medicines and the mischief they do to patients who attempt to treat themselves at a stage when early diagnosis and proper treatment may prevent serious consequences.

CHRONIC NEPHRITIS IN QUEENSLAND DUE TO LEAD ABSORPTION.

IN 1908 we published a paper by Dr. J. L. Gibson[1] describing fifty-four cases of optic neuritis associated with paralysis of one or both external recti. These cases, all of which had occurred among children in his hospital practice in Brisbane, Dr. Gibson attributed to lead poisoning, and he explained how the children, having got "chalked" white lead paint on their hands from garden or verandah railings, transferred it to their mouths by biting their nails or sucking their thumbs. The relative infrequency of plumbism in the southern States of Australia he thought might be due to the comparative infrequency of verandah railings in the houses and cottages there. How accurate was his interpretation has recently been made evident in two papers published in the *Medical Journal of Australia*.[2] Dr. L. J. J. Nye, the author of one of the papers, points out that in Queensland, during the period 1917-26, 884 persons under the age of 40 died from chronic nephritis, which had been brought about by some cause which either does not exist or does not operate to the same extent in the other States of Australia. He concludes, having weighed all the evidence, that this form of chronic nephritis may be attributed to the slow absorption by children of white lead paint, and adds that the children are poisoned not only in the manner described by Gibson, but as a result of imbibing raindrops from the verandah rails. An adult absorbing 1/32 grain of lead daily would suffer from lead poisoning; in a child the corresponding dose might well be under 1/100 grain. The earliest reference to the subject is in a paper entitled "A form of cerebral disease characterized by definite symptoms: probably a localized basic meningitis," which was read by A. Jefferies Turner at the International Medical Congress of Australia in 1892; it is evident, therefore, that this preventable form of poisoning has been prevalent for about forty years, and one may agree with Dr. Nye's conclusion that "herein lies an extraordinary opportunity for preventive medicine." Probably the most desirable substitute for white lead paint is a combination of titanium white with a proportion of zinc oxide. Titanium white, which may be obtained from ilmenite, has a greater opacity than any other known white pigment, and resists attack by sulphuric acid. Paint made from it is exceptionally resistant to exposure to light, heat, sea water, and seaside air, and it has the further advantage over white lead that it does not as time goes on acquire a dirty drab colour. Its one disadvantage—a relatively small one—is that it dries rather slowly.

[1] Plumbic Ocular Neuritis in Queensland Children, *British Medical Journal*, November 14th, 1908, p. 1488.

TUBERCULOSIS CONGRESS IN NORWAY.

As was briefly mentioned in the *Journal* of November 23rd, the seventh conference of the International Union against Tuberculosis will be held in Oslo next year, from August 12th to 15th. Professor Fröhlich of Oslo, who is president of the Norwegian National Antituberculosis Association, has now issued a circular to members in which additional information is given. The executive committee of the International Union will meet on the morning of August 11th, and the conference will be officially opened at midday on August 12th. The three following days will be devoted to the chief subjects to be considered, the opener of each discussion being followed by ten specially invited speakers. Professor A. Calmette of Paris will describe the B.C.G. method of inoculation against tuberculosis; Professor Bull of Oslo will deal with the application of thoracoplasty to the treatment of pulmonary tuberculosis; and Professor His of Berlin will introduce the subject of the provision of instruction in tuberculosis for medical students and graduates. The principal speakers are being asked to send their communications not later than February 1st either to the Norwegian National Antituberculosis Association or to the International Union, in order that translation and printing may be arranged. Those wishing to attend the congress should notify their intention before May 15th. Arrangements are being made for visits to the principal antituberculosis institutions of Norway and for pleasure trips. A preliminary pamphlet about travel facilities has been issued; it is well illustrated,

[2] An Investigation of the Extraordinary Incidence of Chronic Nephritis in Young People in Queensland, by L. J. J. Nye, M.B., *The Medical Journal of Australia*, August 3rd, 1929, p. 145. The Incidence of Chronic Nephritis amongst Young People in Queensland, ibid., p. 144.

and indicates some of the more attractive excursions which may be undertaken. Further information may be had from the secretary of the International Union against Tuberculosis, 2, Avenue Velasquez, Paris VIIIe.

MENTAL AFTER-CARE ASSOCIATION.

THE Mental After-Care Association has issued an urgent appeal for funds to carry on and extend the work of supervising and assisting convalescent mental patients. It makes use of cottage homes in the country and at the seaside, and has a staff of trained visitors. Although some part of the expenditure is met by local authorities or the persons concerned, a considerable deficit has to be made up out of the funds of the Association, which are entirely derived from voluntary subscriptions and donations. In the past ten years the benefits administered have multiplied six times, while the administration expenses have only doubled. The minimum annual membership subscription is 5s. and donors of £5 become life members. Last year more than 2,000 cases were helped by convalescence facilities in cottage homes, the provision of employment, and the supply of necessary tools and clothing. Further information about the work of this society—the only charity of its kind in the United Kingdom—can be obtained from the secretary, Miss E. D. Vickers, Church House, Dean's Yard, Westminster, S.W.1.

DEATH OF SIR WILLIAM MILLIGAN.

WE have to announce, with much regret, the death, on December 19th, after a long illness, of Sir William Milligan, M.D., M.S., LL.D., consulting aurist and laryngologist to the Manchester Royal Infirmary, and formerly lecturer on diseases of the ear and throat in the Victoria University of Manchester. Sir William Milligan had long been recognized as one of the leading authorities in his specialty in this country. He was president of the Section of Otology when the British Medical Association met in Manchester in 1902, and had held office as president of both the Laryngological and Otological Sections of the Royal Society of Medicine. In recent years he identified himself with the work of the Manchester Radium Institute, and served as chairman of the Lancashire, Cheshire, and North Wales Branch Council of the British Empire Cancer Campaign. We hope to publish a memoir, with portrait, in our next issue.

ADDENDUM

TO THE

COLLECTIVE INVESTIGATION INTO THE AFTER-HISTORY OF GASTRO-ENTEROSTOMY.

SINCE the publication of Parts I, II, and III of the report on this subject in the *British Medical Journal* of December 7th and 14th the following additional statistics have been worked out from the figures contained in the report. It is believed that they will furnish useful information as to the comparative values of the two principal operations performed.

Table XVII in Part I (*Journal*, December 7th) gives the late results of the various operations for duodenal ulcers as obtained from the after-histories. As the main merits of the various operations are represented by the percentage of "very good" results, in that they show the number of patients restored to full health, able to eat anything over periods of some years, and able to resume full work, it was considered advisable to compare the "*very good*" results in the two principal operations performed, together with the respective post-operative mortality. These two operations, which constitute rather more than 95 per cent. of all the operations that were performed, are (1) posterior gastro-enterostomy combined with excision, cauterization, or infolding of the ulcer, and (2) posterior gastro-enterostomy without interference with the ulcer. These statistics have been worked out, and are embodied in the following table.

Duodenal Ulcers.

Type of Operation.	Very Good Results (percentage of the cases with after-histories).	Post-operative Mortality (percentage of all cases).
Posterior gastro-enterostomy + excision, cauterization, or infolding of ulcer	81·2	1·8
Posterior gastro-enterostomy without interference with ulcer	64·5	5·7

These figures show that the operation when combined with removal or infolding of the ulcer gives much better results and a much lower post-operative mortality than the operation in which the ulcer is left without interference.

With regard to the 5 per cent. post-operative mortality for all the operations on duodenal ulcers, the following comparison of the post-operative mortality of the different operations furnishes some interesting results.

Type of Operation.	No. of Cases.	No. of Deaths.	Percentage of Deaths.
Posterior gastro-enterostomy + excision, *cauterization, or infolding* of ulcer	168	3	1·8
Posterior gastro-enterostomy without interference with ulcer	791	45	5·7
Anterior gastro-enterostomy	24	2	8·3

If these death percentages are proportionately averaged the 5 per cent. post-operative mortality for the whole of the cases is obtained. These figures show that the operation when combined with removal or infolding of the ulcer is associated with a much lower post-operative mortality than in the cases of the other operations.

Pyloric Ulcers.

The corresponding statistics have been worked out for the pyloric ulcers, with very similar results.

Type of Operation.	Very Good Results.	Post-operative Mortality.
Posterior gastro-enterostomy + excision, cauterization, or infolding of ulcer	72·4	1·3
Posterior gastro-enterostomy without interference with ulcer	44·7	2·5

With regard to the 2·6 per cent. post-operative mortality for all the operations on pyloric ulcers the following is the comparison of the post-operative mortality of the different operations.

Type of Operation.	No. of Cases.	No of Deaths.	Percentage of Deaths.
Posterior gastro-enterostomy + excision, *cauterization, or infolding* of ulcer	76	1	1·3
[illegible] with-	353	9	2·5
[illegible]	14	1	7·1
Anterior gastro-enterostomy ...	6	1	16·6

If these death percentages are proportionately averaged the 2·6 per cent. post-operative mortality *for the whole of the cases is obtained.*

ARTHUR P. LUFF, M.D., F.R.C.P.

FINAL REPORT OF THE ROYAL COMMISSION ON LOCAL GOVERNMENT.

IN our issue of December 7th (p. 1068) we described in general terms the contents of the Final Report of the Royal Commission on Local Government,[1] and noted that the Commission, in the first part of that report, continues the examination which it had begun in its second interim report, issued more than a year ago, of the proper distribution of certain functions among local authorities. Many of the functions passed under review have no relation to public health and its administration, and among those which have some such relation two are deliberately excluded from consideration—the superannuation of local government officers, on the ground that a Departmental Committee reported on this subject in 1928, and education, because, in the opinion of the Commission, if further inquiry in this sphere should be deemed necessary, it could more appropriately be made by a committee specially appointed for the purpose.

The administration of the Food and Drugs (Adulteration) Act, 1928, which consolidated, without amendment, previous Acts together with the appointment of public analysts, and the administration of the Milk and Dairies Acts, are among the more important functions examined. With regard to the former, it seems clear that there are a good many boroughs whose population is too small and whose financial resources are too restricted to enable them to make satisfactory provision for the execution of the work required, and the Royal Commission accordingly says:

"It appears to us that the arguments are conclusive in favour of a simplification in the distribution of this service, and that the full powers and duties (comprising the appointment of an analyst as well as the taking of samples) should be assigned to authorities having jurisdiction over considerable areas; and we think that the councils of counties and county boroughs are the most suitable authorities for this purpose. It is not, however, our intention that the borough councils who are now exercising these powers should entirely cease to do so; which, indeed, would clearly not be in accordance with the public interests. On the contrary, it is, in our opinion, desirable that they and the councils of other county districts should continue through their medical officers or other officers to take samples of food and drugs from time to time for the purpose of analysis, and should, when necessary, cause proceedings to be taken with a view to securing due observance of the Act. In order that councils of county districts may be encouraged and assisted in the performance of these functions a county council should have power to contribute towards the cost."

With regard to the Milk and Dairies Acts, and Orders made thereunder, evidence shows that the arrangements in accordance with which this service is administered are extraordinarily complicated, but that they afford ample facilities for varying such arrangements with reference to various parts of the service as experience proves this to be desirable or necessary. The various associations of local government authorities had differing suggestions for simplification to offer; but as the Milk and Dairies Order, 1926, has been in operation for so short a time, as indeed some of its provisions have not yet become operative, the Commission do not make any recommendation for further reassignment of functions at present. Experience seems to be showing, however, that some modifications will have ultimately to be made.

Many of the difficulties in connexion with the distribution of certain functions between local government authorities can be surmounted by suitable co-operation among such authorities. The extent to which this co-operation already exists is considerable, but, in the view of the Royal Commission, "there is room for still further co-operation, and much evidence points to the possibility of developments in this direction." So far it is mainly with regard to the provision of certain institutions—schools and hospitals—that authorities have acted jointly, but there are a number of other directions in which authorities which are in a position to assist one another might facilitate and improve the provision of certain services. This is particularly the case with regard to water supplies. The more readily accessible sources of such supply have been appropriated, and as the consumption of water is still growing, and likely to grow, much systematic foresight is required. In this respect, certainly, wide regional advisory committees are needed. Two such committees have already done useful work—one for South-West Lancashire and one for Nottinghamshire—and the report commends to the attention of all local authorities the desirability of taking active steps to secure the creation of regional advisory committees throughout the country generally.

Urban district councils possess many powers which rural district councils have not. There are a number of enactments, however, under which the functions of the former may, in certain circumstances, be assigned to the latter. The difference between the two classes of authority is often a distinction in name only, as a large number of rural areas are rapidly becoming urbanized; yet the process by which a rural district may acquire urban powers is laborious and time-wasting, both to the local authority and to the Ministry of Health.

It is not proposed that the *duties* of urban district councils shall be imposed upon those of rural districts; but in regard to *powers*, the Commission agrees that it is necessary and expedient that these should be much more closely assimilated, and a long list is given of various sections of the Public Health Acts, the administration of which should be within the powers of rural district councils, and should be entrusted to them generally by statute, without the necessity for the procedure of formal adoption or application to a central department. The appointment of a parochial committee in the part of a rural district which is urban in character is suggested. With regard to the functions of parish councils and parish meetings, the report says:

"Apart from the question of scavenging and provision and maintenance of village halls, there does not appear to be any demand for alteration in the functions assigned to parish councils and parish meetings.

"As regards scavenging, we consider that this is a sanitary service, responsibility for which should remain with the rural district council, but in the event of the district council declining to provide this service in a parish which desires it and is willing to bear the cost, we recommend that the Minister of Health should be empowered either to require the district council to act at the expense of the parish, or alternatively to authorize the parish council themselves to provide the service. We think, however, that difficulties would be less likely to arise if district councils more commonly appointed parochial committees for services of this kind."

In evidence before the Royal Commission, Sir Arthur Robinson, on behalf of the Ministry of Health, gave reasons why there should be some alteration of the present procedure whereby a district may become incorporated as a borough. This evidence had reference to a memorandum, which had been agreed between all the departments concerned—the Privy Council Office, the Home Office, the Ministry of Health, and the Board of Education. The proposals have attracted considerable attention, because it was agreed that the status of a borough tended to foster civic spirit, and so to help local government, and it was stated that "it might be expected that the number of boroughs would steadily increase, and that the rate of increase was likely to be higher in the future than in the past." At present a borough is created by the grant from the Crown of a charter of incorporation. It was proposed that, while leaving existing boroughs untouched, each urban district of sufficient size should be empowered by statute to constitute itself a borough, provided that the resolution were confirmed by an Order of the Minister of Health, laid before Parliament. The reasons given for an alteration of the procedure for incorporation are generally accepted as good, but proposals for the creation of a new kind of statutory borough have not been favourably received, partly from sentimental, partly from practical considerations. The conclusion of the Royal Commission is that the charter system should be retained, but that (1) as a rule of practice, a minimum population of 20,000 should normally be a condition precedent: (2) in lieu of a petition signed by a majority of inhabitant householders the petition should be made by the local authority; (3) the

[1] Final Report of the Royal Commission on Local Government. London: H.M. Stationery Office. 1929. 3s. net.

efficiency of administration and financial capacity of the area in question should be primary considerations, and that therefore any local inquiry into a petition should be held by an inspector of the Ministry of Health.

Four other matters dealt with in the report are of importance to the medical profession and in relation to public health administration. These are: (1) co-option on committees of local authorities; (2) disqualification of members of local authorities; (3) the position of the clerk to the local authority in relation to the medical officer of health; (4) security of tenure of officers. On all these subjects representations have recently been made by the British Medical Association to the Ministry of Health. The representations with regard to the second and third of these points are referred to in the report itself.

Members of the medical profession in active practice probably experience more than the average amount of difficulty in taking their full and proper share in public life as members of a local government authority. The effects of party controversy and of undesirable publicity, and the virtual impossibility of regular attendance at meetings, are intensified in the case of most medical practitioners. Yet it may truly be urged that among them are to be found those whose judgement on matters of public health, of maternity and child welfare, of education, would be of the very greatest value. It is important, therefore, to see that opportunities for the use of their knowledge and experience in particular spheres of public administration should not be curtailed, and that no unnecessary obstacle should be placed in the way of their becoming members of any local government council or committee.

Prior to the Local Government Act, 1929, the co-option by a council of persons who had not been elected in the ordinary way was obligatory in respect of education committees, mental deficiency committees, maternity and child welfare committees, agricultural committees, and was permitted on library committees. Under the Local Government Act such co-option is obligatory upon guardians committees, and is permitted on public health committees and their subcommittees, and on subcommittees of mental deficiency committees. All these opportunities for service should be noted by the profession, and local authorities may well be urged, with some insistence, to adopt the method of co-option, especially in connexion with work in which medical expert knowledge would be peculiarly valuable. No exception can be taken to the recommendation of the Royal Commission that co-opted members should not exceed one-third of the total number of any committee, and it would be well if the suggestion of the County Councils' Association could be enforced—that only persons possessing special knowledge and experience should be eligible for appointment. It is mainly owing to a neglect of this requirement that the principle of co-option has fallen into disrepute in certain areas. It is perfectly reasonable, too, that co-opted members should be subject to the same disqualifications as elected members in regard to voting on matters affecting their personal interests, and, indeed, that any disqualifications for membership should apply universally. The Royal Commission states that "the law relating to disqualification requires amendment to meet conditions now prevailing." This is particularly the case with regard to the medical profession in view of the fact that almost every year its members are being brought into closer relation with the public health schemes of central or local authorities. The conclusions of the Royal Commission on this matter do not appear to be quite clearly stated in the report. On the one hand, it is said, "Disqualification must be so defined that it will not unnecessarily exclude a large number of persons from participating in local government. With this in view, the situation would best be met if disqualification were applied to voting rather than to membership." This would be satisfactory; but, as regards medical practitioners, the report says:

"... we consider that a doctor who is remunerated by fees for specific services rendered under certain Acts need not be disqualified for membership of a local authority. On the other hand, a doctor who is rendering not necessarily continuous but continuing service in a specific capacity, such as a medical officer at a maternity and child welfare centre, is more clearly in a contractual relation with the local authority, and should therefore be disqualified from membership."

Apart from its relation to the previous statement quoted above, this paragraph is not itself clear in all its implications, and no doubt the British Medical Association will take the matter further in consultation with the Ministry, and with the hope that suitable action will be taken. This is the more urgent in that the effect of the Local Government Act will be to disqualify as from April 1st next a number of medical practitioners who are at present members of town, county, or district councils.

The question of the position of the town clerk in relation to the medical officer of health threatened at one time to become a very important and awkward matter in view of circumstances which arose in the specific cases of Smethwick and of Bournemouth. Arising out of these cases a considerable correspondence took place between the Ministry and the Association, and the substance of the last letter from the Ministry is set out in the report of the Royal Commission. This can be regarded as relatively satisfactory, and was accepted by the Association as being "a much closer approximation to the position the Council wishes to maintain on behalf of medical officers of health and the work of their departments than either of the Ministry's previous letters, or the paragraphs contained in the section headed 'Local Government and Local Finance' in the fifth annual report of the Ministry, to which the Council took the strongest objection." In view of the importance, actual and potential, of this matter it may be well to refer to the complete correspondence contained in the Minutes of Council of July 23rd, 1928 (pp. 306 and 297), and to quote the relevant conclusions of the Royal Commission.

"With regard to the position of the clerk in relation to the other officers of a local authority, we are disposed to think that the difficulties in actual practice are not so acute as might be inferred from the divergent views expressed in the evidence. At the same time, we must record our opinion that some of the technical officers have claimed a degree of independence which should not be conceded. It is, in our judgement, imperative that one officer of the council should be in a position to survey the various activities of the authority, and to secure that they are properly focused and co-ordinated, with reasonable uniformity and continuity. The most suitable officer to undertake this responsibility is the clerk, and we have been unable to satisfy ourselves that the administrative machinery of local government could be worked on any other basis.

"This principle is, however, quite consistent with some of the suggestions advanced on behalf of the technical officers. For example, the clerk need not, and should not, interfere with the technical staff on technical questions; and, in particular, the responsibility of the chief financial officer for financial administration should be clearly recognized; further, technical officers should not be debarred from direct access to the committees of the council. The questions arising on such points become largely academic, once the principles are established that the clerk must be kept informed of the activities of the various departments, and of the reports which the chief officers thereof make to the council or committees; that the clerk is responsible for seeing that proper co-operation exists between the various departments, and for advising the council thereon; and that the clerk is the channel through which the authority conduct official correspondence.

"We may sum up our conclusion by saying that in our opinion the clerk to the council must be the principal officer of a local authority and responsible for securing co-ordination between the several departments."

As regards the security of tenure of local government officers, it is well known that, with certain limitations, whole-time medical officers of health and whole-time sanitary inspectors are removable only with the consent of the Minister of Health. The Society of Medical Officers of Health represented to the Commission that the limitations above referred to should be removed so that the security enjoyed by most medical officers of health should be extended to all; and certain other associations of local government officers sought for their members a like security. The sense of insecurity has been much intensified by the recent case of Brown v. Dagenham Urban District Council. The effect of the judgement in this case was that, by virtue of Section 189 of the Public Health Act, 1875, a council could, in law, dismiss an officer at a moment's notice whatever contract might have been made with him as to notice.

The recommendation of the Royal Commission is stated thus:

"We do not recommend an extension of the practice that the appointment or dismissal of certain officers should require the approval of a central department. . . . We consider that there should be an amendment of the law so as to provide that, notwithstanding the provisions in Section 189 of the Public Health Act, 1875, and other analogous enactments empowering local authorities to dismiss their officers at pleasure, it should be competent for local authorities to enter into contracts with their officers providing for reasonable notice of termination of any such contract on either side, and that such contract should be binding on both parties."

In conclusion, it is interesting to note the evidence given about the methods of recruitment, promotion, and transfer of local government officers. The report says: "It is open to question whether the present methods of recruitment are calculated to ensure that local authorities shall have at their disposal officers of the type needed." "The local government service would benefit if the facilities for interchangeability were enlarged." Indeed, though the appointment of a Departmental Committee to inquire further into the subject is recommended, it may be said that the Royal Commission distinctly favours the principle on which the British Medical Association's efforts for a salary scale for members of the public health service are based—namely, that the service should be considered as one whole, offering a wider and more attractive career than a restricted service with any single local authority could possibly afford.

Scotland.

Edinburgh Memorial to Sir William Macpherson.

In memory of Major-General Sir William Grant Macpherson, K.C.M.G., C.B., LL.D., colonel-commandant of the Royal Army Medical Corps, who died in October, 1927, and "in humble gratitude for his great and distinguished services," the officers of the Corps have erected a bronze tablet in the north wall of St. Giles's, Edinburgh. The unveiling and dedication of the tablet was an occasion of impressive ceremony in the Cathedral on December 8th, when, in addition to Lady Macpherson and members of the family, a large congregation, representative of the city, the university, and the military authorities, assembled. The memorial was unveiled by General Sir William Peyton, general officer commanding in Scotland, dedicated by the Rev. C. L. Warr, Dean of the Thistle, and received on behalf of the Cathedral board by Lord Provost Whitson. A short address was given by Lieut.-General H. B. Fawcus, Director-General Army Medical Services, who spoke of the many distinctions of Sir William Macpherson's career. A true Scot, born in Ross-shire and educated in Edinburgh, it was appropriate, said General Fawcus, that his name should be commemorated in the great church of the Scottish capital. He mentioned that "Tiger Mac"—a name given to him, not because of anything fierce or rude in his nature, but as a tribute to his energy, thoroughness, and definite point of view—was mentioned nine times in dispatches, and that France, Italy, and the United States, as well as his own country, had conferred honours upon him. His carefulness and ability as a historian were enshrined in *The Medical History of the War*, his zeal and integrity were a clear-cut recollection to his colleagues and friends who served with him and who remembered his incisive catechism at inspections, and his keen interest in athletics and sport of various kinds was a joy to watch. General Fawcus also said that it was fine to observe how the dogmatism which Sir William used to assume in earlier days—the natural result of the intense interest with which he dealt with any subject—was pushed aside like a mask when greater intimacy disclosed the sympathy, the humanity, and the friendliness of the real man. Among those present at the service were many prominent figures in Edinburgh life, including Lord Alness (Lord Justice-Clerk) and Lords Morison and Hunter, of the Scottish judicature, Sir Thomas Holland, Principal of Edinburgh University, Dr. R. A. Fleming, and Mr. Alexander Miles, Presidents respectively of the Royal Colleges of Physicians and of Surgeons, Sir Robert Philip, Professor John Fraser, Sir Harold Stiles, Sir David Wallace, and Sir Leslie Mackenzie, and among many army officers, General H. P. W. Barrow, Director of Hygiene, War Office, Colonel L. Wood, D.D.M.S., Scottish Command, Lieut.-Colonel P. N. Nissen, Lieut.-Colonel J. A. Kempthorne, Colonel D. Mason Macfarlan, and Major Irvine-Fortescue. There was a detachment from the Officers' Training Corps of Edinburgh University and of Fettes College, Edinburgh, where Sir William Macpherson spent his school days, and the 155th Lowland Field Ambulance, the 11th General Hospital, and the Edinburgh and Midlothian Voluntary Aid Detachment were represented. At the close of the ceremony a piper playing "Flowers o' the Forest" made his way down the middle aisle and through the chancel. It was in Edinburgh, during the Annual Meeting of 1927, that Sir William Macpherson was last seen by his colleagues on the Council of the British Medical Association, and by members of the Association's headquarters staff, with whom he had worked for six years on terms of friendship.

Hospitals and Road Accidents.

The expenditure of infirmaries in regard to road accidents was referred to by Sir David M'Cowan, who presided at the fifty-fifth annual meeting of the Glasgow Western Infirmary Samaritan Society. He said that while the responsibilities of this infirmary were steadily increasing, one which had brought a special burden on these hospitals was due to the change over that had taken place from railroad transport to road transport. Accidents on the roads were now causing a serious problem, because road accidents were very numerous and appeared to be on the increase. Colonel J. A. Roxburgh, chairman of the Western Infirmary, also referring to this matter, said that in smaller institutions, of, say, fifteen or twenty beds, two or three motor accidents at the week-end not only caused great extra expense, but dislocated the ordinary work of the hospital. There was a further difficulty in getting such people to give an adequate sum to the hospital which treated them. He did not know whether, if compulsory third party insurance for all motor owners were instituted as was now proposed, it would help hospitals to any extent, but he considered that some solution of the difficulty must soon be found.

Vital Energy in Food.

A paper was read, on December 9th, by Dr. Chalmers Watson before the Royal Society of Arts in Edinburgh, dealing with the subject of irradiation in medicine. The lecturer said that the relation of rays to matter was a concern of modern physics and also of modern medicine. The theory of the atom had in recent times been replaced by the theory of the electron, and with the acceptance of the electron theory many current views of animal and vegetable life required revision. The discovery of the *x* rays by Roentgen in 1895 had been the starting point of this development, and these rays had proved an inestimable boon in the diagnosis of disease, and had also added materially to the resources of treatment. It was further recognized that most of the benefits to health obtained from sunshine were due to rays beyond the violet end of the visible spectrum, and the sunshine in many British health resorts had a large supply of ultra-violet rays. Finsen of Copenhagen had been the pioneer in demonstrating the curative influence of these rays on some skin lesions, and later modifications had demonstrated their value in a wide range of disorders in which there was some derangement in the metabolism of calcium and phosphorus, such as rickets, malnutrition, disorders of pregnancy, lactation, and dentition. A more recent development had been the application of irradiation to medicinal products and foodstuffs, such as milk and flour, though how long the special qualities imparted to the substance by these means persisted was an open question. The lecturer described how milk was irradiated by allowing it to flow in a fine film over a tube in which ultra-violet rays were produced, the exposure lasting some thirty-five seconds, and impairing neither the taste nor the

nutritive value. The main result was to impart a definite antirachitic property which would remain active for at least several days. The antirachitic property was commonly supposed to be due to the formation of vitamin D. The possibility that the action might, to an important extent, be associated with energy on the lines of the physicist did not appear to have been yet investigated. At all events, the curative value was readily attested by the results of radiological examination of the bones, and recovery in rickets was promoted more surely and quickly by irradiated milk than by any other known means. He considered that the question of vital energy in foods was of great importance. There might be an intermediate stage quite apart from evidence of decomposition in food, in which, nevertheless, the vital energy of the food had been largely lost through age or methods of preservation, and the teaching of modern science appeared to point in this direction. An extension of the demand for home-grown fresh foods was therefore amply justified, both on the grounds of patriotism and of science.

Edinburgh Royal Infirmary.

A meeting of the honorary staff of the Royal Infirmary of Edinburgh was held in the institution on December 12th for the purpose of making a presentation to Mr. William S. Caw, clerk and treasurer of the Infirmary. Mr. Caw retires on December 31st on the completion of forty-nine years' service to the institution. Dr. A. H. H. Sinclair presided, and the presentation was made by Sir Byrom Bramwell, one of the senior consulting physicians. The presentation consisted of a silver salver in the form of one of the salvers of the Traprain treasure, bearing a suitable inscription. This gift was accompanied by a cheque for a handsome sum of money. Sir Byrom Bramwell referred to Mr. Caw's long and faithful service, which included three and a half years during the war, when he also acted as superintendent of the institution, and he emphasized the fact that members of the honorary staff had come to regard Mr. Caw rather as a helpful colleague than as merely an official. Mr. Caw, in acknowledging his appreciation, referred to several outstanding events which had taken place in connexion with the hospital during his term of office.

England and Wales.

The Jewish Health Organization.

THE activities of the Jewish Health Organization of Great Britain for the year 1928–29 form the subject of an admirable report recently issued on behalf of the council by Drs. Redcliffe N. Salaman and A. H. Levy. During the five years that have elapsed since its formation the Jewish Health Organization has undertaken increasing responsibilities with regard to child guidance, medical research, and health education, and under its auspices have been published a number of valuable scientific papers on the problems with which its workers have concerned themselves. The work of the Child-Guidance Clinic, which was founded by the organization two years ago, is discussed in a paper which has been accepted for publication in the *British Journal of Medical Psychology*; and of the Vision Investigation Committee in papers published in the *British Journal of Ophthalmology* in April and December, 1928. The work of this committee is still proceeding, and further investigations under the auspices of the organization include an anthropometric study of Jewish school children in connexion with a similar study now being conducted by the Ministry of Health and the Board of Education; and an inquiry, planned at the instigation of the Association of Jewish Friendly Societies, into the types of disease prevailing among the members of its constituent bodies. During the year under review definite progress has been made in the work of the Child Guidance Clinic, but in their report Drs. Noel H. M. Burke and Emanuel Miller, the psychiatrists in charge, suggest that it would be desirable if the facilities of the clinic were used for patients somewhat younger than those attending at present. The problems of adaptation, it is now generally recognized, arise either in early childhood—that is, during the period of the emergence of self-consciousness and the struggle to accept social values in behaviour—or later, at adolescence, when the changing physiology makes additional claims on the child, both mental and physical. The clinic data indicate that a large number of cases are allowed to pass unnoticed until the maladjustments or other psychological abnormalities reach a sufficient degree of intensity to attract the attention of parents or teachers. It is noteworthy that the experience so far gained in the clinic does not warrant the view that heredity plays a large part in the etiology of the maladjustments in question; some of the good results obtained in the clinic have been with children having a thoroughly bad family history. A feeble constitution in the child itself, as observed in its physical and mental make-up, is believed to be a far more important early indication for a poor prognosis.

After-Histories of Tuberculous Patients.

The London County Council publishes every year particulars of the after-histories of patients who received residential treatment under its tuberculosis scheme and were discharged five years previously. During 1923 the number of adults discharged from treatment was 4,115 (2,560 men and 1,555 women). In 247 cases the diagnosis of tuberculosis was not confirmed, and of the remainder 337 were not traceable, and 135 were discharged from observation hospitals within a few weeks of admission and were not transferred to sanatoriums. The number of cases investigated at the end of five years was therefore 3,396. These are classified on the basis of the selection of patients for residential treatment—namely, Class A, sputum-negative cases; Class B, sputum-positive, divided into three sub-classes, B 1 (with slight constitutional disturbance and obvious signs of very limited extent), B 3 (with profound systemic disturbance or constitutional deterioration, or with grave complications), and B 2 (comprising all cases not falling into groups 1 and 3). Classes A and B 1 may be considered as early cases; B 2 as moderately advanced, and B 3 as far advanced. In addition there were 245 non-pulmonary (surgical) cases. The mortality records after five years gave the following result.

Class.	Males.			Females.		
	No. of cases.	Alive five years after.	Dead.	No. of cases.	Alive five years after.	Dead.
		Per cent.	Per cent		Per cent.	Per cent.
A	216	80 1	19.9	168	77.4	22.6
B 1	181	64.1	35.9	103	61.2	38.8
B 2	1,136	34.1	65.9	533	29.3	70.8
B 3	547	6.8	93.2	237	7.2	92.8
Surgical ...	140	71.4	28.6	105	85.7	14.3

About 70 per cent. of those surviving in the A and B 1 classes were at work or fit for work but unemployed.

With regard to children, during 1923 the number of children discharged from residential institutions after having received at least one period of residential treatment was 654. Allowing for certain deductions, the after-history of 474 (196 pulmonary and 278 non-pulmonary) was investigated, and 133 of the pulmonary cases and 250 of the non-pulmonary were found to be still alive. The analysis is as follows:

Class.	Total.	Alive five years after discharge.	Dead.
A	135	88.7 per cent.	11.3 per cent.
B 1	7	71.4 ,,	28.6 ,,
B 2	18	11.1 ,,	88.9 ,,
B 3	35	14.3 ,,	85.7 ,,
Surgical	278	89.9 ,,	10.1 ,,

Chancellorship of Bristol University.

On December 13th the Right Hon. Winston Churchill, P.C., C.H., was installed as Chancellor of the University of Bristol, in succession to the late Lord Haldane. The ceremony took place in the Great Hall, and it is interesting to record that Mr. Churchill wore the black and gold robes which had been used by his father, Lord Randolph Churchill when Chancellor of Manchester University. The Right Hon. Henry Hobhouse, the senior Pro-Chancellor, welcomed the Chancellor on behalf of the University and installed him, presenting him with a key of the University Seal and a copy of the University Charter. The Vice-Chancellor presented Mr. Churchill with a patent of the degree of Doctor of Laws, after which the new Chancellor proceeded to confer the honorary degree of Doctor of Laws upon Miss Margaret Bondfield (Minister of Labour), Mr. Philip Snowden (Chancellor of the Exchequer), Admiral Sir Roger Keyes, Mr. Walter Runciman, M.P., and Dr. Thomas Sibly (Vice-Chancellor of Reading University), and the honorary degree of Doctor of Letters was conferred upon Mr. Walter de la Mare and Dr. Vaughan Williams. On the morning of December 15th Mr. Churchill addressed the undergraduates of the University at the University Union Club, and received a truly remarkable welcome from them. In the evening the Chancellor and Mrs. Churchill held a public reception at the University and City Art Gallery, the buildings of which adjoin, and on occasions such as this have communicating doors thrown open. Some 2,000 guests attended the reception.

Union of South Africa.

[FROM OUR CORRESPONDENT IN PRETORIA.]

Bantu Health and Shortage of Native Labour.

According to the 1928 convention between the Union and the Portuguese Republic Governments, the number of natives recruited in Portuguese territory for work on the Transvaal mines is being reduced annually by 5,000; from 1933 onwards only 80,000 of these natives will be employed instead of the 100,000 that were in employment until last year. Already the shortage of native labour in the Union is being acutely felt, since the developing mines and industries are requiring more and not fewer labourers. The Union Government is now considering ways and means of overcoming this shortage, particularly as the agricultural industry is likely to suffer most from any shortage; natives on the farms are being attracted to the better paid work on the mines. Two methods of obtaining more native labour are being considered, and both involve important health problems. The most obvious method is to sanction recruiting in the hitherto prohibited tropical regions north of latitude 22 degrees south. The other method is to take steps to promote the multiplication and improve the general health of the Bantu population of the Union so as to reduce the present high rate of rejection for unfitness for industrial work.

Tropical natives employed on the mines in the early days of mining had a very high mortality. It was for this reason that their recruitment was prohibited by law in May, 1913. At that time it was generally believed that their greater susceptibility to pulmonary complaints was due to lack of acclimatization to the cold conditions prevailing in the winter at the high altitude of the Witwatersrand. Subsequent investigation has indicated that the cooling power of the Rand atmosphere has little to do with the matter. The degree of susceptibility to pulmonary disease of the Bantu appears to depend very largely on the amount of his previous contact with European civilization and, therefore, with European disease. Since the bulk of native labourers are treated with pneumococcal vaccine on arrival at the gold fields, immunity comparable with that possessed by the average European will probably be conferred on natives, even from the tropical regions where European trade has hardly penetrated. The greatly lessened incidence of pneumonia on the mines after the removal of the tropical natives is not now attributed primarily to this removal; the introduction of pneumococcal vaccination at about the same time and the greatly improved sanitation in the compounds are considered to have been of greater importance. Another important factor has been improved feeding, more particularly insistence on an adequate vitamin ration. In the early days the native subsisted almost exclusively on porridge made from crushed mealies, often kiln-dried, with a negligible vitamin content. Subsequently regular rations of vegetables, meat, germinated beans, and fruit were introduced to supplement the basic mealie-meal diet. The objection to recruiting of tropical natives can therefore no longer be justified on medical grounds.

Disease in the Transkeian Native Territories.

The poor health of the Bantu population of the native reserves of the Union is beginning to attract general attention. In spite of an active segregation policy, leprosy has not so far appreciably diminished. Typhus has for long been endemic in many native districts, and has recently shown signs of increase. Evidence is continually accruing of the high incidence of tuberculosis among the "raw" natives. During the past three years an investigation into this incidence, supported jointly by the Union Government and the Transvaal Chamber of Mines, has been in progress. It had been variously suggested that industrial phthisis contracted by mine natives had resulted in the infecting with tuberculosis of the territories to which they returned. This has been discredited by the relatively large percentage of positive tuberculin reactions among raw natives, and the comparative rarity of the "natural" or "infantile" type of the disease among them. Tuberculosis must apparently be considered to be endemic in the native territories. Its persistence and increase along with the persistence and increase of other conditions such as leprosy and typhus are to be associated rather with the general poverty and malnutrition of the people. The inadequate and deficient diet of the native children must of necessity result in an undermining of the constitution, facilitating attack later by the diseases of poverty such as leprosy, typhus, and tuberculosis. Maize has always been the staple article of diet, supplemented to a very slight extent by milk and vegetables in the rainy seasons. But the increasing congestion of the population and the recent prolonged droughts have resulted in less of these adjuvants being available.

Fifty years ago the native territories were sparsely populated and self-supporting. A settled European administration with an almost complete absence of inter-tribal strife has resulted in a population too dense to be supported entirely by the crude methods of farming hitherto adopted within the reserves. The Cape native territories are 16,000 square miles in extent; the population of just over a million persons owns approximately a million head of cattle, and two million sheep and goats. The cattle are almost invariably the poorest of scrub and produce very little milk. A partial solution of the relative overpopulation of the reserves has been the increasing labour requirements of the growing mining and other industries of the Union; the territories have become a vast recruiting area for unskilled labour. Heretofore the mines have obtained more than half their complement of native labour from the neighbouring Portuguese colony. With the restriction of this supply a great strain is being thrown on the labour resources of the Union native reserves, and under the present conditions an adequate supply of fit native labourers is not available. Improvement of the general health of the native population of the Union is therefore becoming necessary for economic as well as humanitarian reasons, and the Government is interesting itself more and more in native welfare. Agricultural experts have been sent to instruct the natives in improved methods, and thoroughbred bulls and rams have been provided to tone up the native herds and flocks. By such means it is hoped that greater returns will become possible from the smaller areas on which native families now have to subsist. This is a wise move, since the health of these people will very largely depend on better food supplies

resulting from improved methods of farming. More direct attention is also being paid to native health. With this end in view the Union Health Department last July stationed an assistant health officer at Kingwilliamstown, at the lower end of the Cape native territories, with the object more particularly of supervising native health conditions.

Typhus among the Native Population.

As mentioned previously, typhus is on the increase in the native territories, and has been especially prevalent during the present spring. The prevalence may be partially due to a wearing off of the immunity acquired during the very extensive outbreaks which occurred during the period 1919 to 1923. The main cause is, however, undoubtedly the increasing poverty resulting from prolonged droughts and over-population. It is noteworthy that the incidence is highest in the districts where the population is both dense and poor. Thus in the thickly populated and poverty stricken district of Glen Grey the typhus notifications during the year ended June, 1929, were 205, and in the past four months (July to October) ninety. The recorded incidence is probably much below the actual incidence, for the native headmen will not, in general, report outbreaks unless the cases become very serious and deaths occur. Moreover, unless deaths occur, the cases often do not become known to the headman. Hygienic propaganda is doing some good; the more educated natives have been told, and to some extent believe, that typhus is louse-borne. When outbreaks occur deverminization of all contacts is carried out and the natives no longer object to this procedure. Some of the European magistrates in the territories have devoted much time and energy to propaganda against lousiness with gratifying results. The non-European Health Society issues a magazine which circulates largely among native teachers, and does most useful propaganda work.

Correspondence.

"TENNIS ELBOW."

SIR,—The pathology of "tennis elbow" has long been a question of surmise and conjecture, and its treatment therefore varied, unstandardized, and empirical. Many views on the pathology have been expressed, and all methods of treatment have had their successes and their failures. It is my desire to establish a definite view of the pathology, and to explain the inconsistencies in the results of treatment. My view is based upon the experience of many cases treated by various physical methods apart from open operation; upon eight cases not responding to the usual methods of physical treatment, and subsequently treated by open explorative operation; and, finally, on personal experience of the condition. All cases have been investigated by *x* rays as well as clinically.

The theories of causation that have been advanced are, among others, adhesions, arthritis, periostitis, and chronic muscle strain. It is evident that a clinical picture so constant as "tennis elbow" is scarcely likely to have a multitude of pathologies. The symptoms are: pain in the region of the radio-humeral part of the elbow-joint, radiating down over the bellies of the extensor muscles of the forearm, often to the middle and ring fingers. This pain is greatest when the elbow is fully extended and the forearm completely supinated, the wrist extended, and the fingers fully flexed in tight grip. It is felt especially when a heavy object is grasped and picked up, with the elbow extended and the forearm rather supinated. The heavier the object picked up, and the more extreme the extension and supination, the greater the pain. Other signs are: tenderness of the radio-humeral joint, both in front and behind, and especially in front of the tip of the external epicondyle; and occasionally swelling at the back of the radio-humeral joint. In tennis the strain occurs in a back-hand stroke, in which the elbow-joint is fully extended and the forearm pronated, and also in the forearm drive, when the elbow is extended and in full supination. It is the over-extension strain that matters, whether the forearm be supinated or pronated. In a great number of cases *x*-rayed by me bone and joint changes have been consistently absent. This would negative the periostitic and arthritic theories of the causation of tennis elbow. Elbow cases showing definite osteo-arthritis of the joint give a quite different clinical picture.

In eight protracted cases of tennis elbow I explored the condition with the limb completely exsanguinated; with tourniquet applied it was possible to get a complete view of the radio-humeral joint and the surrounding structures. In no case was any abnormal periarthritic condition discerned. The radio-humeral joint was opened both in front and behind, but the external lateral ligament in its connexion with the orbicular ligament was preserved. In all cases hyperaemic fringes of synovial tissue were discovered both in the front and back of the joint. These were hyperaemic, although all other tissues had been rendered bloodless by the Esmarch desanguinating bandage. These fringes were removed at the operation. In one case there was exfoliation of cartilage, although there were no clinical or *x*-ray signs of arthritis. In most cases there was a synovial distension of the joint extending upwards and outwards towards the external epicondyle (just as a semimembranosus bursa may be an extension from the knee-joint). This condition has been described as a separate bursa (Osgood), but I am convinced that it is merely a distension of the radio-humeral joint, lying in front of the external epicondyle, and compressed by the extensor carpi radialis longior muscle in extension movements of the wrist, and thereby responsible for some of the characteristic pain on wrist extension and grip in "tennis elbow." All cases were cured by the open operation.

From my operative experience I confidently advance the opinion that "tennis elbow" is always a traumatic synovitis of the radio-humeral joint, the trauma being chronic from repeated slight injuries and the failure of the patient to rest the elbow in the earliest stages, and due especially to excessive extension of the elbow-joint and supination of the forearm. It is agreed that forced extension of the elbow with the forearm in pronation may also produce the same condition—namely, over-driving of the joint and pinching of the synovial fringes. There is no *x*-ray evidence whatever to support the theory of periostitis, and the suggestion of chronic muscle strain is negatived by the non-occurrence of similar conditions in association with other joints. The pain felt in the elbow and forearm on tightly gripping something with the fingers, and worse in proportion to the degree of extension of the elbow and supination of the forearm, is explained as being due in part to the pressure on, or constriction of, the synovial pouch protrusion in front of the epicondyle, and in part to the increase of interosseous pressure in the inflamed radio-humeral joint and the nipping of congested synovial fringes.

My theory of the causation of tennis elbow will explain the well-known inconsistent results of treatment. Numerous observers will quote good results from individual methods, such as rest, restrictive splint, massage, electrolytic needle, manipulation (bone-setting), etc. It is an established fact that well-known bone-setters are very successful in some cases of this condition by their manipulative treatment, while in others they are as certainly unsuccessful. I have had successful results with manipulation, but in others failure; all depends on the stage at which manipulative treatment is undertaken. Take, for comparison, a similar condition of synovitis of the knee-joint, and these discordant facts will be explicable. There is a period in the treatment of the knee when rest is indicated for the subsidence of pain and inflammation: if this is too prolonged, adhesions result, and manipulation is required to break down adhesions. In the early stage a tennis elbow requires rest; if this is too prolonged adhesions form, and a short, sharp, firm manipulation, bringing the elbow into full extension with the forearm fully pronated, will be required to relieve pain. All the various methods of treating tennis elbow, at times successful and at others not, can be understood in their successful or unsuccessful application by reference to the similar condition in the knee or any other joint if the essential pathology be remembered as a traumatic synovitis.—I am, etc.,

London, W., Dec. 1st. W. H. TRETHOWAN, F.R.C.S.,
Orthopaedic Surgeon to Guy's Hospital.

SIR,—The editorial comment in the *British Medical Journal* of December 14th (p. 1122) on the discussion of tennis elbow by the Section of Orthopaedics of the Royal Society of Medicine concludes with these words: "The impression left on our mind by this discussion is that the etiology of tennis elbow is various, its pathology obscure, and its cure uncertain." As one who was not present at the discussion, and who does not fully agree with the conclusion stated, I venture to feel that the following notes may be of some interest.

While the elbow-joint, in common with all other joints, is liable to many forms of injury at games, my experience points to a very definite clinical entity, to which the term "tennis elbow" should be applied. The following is a description of this entity.

First, there is pain in the region of the elbow-joint—for the main part a dull, aching sensation, awakened to a twinge of acute agony by certain movements. This twinge may be so acute that the victim drops the racket or teapot, or whatever he may be holding when the particular movement happens to be performed. The condition comes on gradually, but in some cases the first thing the patient notices is the acute pain, and this lends some erroneous support to the diagnosis of a torn muscle, a nipped synovial membrane, or a displaced orbicular ligament. On examination the pain can be elicited either passively, as when the surgeon presses with his thumb immediately above the external condyle of the humerus, or actively, by asking the patient to grasp something firmly with the hand of the affected side, when the pain will at once be experienced in the same situation as before. When performing the passive method it is as well to be ready with some smooth-worded apology, such as "Ah, I was afraid that might hurt you."

It is, of course, possible that such injuries as a torn muscle and a displaced orbicular ligament do occur, but they do not constitute a "tennis elbow," and should not be diagnosed as anything but what they are.

Now for etiology. I have been called upon to treat a considerable number of these cases, but was surprised to come across identical troubles among people who had never played tennis. A few examples will suffice.

1. A civil servant who had been sawing up a tree which had been felled in his garden.
2. A Metropolitan policeman who had been indulging in what, to him, was the unusual pastime of towing a boat.
3. A boilermaker who had been on a particularly heavy job of rivet-cutting.
4. A lady who had been using a small hand tool for weeding a treasured patch of grass.
5. A golfer who was attempting to recover from a bad attack of "socketing" by an intensive course of mashie practice.

These are very diverse forms of exercise, and I looked for the common factor and decided that it was the *prolonged act of grasping*. This I advance as the true cause of tennis elbow, and I am supported by the fact that it is this very act which elicits the pain when the condition is established. When one thinks of it, there are not many games or trades which call for the prolonged act of grasping. At cricket and golf the grip is only momentary, and is separated by intervals when the bat or club is merely held, not gripped. Rowing does not call for a prolonged grasp, though novices (such as the policeman mentioned) do not realize this. A glimmering as to the real cause of tennis elbow has occurred to those coaches who attribute it to having a racket with too large a handle, for a thick handle puts more strain on the grasping powers than does a smaller one. I am prepared to predict that a tennis elbow will be found in any trade or game which calls for the prolonged grasping of an implement of any sort, and I did actually predict the possibility of this complaint in the lady whom I found weeding, and incidentally I got no thanks for my attempts in preventive medicine when, later on, I was able to say, "I told you so." It is possible that some forms of writers' cramp are due to prolonged grasping of the pen.

The pathology of tennis elbow is not so easy. The pain is certainly due to an affection of the extensor group of muscles, especially at their insertion into the ridge running from the outer condyle of the humerus. I may note in passing that it is, of course, the flexors which perform the grip, and that the extensors are merely engaged in synergic opposition. It may be that some anatomical oversight has left these muscles with a poor blood supply at their insertion, and that when they are overworked they suffer from an ischaemia. If persisted in this would be followed by oedema and local myositis, and would suffice to account for both forms of pain—the dull ache being due to the myositis and the acute pain to the spasm on contraction.

As regards treatment, I have found massage useless, even harmful at times, and, if my suggestions on the pathology are accepted, this is not to be wondered at; one might as well advise massage for a gum-boil. Usually the first advice is rest. This is always unsatisfactory to the patient, who invariably has a tournament next week which "I simply must go in for." No wonder that our unorthodox opponents dispense with this advice and fall back on diathermy. In my experience it is the most useful treatment. The heating up of the muscle eases pain, relieves tension, and improves the circulation and absorption of exudates. Galvanization is also useful, but is slower in action. Manipulation of the joint has its uses. This might be wondered at if, as is suggested, there are no tears or displacements in tennis elbow. But I think the stretching of the muscle does relieve the subacute spasm and oedema, and possibly serves to break down some inter-fibre adhesions within the muscle sheaths. Should treatment on these lines be unduly delayed it is well to search for some such cause of trauma persistence as defective teeth and other sources of toxaemia.—I am, etc.,

H.M.S. *Benbow*, Plymouth, Dec. 16th. W. H. EDGAR, M.D., Surgeon Commander R.N.

CHILD GUIDANCE CLINICS.

SIR,—The recent movement to institute special clinics for difficult or delinquent or otherwise unstable children is one of considerable importance, both from the social aspect and for the prevention of mental disease. It is very desirable that such clinics should be associated with general hospitals and that the medical profession as a whole should be interested in the movement.

General hospitals, with their equipment both for medical investigation and through the almoner's office for social inquiry and aid, are particularly fitted to house such clinics, and to see that they maintain a certain standard. One regrets, therefore, the comparative indifference of general hospitals to the movement, with the result that most such clinics are being set up independently. The indifference of the majority of the medical profession to the problem is also encouraging "educationists" to claim that they are the rightful persons to run such clinics. On the contrary, the aim should be one of co-ordination between medical and educational workers. The list of complaints for which children seek advice at such clinics suggests very strongly that the investigation must primarily be a medical psychological one. The scholastic maladaptation, upon the frequency of which certain educationists stake their claim to a monopoly of interest in these children, is simply an indication as a rule of a wider instability. More localized inadequacies exist, such as difficulty in learning to read, an examination of which without a medical bias might readily lead to the missing of important defects, or to faulty evaluation. But we cannot in the profession claim to staff these clinics either in a directory or advisory capacity unless we train recruits for the work from the ranks of the younger graduates, and it is difficult to see how this is to be done adequately unless general hospitals take a livelier interest in the whole movement.—I am, etc.,

London, W.1, Dec. 10th. R. D. GILLESPIE.

BLOOD AND URINE IN ASTHMA.

SIR,—Clinical biochemists will emphatically endorse Dr. Hurst's view, expressed in his paper to the Section of Medicine at the Annual Meeting of the British Medical Association at Manchester, and published in the *British Medical Journal* of November 9th (p. 839), that mild deviations from the normal chemical composition of the blood and urine, "though compatible with perfect health, form the basis of the congenital and often inherited constitutional tendency to develop certain diseases." General acceptance of this view will not only lead to more efficient treatment

of patients suffering from asthma, but open up a large field for the application of preventive measures.

During the past few years I have had many opportunities of investigating families whose members have shown a tendency to asthma or related conditions, and have formed the conclusion that to produce the complete syndrome the following three factors are required: a basic toxic condition, an ethmoid implication, and an irritable nervous system. My investigations have shown that the body fluids of asthmatics, in their chemical composition, differ more than slightly from those of the average person, and that the same combination of abnormalities, with variation in degree, presents itself in every case. In reply to the question, "What is the physiological normal?" it may be said that sufficient work has been done to establish a normal range of figures for the chemical composition of the blood and urine in health, and clinical significance may all the more readily be attached to deviations from these norms if, as in such a syndrome as asthma, all cases show a constant deviation in the same direction. The blood and urine obtained between attacks differ from those during an attack, but it is more important to know the chemical composition of the former—namely, the basic composition representing the individual's "normal"—than of the latter.

In the blood of every case of asthma I investigated I found the following changes: (1) lowered alkali reserve, figures down to 40 per cent. being common; (2) reduced calcium; (3) reduced P_2O_5; (4) except in early cases a lowered resting in sugar; (5) diminished suspension stability of corpuscles; (6) urea content at about the lower range of normal figures; and (7) raised bilirubin, uric acid, sodium chloride, amino-nitrogen, and refractive index of serum. The one variation was in the cholesterol content; it seemed to vary with the resisting power of the individual. Only in advanced cases was it reduced, 0.09 being the lowest figure recorded; in all others it was above, often greatly above, normal. I believe the increase of cholesterol is an effort of the body to counteract the acidosis—in other words, to keep the *p*H of the blood at or near normal. In my series I found, as Barber and Oriel (*Lancet*, vol. ii, 1928, p. 1009) have found in theirs, that the blood amino-nitrogen was always raised, and that it rose still further immediately before and during an attack, after which it fell gradually to its original level. They also describe a chloride shift, but I was not able to verify this finding; no fall in blood chlorides appeared simultaneously with the rise in amino-nitrogen. The blood sugar tolerance curve could be correlated with the patient's clinical condition. In moderately severe cases of long standing there was a low resting sugar with a flatter than normal curve; the sugar content returned to its original figure at the end of ninety minutes.

Investigating the urine of asthmatics I have collected twenty-four-hour specimens and found that, in general, the specific gravity is high, and, as Barber and Oriel have noted, that urate deposits are present even when the specific gravity is low. The other findings include high figures for acid (free and/or combined), disturbed acid ratio, and a high sulphate, chloride, uric acid, and protein content. Creatinine was found frequently raised, more particularly in one or two of the specimens. One other interesting feature in the urine is the high amino-nitrogen, the highest readings being obtained in the urine passed in the early morning hours, the period during which bronchial spasm occurs most frequently. I have tested, as a routine, for Barber and Oriel's ether reaction in the urine, but in no case of asthma have I found it positive.

I agree completely with Dr. Hurst's view that skin tests and desensitization are of limited practical value; the allergic phenomena are found only in about half the number of cases, and desensitization methods are bound to be disappointing, for they deal with a condition secondary to the basic toxicosis. After detoxication patients can live with their old enemies with impunity, a result I have never known to follow desensitization. Following Mr. McDonagh's methods I have regularly observed the protein particle picture which he describes. Here, again, there are differences between bloods taken during and between attacks: in blood taken during an attack hardly a single particle is seen: all are in precipitated sheets made up of very refractile particles. I assume that this is the hydrated blood with precipito-hydration at the attack. Strangely enough, in the only case of asthma I had where the spasm was only very slight the urine findings were typical, but the blood chemistry and protein picture resembled McDonagh's description of dehydration. This fact corroborates his claim of dehydration passing on to hydration.

I believe that the toxic agent acts on the protein particles of the cell just as it does on the protein particles of the blood, and agree with Mr. McDonagh that a toxicosis is the primary cause of asthma, as it is of all disorders. To complete the asthma syndrome, however, there must be implication of the nasal and ethmoid areas.—I am, etc.,

Northampton, Dec 14th. A. J. D. CAMERON, M.B., Ch.B.

SANITATION ON THE RIVIERA.

SIR,—At this time of the year a large number of British people are making up their minds where to go for the winter. Many are bound for the Riviera, and a regular campaign is being opened in the press to encourage them to do so. Having spent last winter there I made certain observations, which I think may be of interest to some of your readers.

Nice, where I spent three months, is a town of nearly 156,000 inhabitants, which receives during the winter season about 100,000 foreign guests, but it empties its sewage on its foreshore. Such a condition of things appeared to me absolutely impossible of belief, and I therefore was very careful in confirming the correctness of the above statement, which I believe to be beyond all dispute. The Nice shore, during the season, is crowded with visitors bathing, sun-bathing, and otherwise enjoying themselves. Along the foreshore are a number of very popular and much-frequented cafés. Numbers of people sit in and around these cafés and bathe from the shore. An open sewer not only flows out alongside of one of them, but as the tide goes out its stream actually washes the pillars of the café. On a still, warm evening a doctor friend and myself were obliged to make detours at intervals to avoid the sickening smell that comes up from these streams, which are dotted along the Nice shore and flow under the Promenade des Anglais to enter the sea across a stretch of pebbly beach. Nothing but the wonderful sun of the Riviera would permit of the possibility of such a condition of things. My doctor friend tells me that a friend of his had tried bathing and had given it up on ocular evidence of the disgusting nature of these streams. On inquiring among responsible people in Nice I was informed that the authorities had never faced the expense involved in putting matters on a proper basis.

Another point in the same connexion. The rubbish carts tip their contents over the rocks into the sea. I have seen this happening between Nice and Monte Carlo, and am told it happens all along the coast. Such a practice is indefensible. I submit that if Nice is to continue to grow and to invite and receive 100,000 or more people from every part of Europe, those people have the right to claim such expenditure of money as shall ensure a hygienic state of affairs.—I am, etc.,

R. H. ELLIOT,
London, W.1, Dec. 17th. Lieutenant-Colonel I.M.S. (ret.)

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

SIR,—I had hesitated to reply further to the letters by Dr. Monckton Copeman and Dr. Gouldesbrough on the above subject, but as it has been represented to me that silence might be misconstrued, I wish to make a brief statement concluding the discussion on my side.

Corneal ulcers afford a ready test of the value or otherwise of adding fluorescein secondary radiations to ultra-violet or *x*- or gamma-radiation. Surely Dr. Copeman sees that to establish his claims he must prove that fluorescein so intensifies the effect of radiation that its use is a clinical advance. If, however, an ophthalmologist like Birch-Hirschfeld finds its use uncertain and of doubtful value, this fact has some bearing on Dr. Copeman's claims. Perhaps he will induce dermatologists to test the value of fluorescein in the *x*-ray treatment of such conditions as

eczema, psoriasis, or acne, and then, if it proves of value, it might legitimately be tested in the more complicated sphere of cancer therapy.

Dr. Gouldesbrough does not like "theoretical" criticism: but surely he appreciates that Hollhusen's experimental finding that secondary radiations do not even penetrate effectively the chitin envelope of ascaris eggs strongly supports my suggestion that the painting of the skin over a tumour is more a magical than a scientific procedure, where the effect of a physical sensitizer is in question. He says he regards the "pastille dose" as equivalent to the "erythema dose." About twenty years ago Albers-Schönberg showed that these doses are equivalent only for medium-soft unfiltered rays; for harder unfiltered rays and filtered rays there is a scale of variation—for example, for 1 mm. aluminium filter the erythema dose is 1⅔, and for 3 mm. 2¾ pastilles (half-distance pastille scale), or ⅔ if the pastille is placed on the skin. Therefore if the statement (August 10th, p. 235) that the dose given was "a three-quarter Sabouraud B pastille (placed on the skin)" (4 mm. filter) be read a three-quarter "erythema" dose, we arrive at his dosage—not quite the full erythema doses I thought were being given to ulcerated surfaces, but, repeated for months in three weekly series, much more than "a comparatively small dosage" (p. 233).

Mr. C. H. S. Webb's patient had a primary ulcerated breast; treatment was abandoned owing to multiple secondary growths.

Dr. Gouldesbrough's contemptuous reference to "the old method of so-called 'deep therapy'" may, I hope, not count for much. Why "old," and why not "deep"? It would be just as illuminating to say that a surgeon had treated a patient by "the old method of a so-called 'deep incision'"! Like other methods of medical treatment, radiotherapy has so much to work and hope for that it must be surely a matter for regret when its main line of advance is side-tracked—as appears to be happening in the present instance.—I am, etc.,

London, W.1, Dec. 14th. J. H. DOUGLAS WEBSTER.

TREATMENT OF GASTRIC AND DUODENAL ULCER.

SIR,—With reference to Mr. Cahill's letter in the *Journal* of December 14th regarding the difficulty he finds in persuading patients to continue the duodenal tube treatment, I cannot say that this has been my experience.

During the past two years, at St. Mary Abbots Hospital in Kensington, I have treated some twenty-five cases by this method, and have invariably found that the few who have refused have done so either during the actual passing of the tube or within the first twenty-four hours. Once treatment has been established no patient has been unwilling to carry through the complete course.

One of the most striking features in the treatment is the manner in which pain ceases within twenty-four hours of the passing of the tube. This can be definitely promised, and if at the same time the rationale of the method is fully explained to the patients it goes a very long way towards satisfying them as to the value of undergoing the treatment.

I should like to add that in the series referred to I have had only one failure.—I am, etc.,

London, W.8, Dec. 13th. J. OWEN REID.

SIR,—I am unable to give Mr. F. K. Cahill (December 14th, p. 1134) any direct information about the difficulty of getting patients to submit to duodenal tube feeding for a period as long as eighteen days, but during my stay in a nursing home there were three other patients undergoing similar treatment, without, so far as I was aware, any serious complaint. After the first twenty-four hours it is surprising how little real inconvenience the retention of the tube causes; with the tube looped round one ear, the daily bath and the society and conversation of friends can be indulged in without discomfort. It is essential that whoever is in charge of a case should thoroughly understand the details of the feeding and the cleansing of the tube, so patients should either go into a nursing home or procure a nurse with some experience in similar cases. I find no difficulty in swallowing the tube and passing it through the pylorus within fifteen minutes. If practitioners, by personal experiment, would convince themselves of the simplicity of the procedure, they would then be in a position to allay any misgivings on the part of their patients—even to give them a practical demonstration.—I am, etc.,

Bratton, Dec. 15th. T. WOOD LOCKET.

THE ACETIC ANHYDRIDE TEST IN CEREBRO-SPINAL FLUID.

SIR,—With reference to Dr. Grossman's criticism (December 7th, p. 1084) of Dr. Herbert's article on the "Boltz test" (November 23rd, p. 953), I should like to state that I investigated this test in 1925, and my results agree exactly with those of Dr. Herbert. The colour is produced by the tryptophane constituent of proteins. I found that if a solution of protein—for example, blood serum—was made of the same concentration as that of the cerebro-spinal fluid tested, the colour produced in the two cases was exactly the same. Dr. Grossman states that "the coloration is due most probably to the presence of cholesterin." I can find no evidence whatever of this.—I am, etc.,

London, Dec. 17th. BARBARA M. WILKINSON, M.B., B.S.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

RECEIVING, on December 16th, a deputation which advocated reforms in the lunacy laws, Mr. Greenwood, Minister of Health, said that he could not agree to modification of Clause 5 of the Mental Treatment Bill—that dealing with treatment without certification of persons temporarily incapable of volition. If the House of Lords were to delete that clause he would not bring forward the bill in the House of Commons.

At the invitation of Mr. Somerville Hastings a meeting of medical practitioners, including six medical members of Parliament, was held at the House of Commons, on December 12th, to revive the National Medical Services Association, which had been practically in abeyance during and since the war. This body is intended to replace the State Medical Services Association, and will be confined for the present to members of the medical and dental professions, with a few invited persons who are specially interested in the movement to nationalize all medical service. Dr. Ethel Walker was appointed temporary secretary, and a provisional committee of eight was set up, which was to meet on December 19th. The inaugural meeting of the association is reported to have been attended by supporters of all political parties. The committee met on December 19th for the purpose of drafting a constitution for the organization.

Mr. Remer gave notice to introduce in the House of Commons, on December 17th, a Nurses Registration Act Amendment Bill, to enable nurses possessing the Royal Medico-Psychological Association's certificate to be certified as mental nurses. The bill has, however, been postponed till February.

On December 16th the Parliamentary Medical Committee met at the House of Commons. It discussed deafness and the action of the National Institute for the Deaf in advocating inquiry by the Ministry of Health into the subject. The committee decided to ask the institute for a memorandum for discussion. It also decided to arrange visits to dairies. The committee's next meeting will be on January 28th, 1930.

The Conservative Health and Housing Committee met on December 18th, *Dr. Fremantle presiding in the absence of Mr.* Chamberlain, and decided to meet after the reassembly of Parliament to consider the Housing Bill, which the Government will probably then have presented.

The Home Secretary is understood to have completed the text of the Factories Bill, which may be presented before the House of Commons rises for Christmas, and printed soon after.

A non-party Science Committee has been formed among members of Parliament to further the interests of science and its application to politics.

On December 19th the Government's Coal Mines Bill was read a second time by 281 to 273. Despite the narrowness of the majority a dissolution of Parliament or change of Government is not anticipated.

Mental Treatment Bill.

REPORT STAGE IN THE LORDS.

In the House of Lords, on December 17th, the Mental Treatment Bill was considered on the report stage. On Clause 1, which gives power to receive voluntary boarders, Earl RUSSELL moved an amendment, which was agreed to, reducing the age at which persons could be received as voluntary boarders at the request of their parents or guardians from 18 to 16. Another amendment was agreed to omitting the word "unmarried," Earl Russell explaining that, with the reduction of the age those words were unnecessary, because now by law young people could not be married under 16. These amendments would meet objections raised during the committee stage.

Lord DANESFORT moved a new subsection to ensure that a young person should not be sent to an institution on a recommendation of a doctor which was old or out of date. It was, he said, founded on the analogy of Clause 5 (5), which made provision for putting a man into a place for mental treatment if he was incapable of volition. The recommendation of the doctor under Clause 1 of the bill had to state that the person was likely to benefit under treatment for mental disorder. That might be true at or very shortly after the time when the person was examined, but if the recommendation were used a month or two months after the examination, the statement might be quite untrue, because the patient might have recovered, and, possibly, no longer be likely to benefit by being put in a place for mental treatment. Therefore his proposal was that the medical recommendation should cease to have effect at the expiration of fourteen days from the last date of examination.

Earl RUSSELL said that the amendment was perfectly proper. The object was to avoid a stale recommendation. He would accept the amendment if it could be moved in the following form:

(4) "The medical recommendation shall cease to have effect for the purposes of this section on the expiration of fourteen days from the last date on which the person to whom the recommendation relates was examined by the medical practitioner for the purposes of making the recommendation."

Lord DANESFORT agreed, and the amendment was carried.

A drafting amendment, moved by Earl RUSSELL, to omit the words "superintendent or other person in charge, or to the person with whom he is residing in single care," and to substitute "person in charge," was agreed to.

Clause 2 deals with notice of reception, death, and departure of voluntary boarders, and makes provisions as to boarders who become incapable of volition. On Earl RUSSELL'S motion a new subsection (4) was agreed to, providing that if a voluntary boarder under 16 ceased to have any parent or guardian, or if his parents or guardians were incapable of performing, or refused or persistently neglected to perform their duty as such, the person in charge should report the circumstances of the case to the Board of Control and the condition of the boarder, and the Board should consider the report and give such directions as it thought fit.

Clause 5 makes provision for treatment without certification of persons temporarily incapable of volition. Earl RUSSELL moved to amend Subsection (3) so as to provide that an application should be accompanied by a recommendation signed by two registered medical practitioners, of whom one should be a medical practitioner (not being the usual medical attendant of the person to whom the application related) approved by the Board of Control for the purpose of making recommendations under this section, and the other should be, if practicable, the usual medical attendant of the person to whom the application related.

The Earl of ONSLOW observed that the original drafting of the bill said that it should be the family doctor, or, if not, then a person approved by the Board. In the event of there being no family doctor, would two doctors be approved by the Board? Earl RUSSELL said that the clause would read that it should be a medical practitioner approved by the Board and, if practicable, a family doctor. If there was no family doctor it would be any doctor that could be obtained.

Lord MERRIVALE said that Earl Russell was justified in what he was doing. He had been very much surprised on the previous day, among various communications from medical men, to receive one from a medical man with, he supposed, as large a private practice as there was in relation to matters of unsound mind and defective mentality, endorsing the insistence that there should be some additional safeguard. He hoped that this additional safeguard would be agreed to. The amendment was agreed to.

On Earl RUSSELL'S motion another new subsection (12) was agreed to as follows: "A person received as a temporary patient shall not be detained as such for more than twenty-eight days after the date at which he regains volition unless in the meantime he again becomes incapable of volition." He explained that this gave effect to Lord Cranbrook's proposal that a temporary patient should be discharged twenty-eight days after recovering volition unless he relapsed in the meantime. The effect would be to give him more avenues of discharge than any other patient.

A long debate took place on Clause 15, which gives power to make rules. Earl RUSSELL moved in a different form a new subsection which had been accepted in committee, providing that rules made, under Section 338 of the principal Act, after January 1st, 1931, should be laid before both Houses of Parliament, and if within twenty-one days an address should be presented to His Majesty by either House praying that a rule should be annulled it should be void. On Viscount BRENTFORD'S suggestion the date of January 1st, 1931, was omitted, the noble lord pointing out that power to make rules began long before the Act otherwise came into operation. Viscount Brentford then moved a further amendment to the new subsection, providing that the rules which not only the Minister of Health but, under other clauses, the Board of Control, were empowered to make, should not come into force where they modified or adapted this measure or any other enactment until the rule had been approved by each House of Parliament. He urged that if there was to be any change made in this legislation it should be done only by Parliament. In the subsection power was given to the department to make rules which would alter this bill. Earl RUSSELL pointed out that the rule-making power which the subsection proposed would not enable them to alter the bill. The rules, apart from the administrative rules, which would not come under Viscount Brentford's amendment, would not make new laws. They would be the most trifling adaptations of an old Act to new circumstances, and would in no sense alter anything that Parliament had agreed to. He hoped the House would not insist on the amendment. After further discussion, Earl Russell suggested that the matter should stand over till the third reading for further consideration and consultation. The House, however, accepted Viscount Brentford's amendment, and also the subsection as thus amended.

The report stage was concluded.

Highlands and Islands (Medical Service) Additional Grant Bill.

Mr. ADAMSON (Secretary of State for Scotland) expounded the Highlands and Islands (Medical Service) Additional Grant Bill to the Scottish Standing Committee of the House of Commons on December 3rd. He recalled that the Highlands and Islands Medical Board, instituted in 1913, had been superseded in 1919 by the Scottish Board of Health, and that again, in 1928, by the present Department, which administered the fund for medical services and nursing in Argyll, Caithness, Inverness, Ross and Sutherland, and the Highland districts of Perthshire, covering half the area of Scotland. At present about £43,000 per annum was spent on the services. The poor economic condition of the people precluded adequate payment to medical practitioners, and grants were paid to the doctors on condition of their charging uniform fees, regardless of the distance to be travelled. This service was available to the uninsured cottar and crofter classes, but not to private patients able to pay ordinary fees. Further additions to the medical staff were still necessary, though the guarantee of a reasonable income had attracted to the Highlands a better type of medical practitioner than was previously available. In 1913 over 10 per cent. of the deaths in the Highlands and Islands area were uncertified. In 1928 this had been reduced to 5 per cent., which was still greatly in excess of the figure for other parts. There had also been an improvement in the nursing services. Subsidies were paid to 72 nursing associations, maintaining 174 nurses, but there was still much need for development of this nursing service, on which at present £14,000 per annum was being paid in subsidies. Nothing had yet been done in the area towards the establishment of such services as dentistry. A beginning had been made towards the provision of hospital and surgical services, and in three hospitals it had been found possible to appoint whole-time surgeons. Many other areas, particularly in the Islands, required small cottage hospitals, to avoid sea journeys for the patients. In March, 1920, owing to the war, the Fund had a large unexpended balance, but in March last this had decreased to £7,000, and further provision must now be made to meet the developing needs of the service. This year it was estimated to cost nearly £70,000. The original annual grant of £42,000 had been determined on vague and incomplete data, and must be supplemented. The present bill would not set aside a fixed annual amount, but must take into account reasonable development and authorize such additional sums as might be voted annually by Parliament. In the present year the additional money required would be just over £10,000; in future years between £20,000 and £30,000.

Dr. ELLIOT said Mr. Adamson's statement met with approval from Conservative members for Scotland. He himself had said, when in office, that no party would hesitate in making ample provision for this fund. He pointed out that the additional grant would not be non-recoverible by the Treasury, and that the Estimates for it would be scrutinized by that Department, which would recover any unexpended balance. Dr. Elliot agreed that nursing and dental services should be expanded in the Highlands, and nurses should be supplied with light cars instead of pedal cycles or motor cycles. He mentioned that he had investigated

the possibility of moving hospital patients from Lewis by aeroplane, but he had found that the provision of such a service would cost £10,000 per annum, and that increased provision of cottage hospitals was preferable. The provision of adequate medical and social services would prevent rural depopulation. In France the Government was acting on that theory.

Mr. MACQUISTEN thought that in an island like Islay it should be possible, not to provide a hospital, but to arrange that one of the doctors should have surgical experience, and could undertake emergency operations.

Mr. JOHNSTON (Under-Secretary of State) said this was one of the matters which would receive attention as the bill passed.

In regard to dentistry, Mr. MACQUISTEN said the late Dr. Donald Murray had told him that fifty years ago every youth of 17 in Stornoway had a sound set of teeth, whereas now it was impossible to find one whose teeth were not decayed. That was due to a change of dietary.

Mr. ROBSON said that houses in parts of the Western Isles only had access by miles of narrow footpaths, impassable even for a bicycle. More roads were required, and a telephone in every school of the Islands for emergency calls.

Mr. R. W. SMITH said that districts outside the area covered by the present bill had needs as great. In parts of Aberdeenshire the population was as scattered as in Inverness.

Mr. JOHNSTON said the Highland district of Aberdeenshire already received a Necessitous Areas grant. Since 1924 that had been provided under the National Health Insurance Act, and it might be increased, though not under the present bill.

Sir ROBERT HAMILTON said great success had attended the appointment of consultative surgeons to the small hospitals in the North. Orkney and Shetland each now had a consultative surgeon. The result, however, was that the hospitals at Lerwick and Kirkwall were filled with surgical cases, which in past years would have gone to Aberdeen or Edinburgh. More beds were required, in consequence, for medical cases and for the staffs. He asked the Secretary of State to help with the capital expenditure.

Major DENDSON said that Galloway, in southern Scotland, also required aid in provision of medical services. They had widely scattered areas with no roads, where the maintenance, in particular of nursing services, was difficult.

The Duchess of ATHOLL said she had been a member of the Dewar Committee which recommended the original grant to the Highlands. She retained an indelible impression of the sickness and death which could have been avoided if the medical and nursing services were more adequate. The original grant of £12,000 had been based on an imperfect estimate, and she supported the proposed increase. She asked how many nurses were still needed for the Highlands and Islands area, and what was proposed in the improvement of the housing accommodation for them. Thirty-two houses had been built for doctors, but only some six for nurses.

Sir ARCHIBALD SINCLAIR said the bill merely proposed to bring the health services of the Highlands and Islands up to those in other parts of the country.

Mr. JOHNSTON said he was gratified to find the committee, without distinction of party, pressing on the Government a demand for a State medical service for Scotland. He would draw the attention of the Government to this fact.

The Duchess of ATHOLL pointed out that the grants were often made to supplement individual effort.

Mr. JOHNSTON, Occasionally, not generally. He said there was urgent need of considerable improvement in the Highlands and Islands Medical Services. At present there were only three hospitals in the area where surgical treatment could be given, and the Government intended soon to take steps to increase the number. The case of Islay would soon be considered. Dental services were also urgent. Some patients had to travel three days each way to get a tooth extracted. And for telephone expenditure had grown, and telephone facilities had been increased this year in the Highlands. The Highland districts of Aberdeenshire and other areas excluded from the bill got £32,000 mileage grant from the Health Insurance Fund, and other allowances for provision of additional medical assistance, and these might be extended. These grants did not reach the areas scheduled in the bill. He was informed that about fifty additional nurses were required in the scheduled area, and houses would be provided.

The bill was then reported to the House without amendment.

Subsequently the bill passed through third reading in the House of Commons, and was sent to the House of Lords, where it was read a second time without discussion on December 16th, and passed through committee without amendment on December 17th.

In committee of the House of Commons, on December 16th, a supplementary estimate of £10,650 for the Scottish Department of Health, including grants in aid of the Highlands and Islands Medical Services, was agreed to. The resolution was considered on report on December 17th. Dr. ELLIOT said that this was a matter of urgency, and they all desired that it should go through. It was, however, most undesirable to take a supplementary estimate after 11 o'clock at night, when the House had no opportunity of review. Mr. JOHNSTON said that the bill which was now passing through the House of Lords was an agreed one. It was common ground that this money must be got if the doctors and nurses engaged in the Highlands and Islands Medical Services were to get their salaries. The supplementary estimate was agreed to.

The bill was read a third time, without debate, in the House of Lords on December 18th.

Position of Medical Officers of Local Authorities.

On December 12th Mr. Greenwood promised to furnish Dr. Vernon Davies with a memorandum on the position of medical officers of local authorities. This memorandum has now been officially communicated. It states that where a person who is now an official of some other local authority, and is a county councillor or a councillor of a borough, is transferred by the Local Government Act, 1929, to the service of the county council or the town council, as the case may be, he will, when the transfer takes effect, be automatically disqualified, by pre-existing Acts, from membership of the council which has become his employer. The memorandum proceeds:

The practical application of the law may be briefly set out thus:

1. A medical practitioner who holds a salaried appointment under a local authority cannot be a member of that authority.

2. A medical practitioner having a contract for occasional service (for instance, one who attends at a maternity and child welfare centre and is remunerated by specified fees) is similarly disqualified, as having a contract with the local authority.

3. There are some statutory provisions under which, for example, a medical practitioner is entitled to fees on his sending to the local authority a certificate concerning one of his patients or on his attending a confinement on demand by a midwife. Parliament has provided that the sending of a certificate in case of infectious disease shall not disqualify, and the Minister has been advised, similarly, that a medical practitioner who is called by a midwife and receives a fee under the Midwives Act, 1918, is not disqualified; he does not receive his fee in pursuance of a contract with the local authority, but in virtue of the statutory obligation imposed on them to pay his fee.

You will have noticed that the report of the Royal Commission recommends that there should be no change as regards salaried officials, but they apparently contemplate that the second class above mentioned shall be put in the same position as the third.

A fourth class of case, which is not expressly dealt with by the Royal Commission, is that in which a local authority makes payments to a hospital and the physician or surgeon working at the hospital receives a part of the payment. Whether disqualification ensues or not seems to depend here upon the particular facts—for example, whether the amount of the fees received by the medical practitioner is affected by the terms of the contract between the hospital and the local authority, so that he has an "interest" in that contract.

The memorandum remarks: In any legislation based on the report of the Royal Commission these cases will clearly have to be considered, but Mr. Greenwood does not wish to commit himself to particular proposals until there has been fuller opportunity for thinking out the problem.

Small-pox in Glasgow and Aberdeen.—Answering Mr. Freeman, on December 17th, Mr. JOHNSTON said that 17 cases of small-pox in Glasgow and one case in Aberdeen had been traced to the infection on the steamship *Tuscania*. Mr. Johnston circulated a table showing the vaccinal condition of those cases. According to this table, 15 of the cases had been successfully vaccinated in infancy, and a certain number of those revaccinated, with negative results.

Maternity and Child Welfare Centres in Uganda.—Dr. SHIELS, replying on December 16th to the Duchess of Atholl, said that in 1928 there were 56 district sub-dispensaries in Uganda, 24 native hospitals at which dispensary treatment could be obtained, and 41 maternity centres. Four new maternity centres were in course of construction. There were 93 native midwives on the official midwives' roll of Uganda on January 1st, 1929. The Protectorate Government contributed annual grants to missions for the maintenance of midwifery centres and midwives. Steps had already been taken in Kenya for the provision of trained midwives by the Government and by voluntary effort. At the end of 1928 child welfare clinics were in operation in Nairobi, Mombasa, and Kisumu, and additional centres were to be opened in Mombasa this year. The Lady Grigg Child Welfare League had maternity homes and child welfare centres in Nairobi and Mombasa. Training in midwifery of Indian and native women was undertaken at these centres.

Antimalaria Measures at Singapore.—On December 11th Mr. ALEXANDER said, in reply to Colonel Howard-Bury, that the decision to suspend further work on the naval base at Singapore would not involve the closing down of the antimalaria measures now being undertaken in the neighbourhood of the base. The cost of the antimalaria work was borne by navy votes.

Health Services in Equatorial Africa.—Replying to the Duchess of Atholl, on December 11th, Dr. SHIELS said the total Government expenditure on health services, exclusive of capital expenditure,

was: for Tanganyika (1928–29) £232,467; for Uganda (1928) £141,713; for Kenya (1928) £199,198. Upkeep of hospitals, including expenditure on personnel, amounted to £16,015 for Tanganyika in 1928–29; £12,250 for Uganda in 1928; and £12,076 for Kenya in 1928. Construction and repair of hospitals, including expenditure on personnel, cost £14,974 in 1928–29 for Tanganyika, £2,254 in 1928 for Uganda, and £16,269 in 1928 for Kenya.

Pre-marriage Rites Practised by African Native Tribes.—On December 11th Dr. DRUMMOND SHIELS told the Duchess of Atholl that mutilating pre-marriage initiation rites were still practised on young girls among many African tribes. Considerable caution was necessary in interfering with native customs, but colonial Governments had brought persuasion to bear upon tribes which practised the rite in its more brutal forms, and a number of local native councils in East Africa had passed resolutions making illegal the severer forms of the operation. Later, on the same day, a debate arose on British colonial policy towards native races, and the Duchess of ATHOLL again referred to the circumcision of young girls in Africa. She said this was practised in Southern Nigeria, in one Uganda tribe, and in its worst form among the Kikiku in Uganda. Medical men stated that this rite consisted of the removal of whole sets of parts connected with the organs of reproduction, performed publicly by an old woman with an iron knife. No anaesthetic was given, and no antiseptics were used. The old woman went from one girl to another, turning the knife once or twice in each victim. The operation was followed by much scarring and great contraction. Blood poisoning occurred, with the result that there was great suffering at childbirth, and the first child was seldom born alive. A medical man of standing in East Africa had stated that, while there was a lesser, and less severe, form of mutilation, he would not sanction even that by anyone under his control. The Duchess commented on the scarcity of midwives and women nurses in Kenya. In Uganda, which had twenty-six centres for maternity and child welfare, the infant mortality had dropped in ten years from 500 per 1,000 to 150. Dr. DRUMMOND SHIELS said there was difficulty in interfering with traditional customs, and considerable effort would be required to stop the rite mentioned by the Duchess of Atholl. The Secretary for the Colonies (Lord Passfield) was getting all available information, in the light of which he might be able to take action which would satisfy the conscience of the House of Commons.

Treatment of Pensioners in receipt of Final Award.—On December 16th Mr. F. O. ROBERTS told Mr. Longden that it was open to any pensioner in receipt of a final award to apply for treatment for a condition due to war service. If, as a result of such treatment, the award was found to have been seriously erroneous as an assessment for permanent purposes, a further grant could be made.

National Radium Fund.—In the House of Commons, on December 18th, when the Consolidated Fund (No. 1) Bill was read the second time, Sir KINGSLEY WOOD asked for information on the administration of the National Radium Fund. After referring to the success of the Fund and the generosity of the subscribers, he urged that efforts should be made to extend the field of supply of radium. Empire resources should be developed, and particular attention directed to the possibility of obtaining supplies from Cornwall. Miss LAWRENCE said that, as the Radium Commission was appointed by Royal Charter, the Ministry of Health was not responsible for its work. The Commission would in due course present its annual statement and accounts.

Notes in Brief.

In Mr. F. O. Roberts's opinion the machinery of formal appeal to an appeal tribunal is not the most suitable or most expeditious mode of determining such purely medical matters as the form of treatment appropriate to a particular case, where there is a difference of opinion between the man's own doctor and the Ministry's medical adviser. Mr. Roberts has arranged that any difficult cases, where representations are made by panel doctors, are reviewed at the headquarters of the Ministry.

On December 17th Sir C. Trevelyan presented a bill to raise the school-leaving age to 15 years.

The amount paid into the National Health Insurance Fund during 1928 in contributions by employers and employees in England and Wales was £23,187,000.

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on December 17th the following medical degrees were conferred:

B.M.—C. M. Duncan, C. R. Salkeld, H. H. Aitchison, W. B. Fiddian-Green, J. L. Clapham, W. B. Williams, C. R. Greene, H. E. Mansell, J. A. Brown, Ruth Sandeman.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on December 19th the following medical degrees were conferred:

M.CHIR.—F. J. Milward.
M.B., B.CHIR.—L. J. Rae.
M.B.—L. R. Janes, C. G. Townsend.

UNIVERSITY OF LONDON.

MR. RONALD H. O. B. ROBINSON has been granted temporary recognition as a teacher of surgery and anatomy at St. Thomas's Hospital Medical School for the session 1929–30.

The dates for the examination for the academic Diploma in Public Health (Red Book, 1929–30, p. 439) will be as follows:

Part I of the examination will be held three times a year, beginning on the first Monday in April, or if that be a Bank Holiday, on the second Monday in April; the Monday of the week prior to the first Tuesday in July; and the fourth Monday in September.

Part II of the examination will be held twice a year, beginning on the Monday (or Tuesday, if such Monday be a Bank Holiday) in the week following that in which the April examination for Part I is held, and on the Tuesday in the week following that in which the September examination of Part I is held.

Examinations will commence on April 7th and June 24th, 1930, for fourteen medical entrance scholarships and exhibitions of the aggregate value of £1,340. They are tenable in the Faculty of Medical Sciences of University College and King's College and in the medical schools of King's College Hospital, University College Hospital, the London Hospital, and the London (Royal Free Hospital) School of Medicine for Women. The latest dates for the receipt of entries are March 12th for the April examination and June 10th for the June examination. Full particulars and entry forms may be obtained from Mr. S. C. Ranner, M.A., the Medical School, King's College Hospital, Denmark Hill, S.E.5.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

M.D.—K. M. Cobban, L. Earlam, R. R. Evans, J. F. Galloway, Mary S. Share-Jones.

M.CH.ORTH.—W. J. Eastwood, W. L. Macdonald, J. F. Shepherd.

FINAL M[illegible]
Part:
(1924
M. G
H. E. C. Sutton. Passed in separate subject: D. I. A. Williams (Public Health).

DIPLOMA IN TROPICAL MEDICINE.—S. D. Ahuja, R. E. Anderson, C. G. Booker, W. A. Bullen, E. N. Callum, P. P. D. Connolly, J. A. Cowan, [illegible]
A. T. Howell,
bloom, C. K.
H. N. Turner.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—‡Edith M. Booth, *F. N. Marshall, A. Allan, Hedley Boardman, R. O. Brooks, J. A. K. Brown, Christobel M. Hall, W. H. Harris, E. J. B. Sewell, Nellie Wilson. (*Part I, Forensic Medicine and Hygiene and Preventive Medicine*): G. M. Lendrum.

* Second-class honours.
‡ Distinction in forensic medicine.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Primary Fellowship Examination.

AT the primary examination for the Fellowship held in December 155 candidates presented themselves, of whom the following 49 were approved;

H. J. B. Atkins, D. A. Beattie, T. H. Berrill, D. D. Boovariwala, J. T. Chesterman, H. O. Clarke, [illegible]
K. K.
W. G.
Harihi
Kathai S. Kelkar, A. W. Kendall,
M. L. I wis, K. Lufnsden, J. Mark,
S. N. M. B. Morgan, H. F. Moseley,
W. Mushin, R. W. Nevin, T. H. Parkman, R. G. Pulvertaft, J. R. Ratcliffe, B. C. Rennie, V. C. Snell, H. H. Stewart, G. O. Tippett, A. G. Williams, H. M. Williams, B. Willinsky, D. S. P. Wilson.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

AT a meeting of [illegible] Edinburgh, held on December 18t President, was in the chair, the fol out of 70 entered, who passed the requisite examinations, were admitted Fellows:

F. Bekker, P. W. H. Bleasdale, J. B. Colquhoun, J. Comrie, C. Duncombe, A. M. Duthie, D. H. Fraser, C. A. Gardiner, W. J. Gill, A. L. Gunn, H. C. Gupta, J. Haslam, Elinor D. Jackson, L. H. Leggett, A. C. Liesching, V. M. Metivier, D. R. Paterson, J. E. Piercy, M. N. Sarkar, S. Singh, G. F. Skinner, O. J. Stahl, R. S. Verster.

SOCIETY OF APOTHECARIES OF LONDON.

THE Court of Assistants of the Society of Apothecaries has elected Lieut.-Colonel C. T. Samman, R.A.M.C.(ret.), as its representative on the General Medical Council for one year, in succession to Mr. Samuel Osborn, F.R.C.S., who has resigned.

Obituary.

JOHN SCOTT RIDDELL, C.B.E., M.V.O., LL.D., M.B., C.M.,

Consulting Surgeon, Royal Infirmary, Aberdeen.

As briefly announced in our last issue, Mr. J. Scott Riddell, the well-known Aberdeen surgeon, died on December 3rd, after a long illness.

John Scott Riddell was born in 1864, and received his medical education at the University of Aberdeen, where he graduated M.B., C.M., in 1888, after winning many honours, including the Keith gold medal in systematic and clinical surgery. For seven years he assisted the professor of surgery, delivering lectures on systematic and operative surgery, and taking charge of the practical class. He was also for a short time assistant pathologist to the Aberdeen Royal Infirmary, but resigned this post on becoming assistant surgeon in 1891. He was appointed surgeon and lecturer in clinical surgery in the Infirmary in 1893, and five years subsequently became senior surgeon; when he retired from this post in 1919, he was retained on the honorary staff in the capacity of consulting surgeon. In the same year he resigned from the clinical staff of the university, and was presented with an illuminated address by the medical students. He carried on an extensive practice as a consulting surgeon, being well known in this capacity throughout Scotland. He will, however, be specially remembered for his connexion with the Aberdeen Royal Infirmary, which lasted thirty-eight years. During the war, in addition to his duties there as surgeon, he undertook the responsibilities of medical superintendent. He was appointed a director in 1922, and was chairman of the board from 1924 to 1927, during which period the scheme for extension of this institution came into operation. Until the time of his death he was an assessor to the University Court.

MR. J. SCOTT RIDDELL.

Mr. Scott Riddell was particularly interested in ambulance work and was colonel in the Volunteer Medical Service Corps. Later he was appointed administrative medical officer for the Highland Division of the Territorial Force, and became a Knight of Grace of the Order of St. John of Jerusalem. He was one of the three medical officers of the Scottish Control Committee and Territorial Force Nursing Service. In 1908 King Edward conferred on him the membership of the Royal Victorian Order. During the war he undertook the duties of Red Cross Commissioner for the North-Eastern district of Scotland, and was made a Commander of the British Empire. The University conferred on him the honorary degree of LL.D. Always interested in athletics, he organized two cricket clubs in his student days. For a time he was president of the University Athletic Association, and he was an enthusiastic golfer. Mr. Scott Riddell published *A Manual of First Aid*, also *A Manual of Ambulance*, and a volume comprising the records of the Aberdeen Medico-Chirurgical Society, from 1789 to 1922. He was appointed deputy lieutenant to the City of Aberdeen in 1925. He associated himself actively with the work of the British Medical Association for several years, and was a member of the Aberdeen Branch Council in 1893 and 1900–4, honorary secretary of the Branch 1894–99, president in 1907, vice-president in 1908–9, and vice-chairman of the Division from 1909 to 1912. He was president of the Section of Surgery when the Association met in Aberdeen in 1914. (The photograph is by G. and W. Morgan, Aberdeen.)

DANIEL LEWIS THOMAS, M.R.C.S., L.R.C.P., D.P.H.,

Medical Officer of Health for Stepney.

THE London public health service, and the East End in particular, have suffered a grievous loss in the death, on December 10th, after a fortnight's illness, of Dr. Daniel Lewis Thomas, for many years medical officer of health for the metropolitan borough of Stepney.

Dr. Thomas qualified in 1893, and, intending a career in public health, took the D.P.H. in Ireland in 1896, and the equivalent diploma in England in the following year. In 1903 he became a member of the Bar. Before taking his post at Stepney he was one of the district medical officers of the London County Council. At Stepney Dr. Thomas had charge of one of the largest, most populous, and in some respects most difficult areas of public health administration in London. This East End borough has a population of a quarter of a million, compressed into less than three square miles, a population largely alien and seafaring. It says much for his energy and vigilance that the health record of Stepney stands so high; its death rate is actually below that of London as a whole.

Forbidding as his field of labour might have looked to others, the heart of "Dan" Thomas rejoiced in it, especially because at its very centre was the London Hospital. The London was his own medical school; he served there afterwards as demonstrator in public health; he was a familiar figure about the hospital day and night, and occupied the post of unofficial consultant on all matters of public health and epidemiology. During the war, in spite of many other duties, including that of food controller for the district, he took up his residence at the hospital in order to take all night calls and so allow the greatly depleted and almost exhausted staff to get unbroken nights' rest. His advice was always at the service of the London. Lord Knutsford relates how, on one occasion, when the house-surgeon on his night round was struck by the suspicious appearance of a case in the surgical ward, a telephone message to Dr. Thomas found him at a public dinner at the Connaught Rooms, and within twenty minutes he was at the hospital, where he confirmed the suspicion of small-pox, arranged for the patient's removal, and instructed the staff as to the measures to be taken for the safety of the other patients in the ward and their friends outside.

Dr. Thomas was a member of the Marylebone Division of the British Medical Association, and of the Society of Medical Officers of Health, also a Fellow of the Royal Institute of Public Health and the Royal Sanitary Institute. In one respect he was happy in the circumstance of his death, premature though it was, for it took place in the wards of the London Hospital, where he was cared for by the staff whom he had so greatly helped. His funeral took place on December 12th at Hammersmith, after a service at the Jewin Welsh Chapel.

DR. BRIAN MELLAND, whose death occurred at Bowdon, Cheshire, after a short illness, was a practitioner very much respected and esteemed by all who knew him. A son of Dr. Frederick Melland of Manchester, he was educated at the Manchester Grammar School and at Owens College. After graduating M.Sc.Viet. in 1886 and M.B.Lond. in 1888, he held resident appointments at the Manchester Royal Infirmary and the Children's Hospital, Pendlebury. In 1901 he proceeded to the M.D. degree.

In his younger days Melland was an all-round athlete, but was prevented from representing England at lacrosse by an attack of acute rheumatism. After a second attack of rheumatism he decided to go abroad, and for ten years he practised in Grand Canary. After his return to England he settled in Bowdon, joining the late Dr. W. Owen Jones in practice, and there he remained until his death. Dr. Melland was a member of the British Medical Association, and in 1902, when the Association held its Annual Meeting in Manchester, he was honorary secretary of the Section of Tropical Medicine. He published, in 1884, some original work on the histology of striped muscle, and in 1910, in an article in the *Lancet*, he introduced the now common method of treatment of an asthmatic attack by the injection of adrenaline. His account of Grand Canary, published in the *Medical Chronicle* in 1897, is one of the best. He was twice married, first to Florence Trevor Roper, and secondly to Kathleen Oliphant. His two sons were killed in the war, and he leaves a widow and five daughters.

Medico-Legal.

ALLEGED NEGLIGENCE IN CERTIFYING A MENTAL CASE.

ACTION AGAINST DOCTORS STAYED.

IN the Court of Appeal, on December 18th, judgement was given by Lords Justices Scrutton and Greer in an appeal by the defendants from a decision of Mr. Justice Finlay in chambers. This related to an action brought by Mrs. Jane Easton, of Lancaster Gate, London, against Dr. William Alexander Potts, of Edgbaston, a mental specialist, and Dr. A. V. Johnson, of Aldridge, Staffordshire. The plaintiff was certified by the defendants while she was on a visit in Staffordshire in 1926, and she brought the action claiming damages for alleged negligence on the part of the medical men. Mr. Justice Finlay refused to stay the action, and from this decision the doctors appealed.

Mr. H. C. Dickens, instructed by Messrs. Hempsons, appeared for the appellants, and Sir Henry Maddocks, K.C., and Mr. J. W. J. Cremlyn, instructed by Messrs. Coulson and Coulson, for the respondent.

In the result Lord Justice Scrutton announced, Lord Justice Greer concurring, that the appeal would be allowed and the action stayed.

Lord Justice Scrutton's Judgement.

Lord Justice Scrutton said that the case involved one of the most difficult jurisdictions that the court was ever called upon to exercise. While, on the one hand, it was of great importance to protect the liberty of the subject, on the other hand it was of equal importance to protect those persons who had been appointed by Parliament to exercise a duty in the interests of the community as well as of the patient. If any doctor certifying was to be exposed to the cost and danger of judgement by people who did not see the patient at the time, the natural effect would be that no doctor would certify, and the community would be exposed to the risk of having persons of unsound mind wandering about without adequate control, to their own danger, and possibly that of the community. It was common knowledge that the result of such actions had been that many doctors would not certify at all. Parliament itself had recognized, in Section 330 (2) of the Lunacy Act, 1890, that certifying doctors should have some protection against the risk of expensive, long-drawn-out, and harassing actions. They were open to actions based on charges of want of good faith or reasonable care, but Parliament had attempted to provide that an action should not go to trial except under certain special circumstances provided for in the subsection just quoted. The court, however, to grant a stay of action, must be satisfied that no reasonable jury could on the evidence find want of good faith or reasonable care.

Coming to the facts of the case, the Lord Justice said that it concerned a lady 48 or 50 years of age; possibly the age might have something to do with these events. The lady herself said that she was subject to malaria, and was suffering from a malarial attack at the time the certification took place. Her sister and another lady with whom she was staying were of opinion that she was of unsound mind. One of the first two doctors called in, however, thought that she was not in a condition to be certified. It had to be remembered that there were cases where a person might appear perfectly sane at one hour, and as perfectly insane at the next. The Lord Justice recalled a case he had tried at Exeter, where a man was accused of attempting to murder an asylum attendant. The man conducted his own defence perfectly correctly, and behaved himself as an exemplary witness but suddenly an irrelevant remark let loose his delusion—that he was a member of the royal family, with special rights for dealing with anybody of whom he disapproved. In the present case a second doctor, Dr. Potts, a Birmingham mental specialist, saw the lady next day, and on his certificate and that of Dr. Johnson, one of the first two doctors to be called in, the magistrate gave the order.

With regard to the lady's delusions, the Lord Justice said that he would not hold for a moment that anybody who believed in hypnotism, telepathy, or thought transference was insane, but, taking all the evidence together, he had no doubt that any reasonable jury ought to find that the lady was under some kind of delusion that people, by hypnotic influence, could have carnal intercourse without touching each other, and that she herself had been psychically assaulted in the street. "When you find a doctor with that symptom presented to him it appears to me he has abundant evidence, if he is satisfied that the lady in course of conversation made that statement, for certifying the lady as of unsound mind." He instanced other peculiar delusions, such as that everybody who went about had a certain odour—another matter which influenced the doctor. Another thing which had influenced the Lord Justice was the letters and postcards written by the lady; the evidence that the lady was not of sound mind was supported by them.

Lord Justice Scrutton then went on to refer to an affidavit which had been put in by Dr. Risien Russell, "on whom I cast no reflection, and do not intend to cast any reflection, by saying that he is usually the principal witness for the plaintiff in lunacy cases." Dr. Russell's affidavit said nothing about this case, but he said, "I consider that in all cases where insanity is suspected a thorough physical, as well as mental, examination should be made, except in a case where the plaintiff's condition is so aggravated that such examination is impossible." Dr. Russell then went on to cite a series of physical examinations which ought to be made: "To examine the pupil of the eye; to employ an ophthalmoscope to detect pressure on the brain; to search for tremor of the face, tongue, and hands, to test for inco-ordination of the movements of the limbs, including the test for Romberg's sign; to examine the tendon reflexes of the limbs, notably as to the state of the knee-jerks and ankle-jerks; to test the superficial reflexes, in particular the plantar reflex of the soles of the feet." The Lord Justice continued: "When doctors who come to examine a patient are not employed by the patient, they have no authority to conduct all these operations, and in most cases the doctor intending to carry out all these tests would be strenuously objected to by the patient." Such delusions as had been referred to in this case appeared to be pretty conclusive as to the unsoundness of mind of the plaintiff, and the doctor would not find it necessary to ask the objecting patient to go through the physical tests suggested by Dr. Risien Russell. He gathered that but for this affidavit Mr. Justice Finlay would have stayed the action, but for his own part he was bound to confess that he was not impressed by it in the same way.

"Endeavouring as best I can to fulfil this very difficult jurisdiction and to hold the balance fairly between the desire to protect the liberty of the subject on the one hand, and on the other the desire to protect the doctors who are called upon by Parliament to exercise for the good of the community the duty of honestly expressing their opinion about patients, I come to the conclusion that these actions should be stayed on the ground that there is no evidence on which a jury could reasonably find either lack of good faith or lack of reasonable care."

Lord Justice Greer's Concurrence.

Lord Justice Greer, in concurring, said that he did not read Section 330 in the way Mr. Cremlyn, for the respondent, had read it. Mr. Cremlyn seemed to contend that an order for a stay could not be made under Subsection 2 of that section in a case where there was *some* evidence that there was want of good faith or want of reasonable care. The Lord Justice thought that to read the section in that way would be to make it practically of no effect whatever, because it was obvious that any person bringing an action alleging that he had been improperly certified by the doctors would be able to put before the court on affidavit a certain number of facts which, if proved, would support the action which had been commenced. "I do not think it means that. In my judgement the court has to look at the whole of the evidence which has been put before it, and has, so far as it is possible, to weigh the evidence which has been given on affidavit, to come to a conclusion one way or the other as to whether there is reasonable ground for alleging want of good faith or want of reasonable care." He added that in this case the question of want of good faith might be left out, because this was not suggested.

The Lord Justice then reviewed the facts of the case, saying that it seemed to him there was some evidence—though not a great amount—that the lady at the time of certification was in such a state of mind that she might become at any moment dangerous to herself. There was also convincing evidence of her behaviour from the time she was received into the first home until the time she came out—evidence which, if true, indicated that she was at that period a person of unsound mind. He thought the court was entitled to regard that as confirmatory

of the opinion of the two doctors at the first examination. She had delusions, and suffered from a state of depression, and there were threats or talks about suicide, which made it considered desirable that she should be put under restraint.

Coming to Dr. Risien Russell's evidence, Lord Justice Greer said: "If it is intended to lay down as a general rule that no medical man can safely sign a certificate without he carries out those physical tests which are mentioned in his affidavit, then I have no hesitation in saying that the affidavit ought not to be accepted by any court which knows anything whatever about the matter. It is ridiculous to suppose that a doctor cannot, without those tests, in any circumstances affording ample evidence of such delusional insanity as would justify a certificate, be warranted in certifying that a person should be placed under control." He thought there were many cases where the physical examination need not take place, though he did not mean to say that it ought to be regarded as a general rule that all tests should not be tried in cases of doubt. In the vast majority of cases it was most desirable that particular tests should be applied.

"Although it is a somewhat difficult matter, I have come to the same conclusion as my Lord—that in this case the order for a stay ought to be made."

The judgement recorded above is a very important one to the medical profession. In the case of Hume Spry v. Smith and Watson (*British Medical Journal*, 1926, i, p. 503) Lord Justice Bankes laid it down that it was not for the court at that stage of the proceedings to test the quality of the evidence before them with a view to determining whether or not there was reasonable cause for staying the proceedings. This, in the opinion of some, rendered Section 330 (2) and the relief it was supposed to afford of no avail. But Lord Justice Greer now states specifically—and Lord Justice Scrutton implies—that it is the duty of the court to weigh the evidence before it on an application to set aside a statement of claim.

Medical News.

THE Royal Westminster Ophthalmic Hospital, Broad Street, W.C., has recently started a new electro-therapeutic department for the purpose of studying the value of electrotherapy in the prevention and treatment of various eye diseases.

THE permanent postal address of the National Association for the Prevention of Tuberculosis is now Tavistock House (North), Tavistock Square, W.C.1.

THE Commonwealth Fund of New York City offers annually to men and women graduates of universities in the British Empire thirty Fellowships, tenable for two years, in the graduate schools of certain universities in the United States. Each Fellowship includes provision for tuition and living expenses, with ample allowances for ocean passage and travel in the United States during vacations. Unmarried men and women of British descent, under 30 years of age, who have graduated and who can produce evidence of proficiency in some recognized branch of university learning are eligible. Applications for Fellowships tenable for 1930-32 will be received until February 10th, 1930. Further information and forms of application can be obtained from the secretary of the Commonwealth Fund Fellowships, 50, Russell Square, W.C.1.

LORD CORNWALLIS, chairman of the Kent County Council, will preside over the forty-first congress and health exhibition of the Royal Sanitary Institute to be held at Margate from June 21st to 28th, 1930. Dr. Andrew Balfour will preside over the section of preventive medicine; Sir Henry Maybury over the section of engineering and architecture; Lady Howard de Walden over the section of maternity and child welfare, including school hygiene; Major-General Sir John Moore over the section of veterinary hygiene; and Sir Thomas Neill over the conference on national health insurance services.

THE tenth congress of the Journées Médicales de Bruxelles, which was to have been held from June 21st to 25th, 1930, has been postponed to June 28th to July 2nd, so as not to clash with the inauguration of the new university buildings at Brussels.

THE fifth congress of Northern neurologists will be held at Stockholm under the presidency of Professor H. Marcus in August, 1930, when the subject for discussion will be epilepsy and its treatment.

A COURSE of clinical and laboratory instruction in malaria will be held at the Scuola Superiore di Malariologia, Rome, from July 1st to September 30th, 1930. The fee is 300 lire. Further information can be obtained from the secretary of the school, R. Clinica Medica, Policlinico Umberto I, Rome.

DR. CONSTANTIN ECONOMO, professor of psychiatry and neurology in Vienna, has been invited to lecture at Columbia University, New York, on his recent researches on the brain.

A NEW edition of the *Europa Year Book* will be issued next February in a different form. The primary material will appear in six monthly sections, with the first of which subscribers will receive a loose-leaf case for containing them; in this way continuous revision will be possible, enabling the book to keep up to date. The cost will be two guineas for two years; this will include the loose-leaf case, the primary material, and twelve supplements. The publishers announce that they will be prepared to answer inquiries, or provide further information on any point within the scope of this useful annual. Further information may be obtained from Europa Publications, Ltd., 6, Duke Street, Adelphi, W.C.2.

WE have received the second part of the report of the seventh congress of the Far Eastern Association of Tropical Medicine, which was held in India in December, 1927. It contains the opening addresses, the speeches at the general business meeting, a summary of the proceedings of the scientific sections, and lists of the members and officers of the congress and of the association, together with its articles and by-laws. It is announced that Parts I, III, and IV, dealing with the organization of the congress in its various aspects, have not been published.

MME CHARLES LOUIS-DREYFUS, in memory of her late husband, has presented to Dr. Louis Mourier, Director of the Assistance Publique, a cheque for 100,000 francs to be devoted to a children's hospital in Paris.

THE late Colonel W. E. Walker has bequeathed £8,000 to the Bolton Infirmary for a bacteriological and pathological laboratory.

DR. BUCKY of New York has succeeded the late Professor Levy-Dorn as director of the Roentgen Institute of the Rudolf Virchow Hospital, Berlin.

DR. J. WALTER CARR, consulting physician to the Royal Free Hospital and the Victoria Hospital for Children, Chelsea, has been elected Master of the Haberdashers' Company.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9361, 9362, 9363,* and *9364* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

LANDRY'S PARALYSIS.

"E. P." would be glad to hear from anyone who has had experience of Landry's paralysis. He is convalescent from the disease and would like to compare notes.

DENTAL ANAESTHESIA FOR CHILDREN.

"G. F. R. S." writes: "W. D." raises a difficult question, for, as in other forms of anaesthesia, there is no golden rule. Ethyl chloride is, as a rule, better than ethyl nitrous oxide for single administration; for multiple extractions the ethyl chloride-ether sequence is as satisfactory as any other. Smooth induction is merely a matter of practice, and it can be done in the case of children equally well either on an open mask or with a Hewitt's modification of a Clover inhaler. The difficulty with a face-piece can be overcome by a pad of gamgee, such as is used in the open method. Continuous gas in experienced hands also gives moderately good results, but dental anaesthesia should be in the hands of experts.

CHRONIC URTICARIA.

DR. J. A. NOBLE (Bournemouth) writes in reply to "X. Y." (December 7th, p. 1093): Five cubic centimetres of the patient's blood is taken by syringe from any superficial vein and rapidly (to prevent clotting in the needle) re-injected intramuscularly deep in the buttock. This causes little pain, and no after-rest is necessary. Two such injections, at an interval of seven days, cured a severe case of several years' standing, which had recurred after ultra-violet ray treatment, and had resisted treatment by calcium and intestinal disinfection. One injection caused the disappearance of an exactly similar urticaria in less than a week in a case of shorter duration. Both patients were young farmers and, when I last saw them, both had been free from recurrence for over twelve months. I should be grateful if "X. Y." would inform me if the treatment is successful.

TREATMENT OF CHRONIC PRURITUS ANI.

DR. STANLEY E. DENYER (Hull) writes in reply to "H. F." (December 14th, p. 1142): I have recently treated a patient with *chronic pruritus ani with ultra-violet rays, using a quartz* mercury vapour type lamp, at a distance of 3 ft., for two minutes. Used once weekly this gave considerable relief. In a severe case it would be better to give it twice-weekly, but not oftener.

DR. HENRY WALDO (Clifton) writes: The late Dr. Radcliffe Crocker's favourite application for chronic pruritus ani was hydrarg. ammon. 20 grains, adeps benz. 1 oz.

DR. W. H. HOOTON suggests, in reply to "H. F.'s" inquiry, that *x-ray therapy should be tried.*

"J. R." writes to say that he has found ung. quinolin comp. (made by the British Drug Houses, Ltd.) successful in a very troublesome case.

INCOME TAX.

Amalgamation of Practices.

"L. B. S." explains that, as from April 1st, 1929, his practice was merged with that carried on by two other practitioners, A and B. The inspector of taxes has informed him that his liability for the years 1927–28 and 1928–29 will be revised under Section 31 of the Finance Act, 1926, the assessments being increased to the amount of the actual profits of those years. Is this correct and, if so, why?

*** Under the scheme of assessment as laid down in the Finance Act, 1926, the taxpayer is entitled, under Section 29, to have the assessment for the year following that in which the business or practice was set up reduced to *the amount of the* actual profit of that year; Section 31 gives the Revenue a corresponding option when "a trade or profession is permanently discontinued"—that is, to increase the penultimate year's assessment to the amount of *the actual profit. Both the* commencing and final years are also chargeable on that basis. Permanent discontinuance does not apply to the individual, but to the business or practice. The reason for Section 31 is clear; large profits may easily be followed by a break up of the business entity, so that the amount of profits earned in the final year—say, to September 30th, 1928—would never come into a computation for income tax without some such provision. Our correspondent does not say how the new firm, consisting of A, B, and himself, is being assessed. If the facts are that the firm is being assessed for 1929–30 on the basis of the earnings of all three for the year to April, 1929, then the equitable justification for the application of Section 31 seems lacking; if, therefore, the new firm would be assessable at a smaller figure for 1929–30 on the basis of that actual year, "L. B. S." might point out to the inspector of taxes that he seems to be employing Section 31 in a way which was not intended, and, in the event of his maintaining *his present attitude*, "L. B. S." might put the full facts forward in a letter to the Board of Inland Revenue, Somerset House, and ask for their special consideration of the case.

LETTERS, NOTES, ETC.

QUININE FOR THE ORDINARY COLD.

DR. A. W. DAVISON (Manchester) writes: As Dr. Denyer's suggestion of quinine sulphate in cooking sherry t.d.s. (December 14th, p. 1142) works out, according to my [illegible] I gram to the ounce, and as this [illegible] minim, perhaps the latter would convenient.

THE HISTORY OF INTENSIVE ALKALINE TREATMENT.

DR. D. ROBERTS (Holyhead) writes: It may be of interest to recall that the late William Jones, M.D., of Caeceilio, Anglesey, was a pioneer in the *practice of intensive alkaline treatment.* His usual prescription contained sodii carb. 25 grains or more, mag. carb. pond. 5 or 6 grains, with pulv. zingib. 3 or 4 grains—occasionally cretæ præparata 5 grains was added, after every meal, in water. He gave a powder at bedtime composed of alumnis 1/2 dr. and mag. carb. pond. 5 or 6 grains. The formula was often varied and sometimes ordered in bulk—1/2 dr. for a dose after every meal, in water. Dr. Jones was a remarkable man. He started in life as a farm hand. One day, when out with his team, he went to the assistance of a lady rider who was unhorsed, and in the fall she fractured her arm. This raw youth did both "first" and *final* "aid"; as a doctor who saw her *subsequently declared*, he could do nothing more, for the fracture was "set" perfectly. This lady helped him in his future career, and he had a brilliant college course. He was born in 1815 and died in 1882.

THE USE OF THE TONSILS.

DR. P. G. DANE (Melbourne) writes: Continuing the discussion in the *Journal* on the use of the tonsils (May 25th, p. 980, and June 1st, p. 1024), I should like to know if the following is a common experience. In August, 1928, I had my tonsils carefully enucleated on account of a toxic labyrinth; the tonsils were definitely "septic." Within four months I had developed two large masses of lymphoid tissue behind the posterior pillar. These masses have almost the appearance of true tonsils, and each became slightly inflamed, with enlargement of the cervical glands, during an epidemic of influenza. It would thus appear that the tonsils have a definite function, even at my age (48 years), and that when removed the lingual tonsil undergoes a compensatory enlargement. It is rather difficult to understand how an organ that is *present in all mammals, from the* marsupials upwards, is without some important function. The tonsil is not present in the Australian monotremes—the echidna and the platypus; what is the impetus that has caused its appearance in the marsupials?

TREATMENT OF BURNS AND SCALDS.

"M. W." (Warwickshire) writes: The article in the *Journal* of November 2nd on the tannic acid treatment of burns prompts me to record my experience with an older method, which I have used for years, without failure, except in one very young child, who died from shock within a few hours. The patients are quite comfortable from the first, and do not appear to suffer from any constitutional disturbance. The treatment is simply carron oil—that is, lime water and linseed oil, of each equal parts—to every ounce of which 1/2 drachm of tr. opii is added. Strips of lint or old linen are soaked in this and applied to the affected parts. This stops the pain at once, and it is wonderful how little sepsis or sloughing occurs. If a part later on becomes septic or shows *signs of sloughing, I bathe this part with boric acid lotion and* apply boric ointment. If deep sloughing occurs still later I should treat with warm (not hot) boric fomentations. About a year ago two cases occurred within quite a short time of each other, in the same district. In each case the extent of surface involved and the degree of severity were about the same. One patient I treated in the way I have just outlined, and with very little discomfort; she made a complete recovery. The other case I sent to hospital on account of "fussy" parents. I believe she was treated from the beginning with antiseptics, and I was *told she suffered intensely before her death a few days later.*

FAMILIAL GASTRIC ULCER.

DR. S. B. TURNER (Bargoed) writes: The following series of cases of gastric ulcer occurring *in one family appears to be so extra*ordinary that it might be of interest to any surgeon specially keen on the subject. The father and mother, aged 68 and 65 respectively, were quite healthy.

1. David H., son, aged 42, was operated on in 1921 for typical gastric ulcer, *after* x-ray examination; gastro-jejunostomy. In September, 1929, he had perforated gastric ulcer; operated upon; recovery. This was quite a separate ulcer from the first.

2. Mrs. R., daughter, aged 45, had typical gastric ulcer, shown by x-ray examination; gastro-jejunostomy, recovery.

3. Ivor H., son, aged 30, had perforated gastric ulcer in 1926; operation, recovery.

4. Lewis H., son, aged 31, now has typical gastric ulcer and is awaiting operation.

Two of these patients are non-smokers; one is a light smoker. Their diet is the usual one of a colliery family.

THE CHOCOLATE SEASON.

IT was Thackeray, we think, who said somewhere that every pure unsophisticated palate likes chocolates. To those who agree with him and with us on this subject, Cadburys offer a remarkably wide choice of boxes of chocolates, varied in design and price to meet the wishes of the simplest editor and the most fastidious reader. The manufacturers, in sending us a Christmas packet of their agreeable wares, suggest that for parties—or, indeed, for any happy occasion—we shall be wise to serve Cadbury's "cup chocolate." This new beverage *chocolat* can be made instantly with boiling milk.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 39, and 40 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 279.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

570. Diurnal Blood Sugar and Urine Sugar Curves.

AS J. NEUBURGER points out (*Dent. med. Woch.*, November 8th, 1929, p. 1876), variations in blood sugar do not in large numbers of diabetic patients produce corresponding changes in subjective symptoms; diurnal fluctuations have therefore not received sufficient attention hitherto. Some patients are also apparently so resistant to insulin that they do not excrete entirely sugar-free urine unless large doses are combined with a low carbohydrate intake, a regime which is at the same time very apt to induce hypoglycaemic symptoms. This discrepancy between a high fasting blood-sugar figure, glycosuria in the morning urine, high doses of insulin, and liability to hypoglycaemia is due to the short duration of the effect of doses of insulin. One diabetic patient, in whom at first 60 to 80 units daily in two injections, and later 60 units in three injections, had proved satisfactory for some months, suddenly developed severe hypoglycaemic symptoms on several successive days while on the latter dosage; blood sugar estimations showed that the diurnal range was from 360 mg. per cent. in the morning to 35 mg. per cent. in the evening. In order to control these fluctuations and remove the risk of hypoglycaemia it was found necessary to administer 10 units at 6 a.m. and 10 at midnight, and to spread the remaining 40 over the course of the day. The urine sugar curve from analysis of two-hourly specimens followed the blood sugar curve closely. For practical purposes in private practice in the less severe cases Neuburger suggests that an occasional examination of a series of two-hourly specimens is a useful check on the efficacy of a given dosage of insulin. In this way large diurnal fluctuations in blood sugar (as reflected in the urinary excretion) can be prevented, and by this means the risk of hypoglycaemia is diminished. A comparatively constant blood sugar value is, moreover, much better for the patient's general condition than large fluctuations. In the more severe cases, and in those patients receiving large doses prior to operation, the two-hourly urine curve is not sufficiently accurate; frequent blood sugar estimations during the twenty-four hours are essential.

571. The Spinal Cord in Diphtherial Paralysis.

C. SEGAL (*Thèse de Paris*, 1923, No. 232), who records nine illustrative cases in patients aged from 9 to 44, maintains that involvement of the spinal cord, meninges, and sometimes even of the brain, undoubtedly takes place in diphtherial paralysis, as is proved by clinical, pathological, and experimental evidence. The important symptoms, in order of frequency, are predominance of the paralysis in the extensors, a meningeal reaction, dissociation of paralysis and anaesthesia in the same area, and sphincter disturbance. In one of Segal's cases Babinski's sign indicating involvement of the pyramidal tract was found. Segal thinks that in the early stage with merely paralysis of the soft palate it would be an exaggeration to attribute it to a central spinal lesion, when a toxic polyneuritis only is present. The toxin, however, is conveyed to the central nervous system by a process of ascending neuritis. The central lesion, therefore, is always secondary to a localized peripheral involvement. The central lesions are often latent, but can frequently be detected by a systematic examination. This explains the extension of the paralysis, the presence of spinal symptoms, and a motor or sensory involvement which is quite independent of the areas of peripheral distribution. In conclusion, Segal suggests that the intraspinal injection of antitoxin as well as local radiotherapy might be of benefit in diphtherial paralysis.

572. Widespread Trichiniasis Infestation.

S. S. HORLICK and R. E. BICKNELL (*New England Journ. Med.*, October 24th, 1929, p. 816) report an unusual case in which there was simultaneous trichiniasis infestation of more organs and tissues than had been previously recorded in any one patient. A woman, aged 52, was suddenly seized with severe headache, starting at the back of the neck and radiating upward and forward from the occipital to the frontal and parietal regions. The following day orbital pain and oedema of the eyelids lasting for thirty-six hours occurred, and pains and tenderness, unrelieved by opiates, were diffused throughout the muscles of the shoulders, arms, and back. Eight days before the appearance of the severe symptoms she had eaten a well-broiled pork chop, and a daughter who had partaken of the same meal complained of pain and soreness in the back lasting two days. A series of relapses with spread of symptoms ended in death. The diagnosis of trichiniasis was evident from the characteristic clinical picture of oedema of the eyelids, muscle pain and tenderness, and eosinophilia. This was confirmed by finding the larval form of the *Trichina spiralis* in the blood and throughout all the sections of the muscle tissue taken from the diaphragm, abdominal, psoas, and thigh muscles. Of chief interest was the finding of encysted trichinae in the heart muscle, pancreatic tissue, kidneys, and intestinal musculature, and in the gall-bladder, which was enormously distended with straw-coloured fluid containing trichinae. Permission could not be obtained to examine the brain and spinal cord, but the symptoms during life were significant of infestation of the central nervous system.

573. Toxicosis in Asthma.

A. J. D. CAMERON (*Med. Journ. and Record*, November 6th, 1929, p. 525) regards toxicosis as a basic factor in asthma, his view being borne out by the results of treatment for chronic nasal catarrh by thorough detoxication and local treatment to any foci discovered, since as the nasal catarrh cleared up so did the asthma. Evidence of such a basic toxic factor was easily obtained from the blood and urine, and the bowel appeared to be the chief source, with consequent impairment of liver efficiency; secondary foci in gall-bladder, nose, throat, or teeth are considered as being primarily due to the disturbed metabolism which constituted the first step, the bacillary implantation being the second. In many chronic toxic cases with identical blood and urine conditions no asthma was present unless the ethmoid area was involved, so that three definite conditions seem to be required for the syndrome—namely, a basic toxic condition, an irritable nervous system, and ethmoid implication. The urine in these cases showed high specific gravity, urates, a disturbed acid ratio, with high sulphate, chloride, and uric acid contents. The protein is always increased correspondingly with the degree of toxicosis; the calcium figure was low. There was evidence in the blood also of the toxic process, the amino-nitrogen, uric acid, and bilirubin being raised. The author considers that too much attention is being paid to infective organisms, and too little to the underlying metabolic error. He consequently does not find vaccines of value in treatment, which in his opinion resolves itself into thorough detoxication, nasal tampons, nasal surgery when necessary, and dieting.

Surgery.

574. Surgical Treatment of Gastric Ulcer.

M. MADLENER (*Zentralbl. f. Chir.*, October 26th, 1929, p. 2694) describes an operation which he terms "palliative resection"; in cases of gastric ulcer *remota from* the pylorus the diseased portion is left and the pylorus removed. This is held to be not illogical, on the ground that the ulcer is not a disease itself but only a symptom. Moreover, the results obtained are said to justify the procedure; 17 cases (10 women and 7 men) watched for seven years have all done well. In 13 cases the ulcer was juxtacardiac, 7 being callous and 6 penetrating. In all these the inferior half of the stomach was resected and the Billroth I anastomosis performed; in only one case was the Billroth II procedure necessary, a duodenal ulcer being also present. In the remaining four cases there was a large penetrating central gastric ulcer associated with perigastritis. In these cases the operation was limited to pyloric antrectomy, a narrow strip of about two inches being removed, and continuity restored by means of the Billroth I technique. All the 17 patients were quite free from their previous pain within a few days after the operation. In 16 cases the pre-operative pain and discomfort did not return subsequently, but in one case, though there was great improvement in this respect, partial stenosis due to the ulcer persisted. Nearly all the patients resumed work, some undertaking heavy manual labour. There was in the series an average gain of 8 lb. in weight, and the patients' tolerance for food was good. The author concludes that resection of an ulcer is undoubtedly the best procedure unless it necessitates too much risk, which is often the case. In such circumstances an indirect operation is indicated, such as gastro-enterostomy, pyloro-myotomy, jejunostomy, or "palliative resection," which Madlener ranks as the most successful of all.

575. Surgical Treatment of Hyperthyroidism.

THOUGH admitting that the surgical treatment of hyperthyroidism is unsatisfactory and has its limitations, G. S. FAHRNI (*Canadian Med. Assoc. Journ.*, November, 1929, p. 511) considers that it is the most satisfactory method in our present state of knowledge, and that efforts should be concentrated on increasing its efficiency. The surgical management of this condition is discussed under three headings: complications, mortality, and recurrence. A complication is always more serious in very sick people, therefore an effort should be made to obtain a maximum degree of improvement before operation, to avoid complications, and to adopt a fast, accurate technique. A strong advocate of the judicious pre-operative use of Lugol's solution, Fahrni greatly depreciates its indiscriminate, periodical, and sometimes prolonged use in hyperthyroidism. A patient, after his first favourable reaction to iodine (the optimum operative period), may relapse at a later date, after which iodine seems much less efficient, and becomes a more serious operative risk. Haemorrhage is one of the commonest complications of thyroidectomy, and complete haemostasis should be obtained before the wound is closed. Secondary haemorrhage will occur only following infection of the wound. Injury to a recurrent laryngeal nerve may be a very serious complication, and the position of the nerves should be thoroughly understood and avoided. Tetany, which is rather rare, can best be avoided by leaving intact a considerable portion of the posterior capsule of the thyroid on both sides of the trachea. Acute post-operative hyperthyroidism is very rare when the patient has previously been thoroughly iodized. In 844 consecutive thyroidectomies only 8 (0.92 per cent.) deaths occurred. Long-standing hyperthyroidism in old people is always serious, and the duration of the disease and the age of the patient are important factors in considering operative risks. Five of the fatal cases were in persons over the age of 50, and in all the fatal cases the disease had lasted for one to thirty years. Recurrences may appear a few months or many years after operation, and are signalized by a return of many of the old symptoms. At this period Lugol's solution should be given in comparatively small doses (5 to 10 minims) twice daily, the dose being gradually diminished as the symptoms abate. Fahrni advises a fairly radical operation, leaving only a small amount of thyroid tissue. This favours complete recovery, and in such cases the judicious post-operative use of iodine, together with an orderly mode of living, should prevent any recurrence.

576. Multiple Tuberculous Arthritis.

J. L. HARVEY and I. C. HALL (*Radiology*, December, 1929, p. 526) record a case of multiple tuberculous arthritis simulating malignancy and the Charcot joint. A man, aged 60, complained of painful swelling of the left elbow; he had two less painful walnut-sized lumps near the right wrist, and another below the left knee. He was lame owing to dislocation of the left hip in infancy, but otherwise had always been healthy. The left elbow was greatly enlarged and without movement. The swelling below the left knee was a benign chondroma. X-ray findings of the right wrist were strongly suggestive of a Charcot joint. Pus aspirated from the tumour of the left elbow contained organisms resembling the tubercle bacillus, and the results of inoculating guinea-pigs and rabbits suggested that the organism was of the human type. The authors emphasize the localizing effect of unrepaired bone injury with consequent metastasis, and they point to the necessity for complete laboratory examination in establishing a diagnosis. They regard the early dislocation of the hip as determining a chronic tuberculosis of the joint with subsequent lesions of other joints developing sixty years subsequently; the true nature of these later lesions could only be ascertained by guinea-pig tests.

577. Primary Tuberculous Peripleuritis.

UNDER this title P. CHEVALLIER (*Arch. Méd.-Chir. de l'Appareil Respirat.*, May, 1929, p. 197) discusses a rather rare condition of the diaphragm which is apparently not usually diagnosed during life. It consists in a chronic type of tuberculous affection of the surfaces of the diaphragm, beginning with vague pains in the side or gastric area suggestive of gastric trouble and proceeding eventually to marked cachexia and death. As a rule the deposit is in the shape of thick lymph and seldom causes effusion. In the early stages the patient does not look ill or suggest tuberculosis, but generally complains of stomach symptoms; later on progressive wasting and weakness set in. In walking he is apt to bend forward so as to relieve the pain, and, when asleep, curls up; constipation is common. Radiography does not help very much in diagnosis. Death usually occurs from extension of the tuberculous infection. The author publishes two cases illustrating the disease, and reproduces the histological appearances of the affected diaphragm.

Therapeutics.

578. Sodium Ricinoleate in Allergic Intestinal Diseases.

THE fact, first demonstrated by Larson, that sodium ricinoleate is capable of neutralizing bacterial poisons, led R. S. MORRIS and S. E. DORST (*Amer. Journ. Med. Sci.*, November, 1929, p. 631) to treat patients showing evidence of allergy of intestinal origin with this drug. Since oils are converted into soaps in the intestines, they felt that there was a possibility that bacterial poisons, if present, might be neutralized by the ricinoleates formed in this part of the alimentary canal; the clinical results are stated to have supported this theory. After the administration of sodium ricinoleate, patients have, as a rule, experienced very prompt relief of the feeling of distension and excessive gas formation, a lessening of fatigability, and a diminution or abolition of various symptoms such as headache and neuralgic muscular pains. The palpitation, tachycardia, and nervousness so frequently associated with excessive gas formation are also benefited, and the stools become less offensive. Some patients who have obtained marked subjective relief have reported recurrence of the symptoms on cessation of treatment. The authors have given as many as six 5-grain capsules daily, though the majority of the patients received only three a day. The drug appears to be entirely non-toxic in these doses; this, it is added, was to be expected, as it is the sodium soap of castor oil.

579. Bismuth and Neoarsphenamine in Syphilis.

J. F. SCHAMBERG (*Arch. Derm. and Syph.*, October, 1929, p. 431) pleads for a more cautious administration of the arsenobenzenes. He admits that accidents following the exhibition of these drugs may be due to some defect in the preparation or the technique, or to an idiosyncrasy of the patient, but he is of the opinion that if all factors are taken into consideration there is greater safety in employing less heroic, but perhaps more frequent, doses. The fact must not be overlooked that the patient must be considered carefully as well as his disease, and Schamberg claims that while his results are comparable with those of other workers they have been obtained with far fewer accidents. He prefers neoarsphenamine in spite of its occasional variability, and treats his patients simultaneously with bismuth. The patient usually attends once a week and receives an intragluteal injection of 100 mg. of potassium tartro-bismuthate, followed immediately by a dose of 0.3 to 0.45 gram of neoarsphenamine. The treatment is continued until about 5 grams of the latter has been given; if the Wassermann reaction of the blood and spinal fluid is then negative, the bismuth alone is continued until a total of 2 grams has been injected. This constitutes the first course of treatment, and similar courses with bismuth or mercury are afterwards arranged.

580. Vaccine Treatment of Typhoid Fever.

K. KYRIAZIDES, C. PERAKIS, and P. CALOGEROU (*Bull. Méd.*, October 5th, 1929, p. 1057) record their observations on 251 cases of typhoid fever at Athens, treated by Vincent's anti-typhoid vaccine, which in 112 cases was given intravenously and in 139 subcutaneously. Their conclusions are as follows. Antityphoid vaccine therapy is a safe method which shortens the duration of the disease in 86.2 to 87.4 per cent. of all cases. The result is obtained much more rapidly by the intravenous method, and in 61 per cent. of such cases the treatment has an abortive effect. The earlier the treatment is started the better the results. As a general rule the most suitable dose for intravenous injection is 25 million bacilli given in one injection (successful in 61 per cent.), whereas three injections of 200 million (successful in 61.72 per cent.) are required for subcutaneous injection. When a successful result was not obtained by these doses it occurred later on continuation of the treatment (in 26 per cent. by the intravenous method, and in 34 per cent. by the hypodermic). Vaccine treatment does not give rise to complications. The mortality of typhoid fever treated by vaccines is relatively very low—namely, 7.14 per cent. with the intravenous method, and 7.91 per cent. with the subcutaneous method. Of the two methods the intravenous is held to be the more suitable for clinics and hospitals, while the subcutaneous method can readily be employed in private practice.

531. A Simple Method of Administering Carbon Dioxide.

THE value of carbon dioxide as a stimulant of the respiratory centre in unconscious and anaesthetized patients for accelerating the return to consciousness is generally acknowledged; but, as A. STERN (*Münch. med. Woch.*, October 25th, 1929, p. 1797) points out, the unwieldy character of the usual CO_2 cylinders has hitherto limited the use of this gas in private practice when a rapid return to consciousness after

an anaesthetic for some minor surgical operation means much valuable saving of time. It is also useful, when the airway has been cleared, in stimulating respiration in semi-asphyxiated newborn infants. He has therefore improvised a substitute for the gas cylinder as follows: an ordinary soda-water siphon is half emptied and then inverted and the last drops of water expelled from the tube by pressing the lever. A piece of rubber tubing is then attached to the cock. On pressing the lever a current of CO_2 gas under low pressure streams out of the bottle along the rubber tubing, the distal end of which is inserted into the patient's nostril.

Disease in Childhood.

582. Congenital Cardiac Disease in Identical Twins.

K. SHIRLEY SMITH (*Arch. Dis. in Childhood*, October, 1929, p. 330) comments on the rarity of congenital cardiac abnormalities in paired offspring, and discusses these conditions in homogeneous twins. Three cases of dextrocardia with complete transposition of the viscera have been reported in the literature. These occurred in one instance in only one of the twins; in the other it was noted in both of the adult identical twins. Martinotti and Lochte have shown that transposition of the viscera in monsters depends on the persistence of the omphalo-mesenteric vein, and that secondary rotation of the heart is usual but not inevitable. If identical twins are regarded as separated double monsters, the application of these principles to such twins becomes apparent. The present author reports cases of patent ductus arteriosus in each of a pair of twins, and four like cases have been previously recorded. All these showed the following similarities: absence of physical signs in the cardio-vascular system; the presence of a patent ductus as a solitary cardiac defect; and the occurrence of attacks of cyanosis with arrest of the breathing, these attacks sometimes ceasing spontaneously and sometimes yielding to oxygen or the injection of cardiac stimulants. The most likely explanation of the cyanosis is a change in the blood supply to the lungs caused by a reversal of the direction of flow through the patent ductus arteriosus. If the blood is deflected from its normal passage through such an abnormal one into the systemic circulation, progressively increasing cyanosis must follow. The cause of the deflection of the blood from the pulmonary circuit, and the frequent termination of the attack with a return to normal conditions, remains to be explained. The most probable causes of increased resistance in the pulmonary circuit are any muscular effort (crying or coughing) and engorgement of the pulmonary capillaries. If reversal of the blood flow is the cause of cyanosis, the same cause acting in an opposite direction must terminate the attack; this reversal may be explained by the rise in arterial blood pressure which accompanies asphyxia. The absence in these cases of the "mill-wheel" murmur, typical of a patent ductus in adults, may possibly be due to anatomical reasons. If the ductus is straight and of uniform bore no murmur is produced, while a spindle-shaped dilatation of the channel, not uncommon in the adult, may cause the continuous bruit.

583. Juvenile Diabetes.

H. SEHESTEDT (*Med. Welt*, September 28th, 1929, p. 1396) discusses the recognition and treatment of juvenile diabetes. To illustrate how easily the disease may be overlooked he describes two cases. A child, aged 12, began to suffer from fatigue, abdominal pain, and great thirst; the condition was attributed to the child having outgrown his strength and to gastric catarrh. He was sent to the country to recuperate, but on the second day passed into diabetic coma. Another boy gradually lost weight and suffered from constipation, with great thirst. The symptoms grew worse, sugar was found in the urine, and the child died. The author remarks that the great improvement in prognosis which results from modern therapy makes it imperative to recognize diabetes at the earliest stage possible; if suitably treated a juvenile diabetic patient will probably have the average span of life. Watch should be kept for the early signs of juvenile diabetes, which resembles this condition in the adult, but the thirst is much more pronounced. Parents may not observe this, and are more apt to notice the polyuria; this may first manifest itself as nocturnal incontinence. In a child in whom this condition recurs after it has apparently been cured, diabetes should be suspected. Abdominal pain and nausea are common and readily give rise to suspicious of abdominal disease. With the exception of rubeosis diabetica, the juvenile skin is exempt from complications common in the adult; dental and mucous membrane complications are similarly rare in the child. Balanitis occurs, but ocular and nervous lesions are relatively rare; sudden changes in refraction always call for a urinary test. After diagnosis it is best to send the patient to a clinic where his correct dietary and insulin dosage can be determined and the information be forwarded to the practitioner for treatment after discharge. When diagnosis is delayed until the appearance of coma 50 units of insulin should be injected if no hospital is available. Coma has not necessarily the same evil significance as in adults.

584. Enteric Fever in Infants.

J. PICOT (*Thèse de Paris*, 1929, No. 234), who records nine cases in children aged from 10 months to 3½ years, five of whom had typhoid fever, one paratyphoid fever A, and three paratyphoid B, maintains that enteric fever is more frequent in infants than is supposed. According to Marfan, in every case of prolonged fever in which tuberculosis, otitis, pyelocystitis, and meningitis can be excluded, Widal's test should be performed. Etiologically the agents of transmission of enteric are the same in the infant as in the adult—namely, milk, water, flies, and carriers—while previous gastro-intestinal disturbance acts as a predisposing cause. The clinical picture is generally incomplete as compared with that in the adult, the predominating symptom being persistent fever. The most frequent complications are broncho-pneumonia, then acute meningitis, and intestinal complications. Relapses are frequent, and often considerably prolong the course of the disease. The younger the child the graver is the prognosis. The diagnosis must be made from ordinary diarrhoea, which is not accompanied by enlargement of the spleen or rise of temperature, and dysenteriform and choleriform diarrhoea, as well as from meningitis and broncho-pneumonia. Laboratory examination, in the form of a blood culture or Widal test, is necessary to make a correct diagnosis.

Obstetrics and Gynaecology.

585. Surgical Treatment of Fibroids in Pregnancy.

BÉGOUIN (*Journ. de Méd. de Bordeaux*, November 20th, 1929 p. 891) discusses the relative values of myomectomy and hysterectomy in dealing with fibroid tumours of the pregnant uterus. He remarks that, until the last five or six years, he had agreed with the majority of surgeons that true myomectomy—namely, the abdominal enucleation of interstitial fibromas—should be regarded as only to be performed exceptionally, in view of its being a more serious undertaking than subtotal hysterectomy. He thinks, however, that it is possible that patients are coming earlier for treatment, and, consequently, with less fully developed fibroid growths; the proportion of those cases suitable for myomectomy may therefore be larger of late. He believes that this increase will not continue much further, and that hysterectomy will remain the preferable operation in most cases. Bégouin insists, nevertheless, that hysterectomy is only justifiable when indicated by the anatomical distribution of fibrous growths in the uterus and its appendages, or by such physiological considerations [illegible] the patients. Although many surgeo[illegible] the graver operation, this is not [illegible] it is only employed for selected cases in which the fibroid growths are few and their removal does not injure the uterus extensively. The author concludes, therefore, that these two operations should be ranked as of equal severity when due care is taken to apply them to suitable cases. He urges conservative treatment whenever possible in the case of young women, and even in those about the age of 40, for in many cases removal of the uterus can be obviated and the possibility of pregnancy retained.

586. High Forceps Operations in Extern Practice

G. DÖDERLEIN (*Zentralbl. f. Gynak.*, November 2nd, 1929, p. 2781) remarks that most German authorities agree that a further extension of the indications for Caesarean section for dystocia is unjustified, and that the classical indications for vaginal delivery still hold good, being fraught with less danger to the mother. One of the most serious operative vaginal interventions is the high forceps operation. This is necessitated in cases in which version is contraindicated by imperfect motility of the foetus after draining away of the liquor amnii, usually on urgent maternal indications (such as persistent increasing fever, eclampsia, accidental haemorrhage, or exhaustion), but occasionally for such foetal causes as prolapse of the cord, or ominous variations in the heart rate. The great majority of authorities, it is stated, consider that the high forceps operation is suitable for hospital practice only, and should not be undertaken, as a rule, in the patient's home. Döderlein does not share this opinion, and cites 63 cases in which during the last three years, in the extern practice of the Berlin Universitäts-Frauenklinik, forceps were applied in the patient's house to a foetal head above or in the pelvic brim; in two-thirds of the cases the indications of urgency were maternal. The maternal mortality was *nil*,

the foetal about 40 per cent. Tears of the cervix occurred in 6 cases, of the vagina in 7, and of the perineum in 6; anterior hysterotomy was performed in 3, incisions of the os were made in 20, and episiotomy was performed in 28. Seven of the foetuses had had to be perforated (some while still living) after unsuccessful forceps application. Döderlein speaks favourably of the forceps described by Zweifel (*Zentralbl. f. Gynäk.*, 1926, No. 10), which is intermediate as regards its pelvic curve between the ordinary and Kielland types. It is concluded that a skilled accoucheur is justified in undertaking the high forceps procedure, in cases of need, in the patient's house; he must, however, recognize that he is performing a major obstetric operation, and that maternal injuries may occur the treatment of which may involve considerable technical difficulties. He should not undertake the high forceps operation unless he is also prepared, in case of its failing, to perform the operation, then imperative, of perforation, even if the foetus is not dead.

587. The Naegele Pelvis

J. WHITRIDGE WILLIAMS (*Amer. Journ. of Obstet. and Gynecol.*, October, 1929, p. 504) describes a case of that rare pelvic condition first recorded ninety years ago by Naegele, and so named subsequently. The patient, who was 27 at the time of her death, had had six spontaneous labours with small children, but she died from uterine rupture after delivery of the seventh, in which the foetus was larger than the preceding. The weight of the largest previous child born was 2,900 grams, and it had a biparietal diameter of 8.75 cm.; while in the seventh and fatal delivery the child weighed 3,400 grams and had a biparietal diameter of 9.5 cm. The patient walked without a limp, and although careful inspection did reveal an abnormal bodily habitus, it was so slight as almost to escape detection. After her second confinement a "list" to the left when she walked aroused curiosity, and ultimately, after detailed examination, the existence of a Naegele pelvis was diagnosed. There was nothing in the history to indicate that the patient had at any time suffered from inflammatory bone disease. She had never been bed-ridden; on the contrary, she was reported always "light upon her feet." Physical examination failed to reveal any trace of scars about the thighs, and an *x*-ray examination was negative. The next four labours were conducted by a midwife, and were normal. The bony articulation of the left sacro-iliac region did not show any signs of inflammatory process. The author considers that the findings tended to indicate that the deformity must be attributed to conditions which come into play during antenatal life—that is, that the deformity is congenital, the view originally advanced by Naegele. Since his time discussion has ranged about the possibility of an inflammatory causation of the condition, until in 1900 Breus and Kolisko asserted that this condition was always the result of inflammatory disease. Williams investigated his case thoroughly in an attempt to ascertain how far it seemed to support the contentions of these authors. He states that his studies led to no definite conclusions, but that they tend to indicate in a certain proportion of cases that a final conclusion is not so easily reached as might be gathered from the sweeping conclusions of previous authors.

Pathology.

588. The Parotid Secretion in Mumps.

F. ROCCHI (*Il Policlinico*, Sez. Med., November 1st, 1929, p. 541) made repeated attempts to transmit mumps to rabbits by injecting testicular fluid from patients with mumps orchitis directly into the parotid in five cases, and into the vas deferens in one case, but always with negative results. Inoculation of the blood of a mumps patient at the height of the disease into the peritoneum of guinea-pigs was similarly ineffective. Catheterism of Stensen's duct in thirty cases of mumps in adults and various control cases, amounting in all to another 250 examinations, showed that the parotid secretion in mumps undergoes a considerable change. In the majority of cases this change is represented by an abolition of the secretion, while in a small percentage there is a more or less considerable diminution. The type of secretion in individual cases (diminution or absence) is not influenced by gustatory or pharmacodynamic stimuli, whether mild or strong, such as lemon juice, tartaric acid, or the injection of 1 cg. of pilocarpine. The average curve of secretion in various stages of the disease showed that the secretion was diminished on the first day of the disease, and rapidly fell to a low level, for about a week varying from 1 to 2 c.cm. an hour. The quantity of albumin in the saliva varies between 0.01 and 0.11 gram, which indicates a considerable increase over the normal. The parotid saliva in mumps showed many characteristic morphological elements—namely, neutrophil polymorphonuclears, lymphocytes, monocytes, gland cells, and epithelial cells from the lining of the ducts—in various stages of preservation. The distribution of these elements in various days of the disease did not support the classification of mumps into three stages as maintained by Sicard and Dopter. The course of the disease was accompanied from the very first day by elimination mainly of the neutrophil polymorphonuclear and gland cells. This characteristic phenomenon, which gradually disappeared as recovery proceeded, is thought to form an important distinction between infective and epidemic parotitis. *Finally, the author points* out that the behaviour of the salivary secretion and its various characters demonstrate the essentially parenchymatous nature of the lesion in the parotid gland.

589. The Effect of Repeated Haemorrhage on Healing Fractures.

A. RALLO (*Rif. Med.*, October 5th, 1929, p. 1345) has investigated the influence of repeated bleedings on the rate of union of long bones after fracture. In 15 rabbits the radius of one side was cut through by scissors; from 10 of these animals blood corresponding in amount to one-seventh of the total blood volume was removed by heart puncture, at first daily for seven days, and then every two, three, and four days until the thirtieth day; the remaining five rabbits were treated as controls. The first rabbit was killed on the tenth day, after eight bleedings; in the section prepared from the seat of fracture the haemorrhagic area was mostly represented by amorphous detritus with some new-formed fibrous tissue, in the midst of which were necrosed spicules of bone; at the margin of the fracture were blood spaces suggesting new blood-vessel formation; the periosteum was separated from the bone and the space was filled with haemolymph elements and young cartilage cells. In a control animal killed at the same date the seat of fracture was completely filled with haemorrhagic detritus, there was no production of fibrous tissue, the splinters of bone were not necrosed, there were no blood spaces suggesting new blood-vessel formation, and the periosteum showed no proliferative activity. In sections from a rabbit killed on the fifteenth day, after ten bleedings, the haemorrhagic debris was largely replaced by fibrous tissue and diffuse collections of cartilage cells, showing active cell division; and there was also an amorphous substance which suggested early calcareous deposit. In sections from a control animal at this date the haemorrhagic stage persisted, the original bone splinters were not altered, there was only a scanty production of cartilage cells, and no evidence of calcareous deposit. Similarly prepared sections from animals killed at the twentieth, twenty-fifth, and thirtieth days, which are well illustrated by photomicrographs, confirmed the author in his conclusion that the healing of fractures is greatly accelerated by repeated removal of blood, which increases the fixing capacity of the tissues for salts of calcium.

590. The Tuberculin Reaction after Vaccination with B.C.G.

R. DEBRÉ and E. COFINO (*C. R. Soc. de Biologie*, November 15th, 1929, p. 513) have made a series of tests to ascertain the proportion of infants developing a positive tuberculin reaction after oral vaccination with B.C.G. during the first few days of life. All the infants belonging to the experimental and the control group were born of tuberculous parents and had been separated at birth; they were brought up in an environment free from tuberculosis. The technique of examination consisted in performing a Pirquet test with crude tuberculin. If this proved negative, 1/10 mg. of tuberculin was then injected intradermally (Mantoux's test); if this was negative, 1/2 mg. was injected; and finally, if this proved negative, 1 mg. was injected intradermally. Using this technique, which was devised to bring out the lesser degrees of tuberculin sensitivity, the authors found that 141 control infants, who had not been vaccinated with B.C.G., failed to react at all. On the other hand, of 132 vaccinated infants, ranging in age from under 3 months up to 4 years, 117, or 88.6 per cent., reacted positively. These results indicate that the majority of infants vaccinated by the mouth with B.C.G. develop a definite sensitivity to tuberculin. They likewise show that Mantoux's test is more delicate than Pirquet's, for of the 117 positive reactions only 42 were obtained by the latter method. In another paper (ibid., p. 516) the authors analyse the relationship of age to tuberculin sensitivity. It was found that of 58 infants under one year old, on whom all the tests were practised, only 1, or 1.7 per cent., failed to react; of 45 infants from 1 to 2 years old, 3, or 6.7 per cent., failed to react; while of 29 infants from 2 to 4 years old, 11, or 37.9 per cent., failed to react. Moreover, it was found that the older the child became, the greater was the amount of tuberculin that had to be injected in order to obtain a positive reaction. The authors conclude that tuberculin sensitivity diminishes in vaccinated subjects, particularly after the age of 2 years.

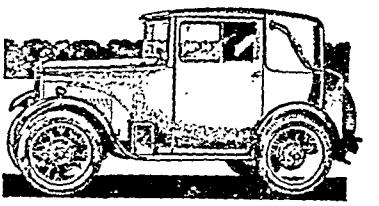
EVERY GOOD FEATURE—



ALTHOUGH the Triumph Super Seven engine develops amazing power for so small a power unit, there is no "roughness" or vibration—the three-bearing crankshaft prevents it.

This absence of vibration means longer life for the power unit—for the whole car.

Smoothness of running spells comfort for the owner and for those who ride with him or her.

Ask an engineer—he will corroborate these facts: have a trial run and that will convince you.

Every good feature is found in this, "the finest small car in the world"—the Triumph Super Seven.

There are eleven body styles to choose from in a wide range of colour schemes.

Dunlop tyres and Lucas electrical equipment standard.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombieres treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms prospectus etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—
Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. (Toll Call from London.)

Preliminary Examinations
The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical and Dental Students in London and at Provincial Centres in March, June, September, and December. For Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1.

EPSOM COLLEGE

Established in 1855 as a Public School with a Royal Medical Foundation.

Patron: HIS MOST GRACIOUS MAJESTY THE KING.
President: The Right Hon. the Viscount Burnham, G.C.M.G.
Treasurer: Sir William Hale-White, K.B.E., M.D.
Chairman of the Council: Raymond Crawfurd, Esq., M.D., F.R.C.P.
Vice-Chairman of the Council: Sir John F. H. Broadbent, Bart., M.D.
Head Master of the School: Arnold C. Powell, Esq., M.A.

EPSOM COLLEGE is in a healthy situation at a considerable elevation and on the edge of the Downs. It contains a valuable Library; a Museum; five Laboratories—two Chemical, two Physical, and one Biological; a Lecture Theatre; a Carpenter's Workshop; an Armoury; a Gymnasium; a Swimming Bath; and extensive grounds of close upon 80 acres.

Within the College grounds, but detached from the main building, are a Chapel, a Sanatorium, and a suitably fitted isolation hut.

For boys who have matriculated at the University of London, and who desire to enter the Medical Profession, the First Medical Examination of that University is conducted at Epsom College, and they are spared the expense of going to London for the purpose.

The General Council of Medical Education and Registration of the United Kingdom has included Epsom College in the list of Recognized Institutions approved of by that Council as places at which medical study may be commenced; and the College has been recognized as a School of Science by the Royal Colleges of Physicians and of Surgeons for the purpose of their Conjoint Diplomas.

Boys are also prepared for the Army, Navy, Air Force, Civil Service, the Universities, and for mercantile careers.

Ten Medical Scholarships, differing in value, are awarded annually at the Hospital Schools in London, and 32 leaving Scholarships, ranging in value from £15 to £105, are awarded under varying conditions, some of them annually, but most of them tenable for several years. Besides these, there are one "Dr. Robert Thomson and Phyllis Broughton" Open Entrance Scholarship of £120 a year; one "Domett Stone" Open Entrance Scholarship of £50 a year; and four "Salomons" Entrance Scholarships of £50 a year each. "Hugh Vardon" Scholarships of £24, and Junior Open Scholarships of £60, are awarded annually.

ANNUAL FEES.—Sons of Medical Men, £135. Those who are not the sons of Medical Men, £155. Day Scholars, £57. These fees cover all the "extras" which used to be charged for separately under the heading "Consolidated Charges."

NEW SANATORIUM.

The provision of a new Sanatorium is a pressing need. The present Sanatorium is unsatisfactory in its accommodation and arrangements, is uneconomical in working, and affords no facility for isolating infectious cases. The Medical Officer of the College, with the aid of an experienced hospital architect, has prepared outline plans for a model Sanatorium, with an Isolation Wing, the total cost of which will be about £30,000.

The Council are now actively engaged in an effort to secure the necessary money, and already a sum of over £7,500 has been collected. A donor of £10,000 may give his own name or the name of any person whom he desires to commemorate to the main Sanatorium, a donor of £5,000 may do likewise to the Isolation Wing: while a large ward may be named for £3,000 or a small ward for £1,000, and a single bed for £100.

An Institution which has its roots in the science of medicine ought to be possessed of a Sanatorium that should stand out as a model for all other public schools. The provision of a suitable Sanatorium is not only a hygienic matter but would have incidentally an important educational aftermath, for the vacated building would, with a limited amount of internal adaptation, afford excellent residential quarters for some forty more boarders, and so enable the College to house many of the applicants whom it is compelled to decline each year.

Contributions should be sent to the Secretary of the College, 49, Bedford Square, W.C.1, and made payable to the "New Sanatorium Fund."

WAR MEMORIAL: THE CHAPEL.

The Old Epsomian Club instituted a War Memorial Fund for the purpose of enabling the Nave of the Chapel to be rebuilt in harmony with the new Chancel, and of placing in it a suitable monument bearing the names of old Epsomians and Epsom Masters who sacrificed their lives in the war.

The work of rebuilding the Chapel was completed by the end of 1924. As a further sum of about £1,970 is required to pay off the deficiency on this work, the Council earnestly appeal to Old Epsomians and other friends of the College for further contributions. The War Memorial Fund is still open, and Cheques should be drawn in favour of the "Epsom College War Memorial Fund," and sent to the Secretary, 49, Bedford Square, W.C.1.

Donors to this Fund will receive the same voting privileges as those given to contributors to the Royal Medical Foundation of the College.

ROYAL MEDICAL FOUNDATION.

FIFTY FOUNDATION SCHOLARS receive an education of the highest class in Epsom College, and are boarded, clothed, and maintained at the expense of the College. They must be elected, after approval by the Council, from among the sons of necessitous Medical Men who have been Registered Medical Practitioners for five years.

FIFTY ORDINARY PENSIONERS, who must be legally qualified Medical Men registered for five years, or the Widows of such, receive an annual pension. They must be not less than 60 years of age at the time of their application for admission as candidates.

The Ordinary Pensioners and the Foundation Scholars are elected by the Governors, voting by ballot, and having votes in proportion to the amount of their contributions. There is one election in the year, namely, in June.

The Ordinary Pupils, the majority of whom are sons of Medical Men, pay fees which cover the entire cost of their board and education.

A sum of close upon £9,000 is required annually to maintain fifty Foundation Scholars and fifty Pensioners, yet this leaves much destitution in the profession untouched. The Council earnestly plead for more and larger subscriptions, so that they may extend the work to the relief of this distress.

The profession and the public are therefore asked to make the Royal Medical Foundation attached to the College a refuge in time of trouble for all those members of a great profession and their children who fall on evil days.

Donors of 10 guineas, and collectors of 20 guineas, are Life Governors of the College; subscribers of one guinea annually are Governors during the continuance of their subscriptions.

J. BERNARD LAMB, Secretary.
Office: 49, Bedford Square, W.C.1.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One *half* of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:	Per annum.
	£
After 17 years' service for pension	400
„ 18 „ „ „	430
„ 19 „ „ „	460
„ 20 „ „ „	500
„ 21 „ „ „	540
„ 22 „ „ „	580
„ 23 „ „ „	620
„ 24 „ „ „	660
„ 25 „ „ „	700
„ 26 „ „ „	750
„ 27 „ „ „	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet early in January to make nominations, and the selected candidates will be required to attend a course of instruction commencing on or about the 1st February, 1930.

Post-Graduate Teaching, West London Hospital.

Continuous Clinical Instruction daily from 10 a.m. to 4 p.m.—Post-Graduates may enrol at any time for any period from 1 week to 3 months.—Special facilities for "Study Leave."—Anæsthetic Courses.—Clinical Assistantships.—Annual Membership Tickets at Special Terms available for General Practitioners who wish to attend the Hospital Practice at irregular intervals.

Prospectus from Sir Henry Simson, K.C.V.O., Dean, West London Hospital, Hammersmith, W.6.

Wilts County Council

APPOINTMENT OF ASSISTANT SCHOOL DENTIST.

The Wilts County Council invite applications for the appointment of an Assistant School Dentist, to work in the Department of the County School Medical Officer, at a salary of £450 per annum.

Subsistence allowance in accordance with the County scale will be paid.

The officer appointed must be duly qualified and registered, and will be required to reside in or near Trowbridge.

The appointment will be made subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Applications, on forms to be obtained from the undersigned, and accompanied by copies of not more than three recent testimonials, must be delivered in envelopes, marked "School Dentist," not later than the first post on Friday, January 3rd, 1930.

Canvassing, either directly or indirectly, will disqualify.

County Offices, Trowbridge, Wilts. December 10th, 1929. W. L. BOWN, Clerk of the Council.

Borough of Macclesfield.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Council invite applications for appointment as Medical Officer of Health and School Medical Officer.

The person appointed will be required to devote his whole time to his duties, and will take entire charge of the Public Health work of the Council, including Maternity and Child Welfare, Mental Deficiency, and all School Medical Services, and of the Council's Isolation Hospitals, and will also act as Supervising Officer under the Midwives Acts and Certifying Officer under the Council's Superannuation Scheme when established.

The commencing salary will be £800 per annum, with increments of £25 to a maximum of £900. Candidates must not be more than 35 years of age and must be registered Medical Practitioners holding a qualification in Public Health or State Medicine.

The appointment will be subject to three calendar months' notice on either side.

Applications, stating qualifications, endorsed "Medical Officer of Health," accompanied by copies of not more than three recent testimonials, should be addressed to me not later than January 8th, 1930.

Town Hall, Macclesfield. December 11th, 1929. F. R. OLDFIELD, Town Clerk.

Birmingham Union.

SELLY OAK HOSPITAL.

TWO CASUALTY OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for the appointments of Casualty Officers (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 340 beds divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children, and Infectious Sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-therapeutic, Massage, and Sunlight Departments. Over 2,200 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time.

The officers appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to them by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointments is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointments may be obtained from the Medical Superintendent, Mr. R. P. STANLEY KELMAN, M.B., F.R.C.S. (Eng. & Edin.) at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Wednesday, January 8th, 1930.

Union Offices, Birmingham. December 12th, 1929. C. P. BEECH, Clerk to the Guardians.

Birmingham Union.

MONYHULL COLONY.

RESIDENT ASSISTANT MEDICAL OFFICER (Female).

Applications are invited from fully qualified Medical Practitioners for the above appointment at Monyhull Colony, King's Heath, Birmingham. Candidates should have held House appointments, and experience with mental patients will be an added qualification.

The Colony accommodates approximately 1,200 epileptic and feeble-minded patients, and comprises Adults' and Children's Sections. The Colony is certified under the provisions of the Mental Deficiency Acts, 1913 to 1927, and the Education Act, 1921.

The person appointed will be required to assist in the general medical work of the Colony and to undertake such other duties as may be assigned to her by the Guardians or the Medical Superintendent, and, should occasion arise, to assist at any other Institutions under the control of the Guardians.

The minimum and maximum of the scale of salary attached to the appointment are £250 and £350 per annum respectively, and the salary of the successful candidate will be fixed within these limits according to qualifications and experience. In addition, full residential emoluments will be provided. A percentage deduction will be made from the salary and value of emoluments in respect of superannuation, and for this purpose emoluments are valued at £200 per annum.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded to me as soon as possible, and in any case not later than Saturday, January 4th, 1930.

Canvassing the Guardians, directly or indirectly, will disqualify.

Union Offices, Edmund Street, Birmingham. December 16th, 1929. C. P. BEECH, Clerk to the Guardians.

The Guest Hospital and Eye INFIRMARY, DUDLEY.

(General Hospital—104 Beds.)

Applications are invited for the post of ASSISTANT HOUSE SURGEON, to commence duty on January 16th, 1930. Duties include Medical, Surgical, Eye, Ear, Nose, and Throat, and Venereal Diseases work. Salary £150 per annum, with furnished apartments, board, and laundry. Candidates must be fully qualified and registered. Applications, stating age, qualifications, and experience, and accompanied by copies of testimonials, to be sent to the undersigned not later than December 31st.

H. RAYMOND HURST, Secretary.

The Guest Hospital, Dudley. December 16th, 1929.

County Borough of SOUTHAMPTON.

APPOINTMENT OF SCHOOL DENTIST.

Applications are invited for the position of an Assistant School Dentist to carry out the Dental examination, treatment, etc, of elementary school children.

The gentleman appointed must be fully qualified and registered. He will hold office during the pleasure of the Council and will be required to devote the whole of his time to the duties of the office and to act under the direction of the School Medical Officer.

Salary £450 per annum.

The Local Government and Other Officers Superannuation Act, 1922, will be applicable to the appointment, and contributions to the Superannuation Fund will be deducted from the salary. The selected candidate will be required to pass a satisfactory medical examination.

The appointment will be determinable by two months' notice on either side.

Forms of application may be obtained from the Medical Officer of Health, Municipal Offices, Southampton.

Application on the prescribed form, endorsed "School Dentist," together with copies of not more than three recent testimonials, must be delivered at the Town Clerk's Office, Municipal Offices, Southampton, on or before January 4th, 1930.

REGINALD H. MEGGESON, Town Clerk.

County Borough of Great YARMOUTH.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT TUBERCULOSIS OFFICER.

Applications are invited for the position of Assistant Medical Officer of Health and Assistant Tuberculosis Officer. Salary £600 per annum.

The gentleman appointed will be required to devote the whole of his time to the service of the Corporation, and in addition to acting as Assistant Tuberculosis Officer will be required to assist in the general work of the Health Department, working for all purposes directly under the Medical Officer of Health, who is also Tuberculosis Officer.

Candidates must have had at least three years' experience of their profession since qualification; be able to show special experience in the diagnosis and treatment of tuberculosis; and should hold a Diploma in Public Health.

The appointment is subject to the approval of the Ministry of Health and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, stating age, marital state, qualifications, tuberculosis experience, and general experience, together with not more than three recent testimonials, should be delivered to the Medical Officer of Health, Town Hall, Great Yarmouth, marked "Assistant Medical Officer," not later than January 4th, 1930.

Dated this twelfth day of December, 1929.

Town Hall, Great Yarmouth. W. EDGAR STEPHENS, Town Clerk.

Bolton Union.

TOWNLEYS HOSPITAL.

Wanted for the Townleys Hospital, Farnworth, near Bolton, a SECOND ASSISTANT MEDICAL OFFICER (male) for a period of one year.

The salary will be at the rate of £225 per annum, and rations, furnished apartments, attendance, washing, etc.

The Hospital has accommodation for 550 patients, is a recognized training school for nurses, and has a Medical Superintendent and three resident Assistant Medical Officers.

Forms of application, together with conditions of appointment (for which a stamped addressed foolscap envelope must be enclosed), may be obtained from me.

Last day for applications January 6th, 1930.

28, Mawdsley St., Bolton. December 13th, 1929. H. I. COOPER, Clerk to the Guardians.

Swansea County Borough.

MALE ASSISTANT MEDICAL OFFICER.

The Swansea Borough Council invite applications from duly qualified Medical Practitioners for the post of Male Assistant Medical Officer to assist with the Medical Services of the Corporation.

Hospital resident and special experience of refraction and ear, nose, and throat work, school medical service, and maternity and child
rable; the D.P.H
the foregoing, is
er annum, subject
of Education and
the Ministry of Health.

Applications, on special forms, which can be obtained from Dr. Thomas Evans, Medical Officer of Health, Public Health Office, Swansea, to be sent in not later than December 31st.

Hampshire County Council.

ASSISTANT COUNTY MEDICAL OFFICER.

Applications are invited for the post of Assistant County Medical Officer. Preference will be given to a woman with experience in maternity and child welfare work, including maternity centres and ante-natal clinics, and in the treatment of venereal diseases. Possession of a Diploma or Degree in Public Health is essential, and previous experience in Public Health work, tuberculosis, and medical inspection of school children will be considered an advantage.

Salary £600 a year, rising by increments to £750 (subject to deductions under the Local Government Officers Superannuation Act), in addition to travelling expenses and subsistence allowances.

Applications, with copies of not more than three testimonials upon a form which, with the conditions of appointment, may be obtained from the County Medical Officer, The Castle, Winchester, should be sent to him not later than January 3rd, 1930. Canvassing is prohibited.

Durham County Mental Hospital

Wanted, a JUNIOR MALE ASSISTANT MEDICAL OFFICER, with a sound knowledge of Bacteriology and Pathology, competent to take charge of Laboratory. Age not over 30 years, unmarried. Must be fully qualified and duly registered.

Commencing salary £350 per annum, rising by annual increments of £25 to £450 (if in possession of D.P.M. an additional £50), with board, lodging, washing, and attendance.

The appointment will be made under the provisions of the Asylum Officers Superannuation Act, 1909, and for this purpose the emoluments are valued at £135 per annum.

Applications, stating age, qualifications, etc., with copies of three recent testimonials, will be received up to the 31st instant, and should be addressed to the MEDICAL SUPERINTENDENT, Winterton, Stockton-on-Tees, Co. Durham.

December 14th, 1929.

The London Female Lock Hospital,

285, Harrow Road, London, W.9.

The Board of Management invite applications for the appointment of HOUSE SURGEON (male or female) at the Female Lock Hospital. Salary at the rate of £150 per annum, with furnished rooms, full board, and washing. Candidates, who must be doubly qualified and duly registered, should send in their applications by January 6th, 1930, accompanied by copies of three recent testimonials, to the Secretary, from whom further particulars can be obtained. The appointment is for six months commencing February 12th.

APPOINTMENTS.—Contd.

Lowestoft and North Suffolk HOSPITAL, LOWESTOFT.

JUNIOR HOUSE SURGEON (male) required. Salary £120 per annum, with board, residence, and laundry. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

Resident Medical Officer required

immediately for LEEDS JEWISH HERZL-MOSER HOSPITAL. Salary £100 per annum, full board. Ample time for Post-graduate work.—Apply, Secretary, Herzl-Moser Hospital, Leopold Street, Leeds.

Parish of Newcastle-upon-Tyne.

ASSISTANT RESIDENT MEDICAL OFFICER (Male).

The Guardians of the Poor of the Parish of Newcastle-upon-Tyne invite applications for the appointment of an Assistant Resident Medical Officer (male) at their WINGROVE HOSPITAL, Westgate Road, Newcastle. Salary £250 per annum, with residential allowances valued at £100 per annum. The appointment will in the first instance be for a period of six months, but may subsequently be extended at the discretion of the Guardians. The Hospital contains 650 beds and offers valuable clinical experience to keen students in mental, venereal, maternity, X-ray and electrical therapy. The Hospital is a training school for nurses and midwives, and has a consultant and resident staff. The person appointed will act under the Medical Superintendent and may be required to lecture to probationers. The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1896, and to the provisions of the Local Government Act, 1929. Applications must be made on forms which may be obtained at my office or on receipt of a stamped addressed foolscap envelope, which forms, duly completed, must be received by me not later than Saturday, January 4th, 1930.

By Order,
127, Pilgrim St., GLADSTONE WALKER,
Newcastle upon Tyne. Clerk to the
December 18th, 1929. Guardians.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782, 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent..

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

DOCTORS THEMSELVES
PRAISE
"RYVITA CRISPBREAD"

Dr. . . . . Harley Street, W.1.—"I am already using and prescribing 'RYVITA,' and I think it excellent."

Dr. . . . S.W.1.—"This product solves the question—the importance of which has recently been brought into such prominent notice:—viz., of finding a wholemeal bread, pleasant to the taste, and demanding thorough mastication."

Dr. . . . . Ledbury.—"Please send 10 lbs. of 'RYVITA.' Everyone prefers the 'RYVITA' to bread. It is *far superior from* the point of view of health."

Dr. . . . Yeovil.—". . . . I have recommended 'RYVITA' to a large number of my patients, who are highly delighted with it."

Dr. . . . Crewkerne.—". . . Up to now I think I have consumed personally about 30 lbs. of 'RYVITA.' My boys love it; *scores of my* patients are eating it."

Dr. . . . Sinithwaite.—". . . . It is now several years since we first used 'RYVITA'; indeed, my wife had to send direct to you first by post, as we could not procure it locally. Since then the sale of 'RYVITA' has increased by leaps and bounds, till now every *decent class shop* in Huddersfield sells it."

"Since we first began eating 'RYVITA' we have never ceased to recommend it . . . it is a remarkable thing that wherever we go now we find 'RYVITA' on the table."

"As a medical man I am very glad to see this as I feel sure it is conducive to better health."

Dr. . . . . Droitwich.—"Kindly send me another 10 lbs. It is the very thing I have been looking for, for years. My household like it very much."

Dr. . . . . Eastbourne.—"Very delicious to eat."

"*Dr. . . . . S.W.1*, has recommended and distributed several packages to patients of supply he purchased last week, and would be glad of samples for this purpose."

Dr. . . . . Almondsbury.—"I am exceedingly pleased with 'RYVITA,' and personally I have been freer from indigestion while taking it than for many months; consequently, I am recommending it freely in my practice. Send me a supply of samples to give to my patients. I have given several patients some of my own stock to start on."

Dr. . . . . Southport.—"Have already induced a number of my patients to use 'RYVITA.' In cases where there has been habitual constipation, the result of eating 'RYVITA' has been excellent and the constipation has yielded without the use of aperients. You cannot make 'RYVITA' too widely known."

(Later letters.)

"I have nothing but good to report regarding 'RYVITA CRISPBREAD.' It has been excellent in all cases of constipation. Send me about 25 booklets, also a sample of 'RYVITA' to patient at address below."

"Some little time ago you brought 'RYVITA' to my notice. I got a large number of my patients to take it regularly. Some of these have been supplied in shops with 'something just as good.' Some are now buying an article which to my mind and experience is not as good as 'RYVITA.' There should not be this risk of their having something else palmed off on the customers."

NOTE.—The originals of all the above letters, are, of course, available, and can be seen by any persons properly interested.

(We could fill many pages with similar letters from Medical Men.)

THE MECHANICS OF THE DIGESTIVE TRACT

ALVAREZ has shown how very sensitive is the rectum to any increase in internal pressure. Very slight abnormality of distension suffices to produce headache and a feeling of malaise. Zimmerman found that a rise in rectal pressure of even so little as 3 mm. of mercury produces a definite effect on consciousness.

No matter what may be the explanation of these psychic manifestations of constipation, there is no doubt that the abdominal discomfort associated therewith is almost entirely due to disturbances in the tone and rhythmic movements of the intestinal wall.

Both groups of symptoms can nearly always be avoided or removed by a regular morning glass of Eno's "Fruit Salt," taken just before the early cup of tea. This draught is pleasant and refreshing; and, by retaining fluid in the bowel, promotes steady and harmonious paristalsis and gentle and painless elimination. Being free from all admixture of the unpleasant mineral sulphates (Epsom and Glauber), Eno has no need of sugar or artificial flavouring agents to disguise its natural taste. Its freedom from sugar makes it a specially suitable preparation for use in diabetes.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.
